Antrim.—The Commissioners for the Control of Lunatic Asylums will receive sealed tenders up to 10 a m. on May 1 for the supply and erection of an electrical installation at County Antrim Lunatic Asylum. The tender should be sent in a sealed envelope, endorsed outside "Tender for Electric Lighting, County Antrim Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and should be accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tenders, and copy of specification, which has been prepared by Mr. J. H. Greenhill, M I E E., will be issued on application to the office of the Board of Control of Lunatic Asylums, Dublin, on deposit of £3, which will be returned to all persons who have sent in bona fide tenders. Plans can be seen at the office of the architect, Mr. John Lanyon, Northern Bank-chambers, Royal-avenue, Belfast.

Coventry.—The Electric Lighting Committee require tenders for the supply and erection of the following plant: (Section A) boiler-house plant—boilers and fittings, mechanical stokers and economiser, feed pump, etc.; (Section B) engine-house plant—steam-engine, alternator, oil filter, fittings, etc., steam, exhaust, feed blow-off, sundry pipes, valves, etc. Tenderers are at liberty to tender for either section, but not for part of a section. The ground plan of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation Ormond House, Great Trinity-lane, London, E.C., on and after 24th inst. on payment of £2. 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to Mr. Lewis Beard, town clerk, St. Mary's Hall, Coventry, and delivered by May 12.

London, S.E.—Tenders are required for supplying and fixing complete electric light machinery required for the public baths and wash-houses now in the course of erection in Manor-place, Walworth-road, for the Commissioners for Public Baths and Wash-houses for St. Mary, Newington. Any person desiring to tender may, after depositing £5. 5s. with the architect, Mr. E. B. I'Anson, 7A, Laurence Pountney-hill, Cannon-street, E C. (to be returned on receiving a bona fide tender), obtain a copy of the quantities and inspect the drawings and specification at his office between 11 a.m. and 2 p.m. A tender will only be accepted on condition the contractor signs a declaration that he will pay to the workmen employed by him not less than the recognised trade union rate of wages in each branch of the trade. Tenders to be endorsed on the envelope "Tender for Engineers' Work to the Public Baths and Wash-houses, Manor-place, Walworth-road, S.E.," and to be delivered at the office of Mr. L. J. Dunham, clerk, Vestry Hall, Walworth-road, S.E. by 3 p.m. on 29th inst.

Shooter's Hill (London).—Tenders are wanted by May 6 for the provision and fixing of electric bells, telephones, fire alarms, etc., at the Brook Fever Hospital, Shooter's Hill, S.E., for the Metropolitan Asylums Board. Copies of the specification form of tender, conditions of contract, and of the drawing, which have been prepared by Prof. Kennedy, LL.D., F.R.S., of 14, Old Queen-street Westminster, S.W., can be obtained at the chief offices of the Board on and after 16th inst. upon depositing gold or Bank of England note to the value of £5 (which will be returned only to those who send in a bona fide tender in accordance with the terms of this advertisement, and who return the drawing, specification, and conditions of contract). Tenders, which will only be received on the lithographed form supplied by the Board, must be sealed and endorsed "Tender for Electric Bells, Telephones, etc., Brook Hospital," and must be delivered at the Chief Offices, Norfolk House, Norfolk-street, W.C., by 2 p.m. on May 6. Unless the tender be accompanied by the specification, conditions of contract, and the drawing it will not be considered.

RESULTS OF TENDERS.

Harrogate.—The tender for the construction of a steel roof for the electric lighting shed by Messrs. J. Abbott and Co., of Gateshead, for £623. 4s. 9d., has been accepted by the Town Council.

Sunderland.—The contract for fuel economiser in connection with the extensions at the Corporation electric light station has been placed with E Green and Son, Limited, of Manchester and Wakefield.

Birmingham.—The contract for the wiring and fitting of the new general hospital has been placed with the Birmingham Electric Supply Company, Limited, and the supply of electricity required for the lighting, and also for power purposes, will be from the company's supply mains.

Brussels.—The successful tender for electric light buildings and other work at the Luttre station, on April 15, was that of M. V. Ernaelsteen, Waterloo, at 11,044fr. The lowest tender for work in connection with the water supply and electric lighting at the Marbehan station was that of Messrs. T. Hustin, Ethe, at 34,814fr.

Bradford.—The tenders have been received for the new electricity station works at the junction of Valley-road and Lionel-street, for the Corporation. The accepted tenders were: building—J. Moulson and Sons, Bower-street, excavators and masons; H. Thirkill, Nelson-street, carpenter and joiner; Hill and Nelson, Edmund-street, slaters; Roberts and Co., Limited, Union Foundry, Cutler Heights, ironfounders; R. Townend, Croft-street, plumber and glazier; T. Bolton, Tudor-street, plasterer and concretor; G. J. Walton, Great Horton-road, painter; Wood Block Flooring Company, 11, Queen Victoria-street, London, E.C., wood block flooring; A Broxup and Sons, Great Horton, reservoir and tank; Coalbrookdale Company, Limited, Coalbrookdale, Shropshire, gates and railings. Electrical plant: Epstein Electric Accumulator Company, Limited, Victoria-mansions, 28, Victoria-street, London, S.W., battery; Cole, Marchent, and Morley, Prospect Foundry, surface-condensing plant; British Insulated Wire Company, Limited, Prescot, Lancs., cables; J. Booth and Bros., Rodley near Leeds, travelling crane; J. Spencer, Globe Tube Works, Wednesbury, Staffs, steam and exhaust pipes. Rest of Bradford.

BUSINESS NOTES.

West Ham.—Mr. G. H. Risch has been appointed borough electrical engineer.

Coventry.—The new premises built for the London and Midland Bank are lighted by electric light.

Perth—A handsome electric organ has been erected in Kinnoull Parish Church at a cost of £1,000.

Folkestone.—At the meeting of the Town Council the town clerk reported as to the position of the electric light order.

Crieff.—Arrangements are being made to have the telephone extended to the town in connection with the National Telephone Company.

Budapest.—The accounts of the Budapest Electric Tramway Company show a profit allowing of a dividend at the rate of 10 per cent.

Dudley.—The Streets and Gas Committee are going into the question of the gas supply thoroughly, and will fully consider the possibilities of electric lighting.

West India and Panama Telegraph Company.—For the two weeks ended April 15 the receipts were £2,802, as against £2,307 for the corresponding period of 1895.

Dublin.—The Rathmines, Blackrock, and Dundrum Tramways Company have received sanction from the Township Commissioners to construct two miles of electric tramway. The cost is estimated at about £55,000.

Chelmsford.—Messrs. Crompton and Co. have come to terms with the trustees of the Johns estate. Several acres of land near the Writtle-road Cemetery have been secured for the site of the firm's new electrical works.

Reading.—At the annual Vestry meeting of the parish of St. Lawrance, the question of lighting the church by electricity was discussed, and referred for consideration to a meeting of the Church Board, which will be summoned shortly.

The London Tramways Scheme—The promoters of the project for amalgamating the London tramlines and working them by electric traction have got as far as circularising the members of the London County Council on the subject.

German-American Cable.—A correspondent of the *Financial Times* has called attention to the fact that the German Government have granted a concession for a German cable to the United States, and to its possible effect on the English companies' receipts.

Eastern Telegraph Company, Limited.—The Company announce the payment by warrants on May 1 of interest for the half-year ending April 30 on the 4 per cent. mortgage debenture stock. The transfer books will be closed from 27th inst. to May 1, both days inclusive.

Portsmouth—At the last meeting of the Town Council, a recommendation by the Electric Light Committee to extend the low-tension electric light mains from Elm-grove through Yarborough-road and The Retreat to Grove-road, at an estimated cost of £100, was agreed to.

Digitized by Google

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending April 19 amounted to £1,151, as compared with £1,386 in the corresponding week of the previous year, being a decrease of £235.

Grimsby.—The estimate for public lighting by gas for the next six months amounts to £1 800, which the Town Council consider a very heavy item, and they wish they could see their way to make it less At the last meeting the chairman told them their only chance was in electric lighting.

Eastern and South African Telegraph Company, Limited.—The Company announce the payment by warrants on May 1 of interest on their 4 per cent. Mauritius subsidy debentures for six months to 30th inst. The transfer books will be closed from 27th inst. to May 1, both days inclusive.

Tooting (Surrey).—The Wandsworth and Clapham Guardians are going to reconstruct St. Joseph's College, and the original scheme provided for an item of £367 for electric lighting, but the committee have now left this out, among several other items, because they found that the work would cost more than was at first supposed.

City and South London Railway.—The returns for the week ended April 19 were £921, compared with £856 for the corresponding period of last year, being an increase of £65. The total receipts for the half-year terminating as above were £15 260, compared with £15,218 in the same period of the preceding year, being an increase of £42.

Spain —Plans have been presented to the local authorities of Vich by Ricart and Ca. for a lighting and power plant of 300 h.p. Conditions for the electric lighting of Belchite (Tarragona) are to be published shortly. It is also probable, says the Barcelona *Revista Tecnologico-Industrial*, that electric lighting works will be shortly established in Orviedo

Stockton.—At a meeting of the Cleveland Institute of Engineers, Mr. Dawson, C E , Westminster, read a paper on "Electric Tramways." He related his experiences of the tramways throughout the Continent and in the States, and also those in Coventry, Dublin, and Bristol. The overhead system in the last-named city he especially commended as a model one, and, repudiating the allegations of ugliness brought against the overhead system, spoke of its great economy.

Yarmouth.—The monthly report of the Electric Lighting Committee presented at the last meeting of the Town Council stated that applications had been received from 10 customers for 606 additional lamps, making 160 customers for 7,603 lamps. The income for March was £180. 16s. 8d., and the expenditure £142 8s 11d. The General Electric Company's tender for carbons for the ensuing 12 months was accepted, it being the lowest sent in with satisfactory samples.

Continental Metropolitan Tramways Company, Limited.—The report of the Company for 1895, to be submitted at the ninth ordinary general meeting held in London to-day (Friday), states that the question of the substitution of mechanical for horse traction has now reached an important stage, the authorities having asked the various companies for information as to terms other than that of the extension of the concession upon which they would agree to the general adoption of mechanical traction.

Leamington.—At a meeting of the Town Council the Lighting, etc., Committee reported that they had considered the letter from the Midland Electric Light Company referred to them, and had had an interview with Mr. Jones, the manager. After discussing the details of the arc light system, they adjourned the further consideration of the question, and instructed the surveyor to obtain results from Oxford, Derby, and Wolverhampton, where the arc light is in use, and especially with reference to the Jandus system.

St. Mary Woolnoth Church.—An amicable arrangement has been come to between the promoters of the City and South London Railway Bill and the members who have been opposing it on behalf of the church of St. Mary Woolnoth. Mr. H. C. Richards will now refrain from moving the rejection of the measure, and the company have agreed to accept an instruction to the committee to consider what provision can reasonably be made for the preservation of the church without preventing the construction of the railway and station.

Worcester.—The Water and Sewage Committee have gone into the cost of steam and electric pumping at the waterworks and have passed the following resolution: "That although this committee are of opinion that the cost of pumping water at the waterworks by electricity is considerably more than if pumped by steam, yet as the electricity department is under the Council's control, this committee recommend the Council to pay for current supplied to the waterworks motors during the financial year of 1896-97 at the rate of 1½d. per unit."

Radcliffe —At the meeting of the Urban District Council, the Electric Lighting Committee reported that Messrs. Boardman and Cunliffe had interviewed the Earl of Wilton's agent with reference to the sale of the plot of land adjoining the sewage works, and that he ultimately agreed to recommend the trustees of the estate to accept the sum of £500 per acre for the plot if the Council would make that offer, but that he could not promise that it would be accepted. It was resolved that the trustees of the Earl of Wilton be offered the sum of £500 per acre for the plot of land adjoining the sewage works in Mount Sion-road.

Warminster.—At a meeting of the Urban District Council the Clerk said the notice putting an end to the contract with Mr. M. Hill for the lighting of the lamp on the fountain by electricity expired on March 25, and it was now for the Council to take the cable from off his premises. Mr. Chambers thought the Council might ask Mr. Hill if he would be prepared to supply the current to light the lamp at £15 a year as before. Mr. Daniell thought Mr. Hill should be allowed to light the lamp as often as he liked, as he had no claim on them for the light and he did not see there was any cause for complaint. The subject then dropped.

Huddersfield.—A Bill has been introduced into the House of Commons to confirm a provisional order granted by the Board of Trade to the Corporation applying the Huddersfield Electric Lighting Order, 1890, to the whole of the county and municipal borough, subject to the Corporation within one year after the commencement of the order laying down and thereafter maintaining suitable and sufficient distributing mains in that portion of Longwood-road situate between Paddock Head and Longwood Church. The Corporation is empowered to manufacture and supply for hire lamps, conductors, machinery, and other apparatus.

Kensington.—Notices and plans have been received from the House-to-House Electric Supply Company relative to extensions of their mains in Drayton gardens, Fulham-road, Sumner place, Selwood-place, Onslow-gardens, and Cranley-gardens, and the Vestry have given permission for the work being proceeded with subject to the conditions that the plans be approved by the Vestry's surveyor and lighting engineer, and that the works be carried out under their supervision and to their satisfaction; that the work be completed within three months of the date of sanction; and that the boxes be efficiently protected against accumulations of gas and water.

Swansea.—Mr. Richard Martin made some sensible remarks at the Corporation meeting in moving the adoption of the Electric Lighting Committee's minutes. These minutes stated that the committee had refused various offers for the provisional order. Mr. Martin said if they had parted with the order, outsiders would have got in for the sake of the plunder. He pointed out that in the case of gas the company had enjoyed a monopoly that had for years given them a considerable revenue. As soon as the electric light was talked about, the company offered to light some of the streets with incandescent gas for nothing, but they had not reduced the price of gas. At present their gas bill came to £5,273.

Dewsbury.—At the meeting of the Town Council the Lighting Committee reported that they had received a letter from the Board of Trade forwarding a copy of regulations for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy Messrs. Jas. Smith and Sons, patent dry cleaners and dyers, Hartley street, have abolished the old method of driving their machines by steam, and are using electricity as the motive power. Already the results have been found to be far more satisfactory than those gained under the old steam system. The firm are about to lay down a larger motor and a 600-light dynamo, and when that is done they contemplate using electricity to heat the flatirons, etc., used in the laundry department.

New Gold Mining Companies and Electricity.—The Woodley's Reward Gold Mines, Limited, registered with a capital of £250,000, takes power to construct, maintain, and work rail and tram roads, electricity supply works, telegraphs, telephones, etc. Registered office, 19, St. Swithin's lane. E C. Hutton's (Bechuanaland) Gold Reefs Development Company, Limited, registered with a capital of £300,000, takes power to construct and maintain rail and tram roads, telegraphs, telephones, etc. Registered office, 69 Moorgate-street, E.C. The Great Victoria Gold Mining Company, Limited, registered by Mayo and Co., 10, Drapers'-gardens, E C., with a capital of £75,000, divided into 75,000 shares of £1 each, takes power to construct, maintain, and work rail and tram roads, telegraph and telephone systems, and electric works, etc.

Newport (Mon.).—Alderman Moses, in bringing up the report of the Electric Committee at the last meeting of the Town Council, referred to the charge of having a defective meter at the museum at the free library. It was the fact that as yet no perfect meter had been found for accurately measuring the amount of electric energy consumed. The meter at the museum had registered a consumption when there was no consumption, but he complained that the Museum Sub-Committee had, instead of working in harmony with the Corporation, gleefully gone on taking the register of their defective meter for weeks before consulting the electrical engineer or any of the officials. He could not find language to condemn such a practice. Some of the meters in the town registered against the interest of the Corporation.

Ayr.—The committee who have been considering the question of tramways have reported strongly in favour of a scheme. As regards the question of the motive power, the committee are unanimously in favour of electricity. They say that electric energy has been found to be specially suitable for tramways in places like Ayr, where the gradients are easy and the traffic medium. The Corporation electricity works will have little to do in the summer, and the tramway would take up the load during the day. The committee find they cannot report further on the proposed undertaking without ascertaining the particulars of similar schemes in actual work, but they intend to keep themselves posted with the latest literature on the subject, and, if the Council approve, to visit some of the most recent ventures in tramway undertakings.

Parliamentary.—In the House of Commons on Monday the Liverpool Electric Supply (Transfer) Bill (sent down from the Lords) was considered and ordered for third reading. The Belfast Street Tramways Bill, the Dublin Southern District Tramways

Digitized by Google

Bill, and the Portsmouth Street Tramways Bill were read a second time. The motion for the second reading of the City and South London Railway Bill was postponed till to day (Friday). The Electric Lighting Provisional Orders (No. 1) Bill having complied with the Standing Orders of the House of Commons, has been sent for second reading. The Bill confirms certain orders made by the Board of Trade under the Electric Lighting Acts of 1882 and 1888 relating to King's Lynn and other places. On Tuesday the Brighton and Rottingdean Seashore Electric Tramroad Bill was read a second time.

Brighton —At the meeting of the Town Council the Lighting Committee reported that they had received a letter from Mr. J. L Neale forwarding a memorial requesting that the portion of Dyke-road between North-street and Goldsmid-road may be lighted by arc lamps. It was resolved that the memorialists be informed that the committee deem it inexpedient to light the portion of the Dyke road referred to with arc lamps, but that the incandescent lamps proposed to be fixed will be an increase of about 50 per cent. on the present gas-lighting. A letter was read from Councillor Stringer requesting that the gas lamp in London-road, at the corner of Baker-street, may be lighted. It was resolved that Mr. Stringer be informed that the matter to which his communication relates is receiving the consideration of the committee. At a further meeting of this committee it was resolved to erect an additional lamp in Baker-street. The proceedings were confirmed without discussion on the motion of Councillor Stafford.

Halifax.—Mr. Rienzi Walton has held a Local Government enquiry respecting an application by the Corporation for sanction to borrow £20,000 for the purposes of electric lighting. The Town Clerk (Mr. K. Walton) said the Corporation had previously obtained borrowing powers for £39,950 for the purposes of electric lighting, but up to the present £43,355 had been expended The Corporation were already supplying 12,000 eight candle lamps, and the demand was rapidly increasing. The existing installation had not yet paid its way, the loss last year, including interest, being £1,090. It had, however, been in existence only 15 months. Councillor Hebden opposed the application, because there was no provision in the loan for developing electricity as a motive power for running machinery The plant was practically lying idle during the day, but if it were then used the committee would be able to reduce the price to consumers He contended that £5,000 of the £20,000 should be used for the development of electricity as a motive power The inspector made a note of the objection.

Blackpool.—The staff and employés at the Corporation electricity works have presented Mr. John Hesketh, the borough electrical engineer, with a handsome case of cutlery, on which was inscribed the words: "Presented to Mr. John Hesketh by the staff and employés of the Corporation electricity works, Blackpool, on the occasion of his marriage with Miss Laurie Hinnell, April 14. 1896." The proceedings were most enthusiastic. Mr. Hesketh, in his reply, said that mention had been made of his early departure, and while another opportunity would be given them of entering into this matter again before he left Blackpool for Queens land, he would ask them to give his successor, whoever he might be, the same hearty co-operation in everything that they had given him, and he was sure his successor could not fail to be fully satisfied. The Corporation have lodged objections to the *locus standi* of the Blackpool, St. Annes, and Lytham Tramways Company and the Lancashire and General Tramways and Carriage Company, both of whom have presented petitions against the Blackpool Improvements Bill.

Dover.—At a Vestry meeting at Buckland, Dover, where the electric light has been installed in the church just over 12 months, the Vicar was very emphatic in his approval of it. He said it had only been in use about a year, but he would not hesitate to say that it was prolonging his life. One of the churchwardens, Mr. Lewis, mentioned that there had been a considerable saving by the use of the electric light in the place of gas At the meeting of the Town Council, the Mayor remarked that in the course of a few days there was every probability of the Council receiving the provisional order for the tramways. The inspector had been down and everything proposed met his approval. Then, perhaps, in the course of a week or two they might hear some of their friends on the virtues of horse, electricity, gas, or petroleum trams, and they would be able to decide which was best. He thought they would be glad to hear that the work had gone on so rapidly and met with none of the delays usual in dealing with Government offices. The Town Clerk remarked that, of course, the order would have to be confirmed by Parliament. The electric light will be laid on throughout the Lord Warden Hotel, and the mains are now being attached.

Southwark (S.E.).—Mr. Howard Smith, barrister, and Mr. J H. Hallett, consulting engineer. the commissioners appointed by the Board of Trade under the Boiler Explosion Acts, 1880 1892, held an investigation last week into the circumstances attending the explosion of a boiler at the Southwark Electric Lighting Station, Bankside. The Board of Trade was represented by Mr. K. E. K. Gough, and Mr. Forman appeared as counsel for the City of London Electric Lighting Company, the owners of the boiler. About 6 p.m. on February 25 last there was a rush of steam and hot water in the stokehold, whereby Peacock, a fireman, was badly scalded. He died on the following morning at Guy's Hospital. The commissioners found that the engineers had acted to the best of the knowledge which they then possessed and had honestly acted on the opinion which they had formed, that the period within which they had directed that the boiler should be cleaned was sufficient to allow an ample margin of safety, which opinion was confirmed by that of independent skilled witnesses. They found that neither the City of London Electric Lighting Company nor any of their employés were to blame for the explosion, and made no order as to costs.

Edinburgh.—At the meeting of the Town Council the treasurer (Mr. M'Crae) made a statement as to the draft provisional estimates of expenditure for the ensuing year. He said that in regard to the Cleaning and Lighting Committee there was an increase on the lighting estimate of £3,865, brought about by the large increase in the electric lighting of the streets. As to the Electric Light Committee, whereas last year they had an expenditure, after allowing for the income, of £1,260, it was estimated the surplus would be £7,490. It was remitted to the Electric Lighting Committee to consider and report upon the charges for electric energy to consumers for the year beginning May, 1896. The Lord Provost's Committee have been directed to consider as to the desirableness of constructing a circular tramway at or near the proposed extended boundary of the city, to be worked by electric or other motor, and connecting the routes at present sanctioned by the Magistrates and Council with the proposed circular route.

Tudor Accumulators.—We have received the price-list for 1896 of the Tudor Accumulator Company, from which it appears that considerable improvements have been made in the cells, as well as a great reduction in the price for batteries to be used for stationary purposes. It is interesting to see that all batteries supplied by this company are guaranteed for two years, and that the manufacturers are prepared to contract for the maintenance of stationary batteries at rates varying from 3½ to 6 per cent. of the list price. The new features are mainly to be found in the cells for traction purposes, in which an extremely high rate of charge has been adopted, and the makers claim that the full capacity can be obtained after 20 minutes' charging. This will allow of the cells being charged *in situ* on the car at the end of the journey. As a guide to the output claimed, it may be said that a cell weighing 80lb. has a capacity of 150 ampere-hours when discharging at 30 amperes, and 120 ampere hours at a discharge rate of 60 amperes. The same weight of cell will also give at extra high-current rates 75 ampere-hours with a discharge at 150 amperes, and would be always charged at this current. The decrease of capacity with an increased rate of discharge appear to us to be less than in some other types of accumulators.

Bedford.—At the quarterly meeting of the Standing Joint Committee the question as to the installation of the shire hall or part of it with the electric light, which was adjourned 12 months ago again came up for discussion. The report of the special committee, as laid before the Joint Committee a year ago, was read and was to the effect that the offices and approaches could be installed for about £80, and the rest of the building for £145. In answer to Mr. Wright, it was stated that the gas bill for the shire hall varied from £24 to £29 per annum. Mr. Pym said his own experience of the incandescent light was that it was difficult to deal with. The glasses often broke and it required constant attention. Before they adopted the incandescent light they ought to make enquiries as to whether it had been so successful as was stated. The electric light was very simple and once they went to the expense of the installation there was no more trouble with it, so it was worth considering. Mr. Pope thought they might try an experiment with an incandescent light to see how it answered. The Clerk said he had tried it in his office, but it was not to his satisfaction. It was an improvement on ordinary gas, but one objection was that even when the brackets were rigid the lamps frequently broke. The matter was referred to the special committee.

Electric Lighting of Trains.—The new system of lighting trains by electric light has been inaugurated on the Glasgow and Edinburgh line of the North British Railway Company. The system, which has already been largely adopted by Southern companies, is the invention of Mr. Arthur B. Gill London, who was present at the opening run, during which the light was exhibited with conspicuous success. The main principle of the system is to light each vehicle independently, and by means of separate accumulators provision is made for keeping each carriage lighted during stoppages. The current is supplied by dynamos which gradually acquire the necessary speed when the train starts, and the general regulation and continuous upkeep of the supply have been carefully provided for. It is claimed by the patentee that the expenditure is largely confined to the initial cost, and that a considerable saving can be effected as compared with gas, the complete supercession of which is considered only a matter of time. The Caledonian Railway Company, after long enquiry regarding the various methods of applying electricity for the lighting of railway carriages, have given orders for an experimental train to be fitted up. In the event of the trial proving satisfactory the system will be extended to the passenger carriages of the company generally.

Bristol.—The Telephone Company recently approached the Sanitary Committee with a scheme for placing the main wires underground throughout the city, and the borough engineer was requested to report on the matter, and to embody in his report particulars of charges imposed on telephone companies by local authorities in other towns. The engineer has reported in favour of the scheme, and says that the charges vary very considerably, from a moderately substantial sum to a merely nominal one. The recent additional outlay by the Town Council of £10,000 involved in extending the private supply mains has been fully justified. Before the extension only 17,420 lamps were supplied; the number now supplied is 28,210, and, in addition, applications have been received for current for 1,200 lamps. The large output of electricity has considerably reduced the cost of production per unit, and, consequently, the Electrical Committee have not recom-

Digitized by Google

mended the provision, in the rate of April, 1896, of any sum beyond the cost of street-lighting, all expenses for the repayment of loans and interest, working expenses, and maintenance of the undertaking being paid out of revenue. The committee want to extend the system, and an estimate has been prepared by the electrical engineer showing that the cost of enlarging the central station, purchasing additional machinery, and extending the mains will amount to the sum of £75,000. By means of this outlay the number of lamps will be increased from 34,000 to 76,000.

Dundee.—The new operation theatre at the Royal Infirmary has been fitted with electric light and electric appliances. The electrical fittings for medical and surgical purposes have been supplied and fitted by Messrs. Mavor and Coulson, of Glasgow, and the current is supplied from the hospital accumulators. In addition to the ordinary galvanic and faradic fittings, a galvano-cautery and a small electromotor for driving a drill by electricity are provided. The whole of the theatre and other rooms have been fitted up with electric light by Lowdon Bros., of Dundee. The large central swing electric light runs on travelling bars, and can be moved to any required position by means of a small windlass A meeting of the Works Committee has been held with reference to a proposal to place the telephone system of Dundee on the twin electric return system, which will necessitate the main routes of wire being placed underground. After a good deal of discussion the principle suggested was generally approved. Mr. Gaine stated that the National Telephone Company would bear the whole cost, and allow the work to be carried out by the Police Commissioners themselves at the sight and to the satisfaction of their own surveyor. With regard to any other consideration to the Corporation, he reminded the meeting that that body already received from the company a consideration equivalent to about £120 per annum in the form of lower rates at which telephonic communication was given to the Lord Provost and several public officials of the city, but notwithstanding that he would recommend the company to give a certain amount from the subscribers whose wires went underground. An adjournment was made in order that the committee should further consider the whole matter and formulate their terms.

Appointments Vacant.—The Corporation of Blackpool invite applications for appointment to the position of resident working electrical engineer to the Corporation. Applicants will be required to undertake the management and control, under the instructions of the Electric Lighting Committee, of the present electricity works of the Corporation, and must be thoroughly competent to design and supervise the construction of all plant, machinery, appliances, and cables necessary for the public and private lighting of the borough, and any necessary extension of such plant, machinery, appliances, and cables, and should have a thorough experience as an electrical engineer to a corporation or company working under parliamentary powers. The gentleman appointed will be required to devote the whole of his time to the service of the Corporation, and will not be allowed to engage in private practice. Canvassing either directly or indirectly by or on behalf of any applicant will be deemed a disqualification Applications, stating salary required, and date when applicant will be at liberty, and accompanied by recent testimonials (not to exceed four in number), endorsed "Electrical Engineer," must be forwarded to Mr. T. Loftos, town clerk, Blackpool, by 27th inst.—The Gas Committee of the county borough of Salford require a switchboard attendant for their central station. Salary 35s. a week. Applicants must have had experience in central-station work on high-tension system. State age and experience, and send copies of three testimonials to the Chairman of the Gas and Electricity Committee, Gas Offices, Blocm-street, Salford, endorsed "Switchboard Attendant," before 5 p.m. on April 29, 1896. Canvassing will disqualify —An assistant is required in the physical department of the City and Guilds Central Technical College, Exhibition-road, S.W., having a practical knowledge of alternating-current working and of the designing of alternators. Salary £100 per annum. Apply in the first instance by letter to Prof. Ayrton.

Cork.—The report of Mr. E. W. Walsh, C.E, engineer to the promoters of the electric tramway scheme, which was read at the last meeting of the Public Works Committee, stated that the promoters contemplated an overhead system, carried on centre poles with brackets in the wide streets, and on side poles with brackets or span wires in the narrow streets; the poles and posts and their position to be subject to the approval of the city engineer, and they might be used as lamp-posts by the Corporation or any lighting company that the Corporation might authorise to use them. The voltage would not exceed 500, which is now the Board of Trade limit, and the whole of the electrical appliances would necessarily be subject to the Board of Trade regulations, which are of a most elaborate character to prevent damage to person or property. The usual height of trolley wires was 18ft. over the surface, which was ample, seeing that a railway bridge was required to be only 16ft. The fire-escapes, in the event of having to pass anywhere that there are span wires, could be run horizontally, as they are in American cities. The promoters would agree to be subject to any reasonable conditions in connection with the rights or interests of the Corporation with regard to the formation and maintenance of main and branch sewers, etc., water, gas, and other mains, by-laws and traffic regulations. They also agreed that the position and levels of the lines in the various streets and roads should have the approval of the city engineer. The report was adopted. At the meeting of the Harbour Board, it was decided that Mr. Ronan, law agent, and Mr. Price, engineer to the Board, should attend before the meeting of the Town Council to watch the interests of the Harbour Board when the application came before the Corporation from the electric tramway company. A special meeting of the Council has since been held to consider the application of the company for authority to construct and maintain tramways which will be worked on the overhead trolley system. After a thorough investigation, a resolution was unanimously passed approving the scheme.

Leeds.—At a meeting of the Highways Committee of the Leeds Corporation the minutes of the Tramways Committee were approved. They included the appointment of Dr. Hopkinson as engineer of the electrical tramway from Kirkstall to Roundhay, terms satisfactory to the committee having been arranged. Dr. Hopkinson will take the full responsibility of the equipment, and he has been instructed to prepare the necessary specifications. Mr. Hewson, the city engineer, has also been instructed to prepare plans for the power station near to Crown Point. It is said that overtures between the Highways Committee and the Sanitary Committee, with the object of securing for the former body early possession of the Crown Point depôt as an electric power station, have reached an advanced stage, and that as much progress as possible is being made with the work of equipping the new electric section and erecting apparatus for generating power as can be expected, considering the delicate character of some of the operations. The *Yorkshire Post* says that the extent to which the trial of electricity as a tramway motor resolved on by the Corporation will affect the telephonic system of the city is likely to be far more serious than most people imagine. It will be remembered that the "mixing-up of currents" between the telephone and the electric tramway wires on Roundhay-road was the subject of a lawsuit. Since then the Board of Trade has made important alterations in its regulations bearing upon the laying down of electric tramways. Apart from these new rules, the National Telephone Company, for the convenience of their subscribers, are said to be willing to transfer a large number of their wires that are now carried on poles to conduits underground. The outlay involved will, of course, be a very serious item Some authorities estimate the cost at from £30,000 to £40,000 On the other hand, the company would avoid the cost of "way-leaves" over buildings and other miscellaneous charges incident to overhead wires, and would prevent interruptions such as brought them and the Roundhay Park line lessees into the law courts. The proposals are before the Highways Committee.

Devonport.—The Devonport Electric Lighting Provisional Order Bill has complied with the Standing Orders of Parliament. The order gives the Mayor and Corporation authority to supply electricity throughout the borough. The Corporation shall not, without the consent of the Board of Trade, place any electric line above ground, except within premises in the sole occupation or control of the Corporation, and except so much of any service line as is necessarily so placed for the purpose of supply. Power is given to the Corporation to purchase or lease lands for the purposes of the order to the extent of five acres; to construct street boxes for the supply of energy. It is provided that within two years the Corporation shall lay down suitable and sufficient distributing mains in Fore-street, Tavistock-street, and Marlborough-street, and in addition shall at any time, after 18 months, lay down distributing mains throughout every other street upon being required to do so. All such mains are to be laid down within six months after any requisition served upon them has become binding upon them, or such further time as may in any case be approved by the Board of Trade. The Corporation shall, upon being required to do so by the owner or occupier of any premises situate within 50 yards from any distributing main, in which they are for the time being required to maintain, or are maintaining, energy for the purposes of general supply to private consumers give a supply for such purposes, and they shall furnish and lay any electric lines that may be necessary for the pupose. The cost of so much of any line as may be laid upon the property of such owner, or in possession of the occupier, and of so much as it may be necessary to lay for a greater distance than 60ft. from the distributing main shall, if the Corporation require, be defrayed by the owner or occupier. The maximum power with which any consumer shall be entitled to be supplied shall be of such amount as he may require not exceeding what may be reasonably anticipated as the maximum consumption on his premises. Whenever the Corporation make default in supplying energy, they shall be liable to a penalty not exceeding 40s. a day Prices charged by the Corporation to any ordinary consumer otherwise than by agreement may be based on the actual amount of energy supplied, or by the electrical quantity contained in the supply, or by such other method as may from time to time be approved by the Board of Trade. When the Corporation charge by the actual amount of energy supplied they shall be entitled to charge at the following rates per quarter: for any amount up to 20 units 13s 4d., and for each unit over 20 units 8d. Power is taken to transfer, if they see fit, the privileges of the order, with the consent of the Board of Trade, to any company or person.

Glasgow.—Councillor Crawford and Mr. Young, who made investigations on the Continent of Europe into the working of mechanical tramway motors for the Corporation, have issued their report They visited Brussels, Hanover, Berlin Dresden, Budapest, Vienna, Milan, Genoa, Paris, and Rouen, and their general conclusions are that the time has arrived when the Corporation should make arrangements for beginning as soon as convenient to work some of the tramways by mechanical traction. The overhead system of electric traction is the best they have seen, and can be made applicable to any part of the city. The Corporation should begin by testing this system on one important route, and as the increasing traffic is sure to require further extensions of the

Digitized by Google

tramway service before next summer, a trial line should be got ready by next spring to save further extension of the present system. In the erection of overhead wires, the cross span wires, they recommended, should be fixed to buildings wherever possible. Hamburg is stated to have the largest installation of electric traction in Europe. At the meeting of the Corporation Mr Primrose, in moving the adoption of the minutes of the Watching and Lighting Committee, called special attention to the report submitted by the joint sub-committee on gas and electric lighting of the streets, which had already been published. The further outcome of this investigation would probably be put before the Council at a later stage. The committee were at present experimenting with a small circuit of the existing lamps, which they proposed to alter for the overhanging lamps. The success or non-success of that experiment would determine the treatment of the remainder of the pillar lights. As members had seen from the report of the deputation on the subject, there was a possibility of electric traction being introduced in connection with the tramways and that might probably lead to the solution of the question of the lighting of the leading thoroughfares by electricity. It was extremely likely that it might be found convenient and profitable to unite street-lighting with the development of traction by electricity. Mr. Primrose rose to propose the following resolution, of which he had given notice: "That it be remitted to the Watching and Lighting Committee to consider whether the present arrangement under which that committee pay the same rate per 1 000 cubic feet of gas consumed in street and stair lighting as the ordinary consumer is an equitable one for the community, and whether means could be devised for the improvement of the general lighting of the city, and report." On a point of order, the Lord Provost said that under the Act of Parliament the Corporation could not carry the motion into effect, even though it was agreed to, whereupon Mr. Primrose said he would readjust his notice of motion.

Lambeth.—At a special meeting of the Vestry, held yesterday week, the question of providing electric lighting for the parish came up. Mr. Stacey Gold introduced a deputation from the Ratepayers' Association asking the Vestry to hand over to a private company the provisional order which it obtained some time ago. After Mr. Gold had answered several questions, Mr. Boyd, on behalf of the Lambeth Municipal Electric Lighting Committee, introduced another deputation asking the Vestry to retain the provisional order in its own hands and to carry out the lighting of the parish itself. The Chairman said he had consulted the clerk, and he was of opinion that the resolution of the Vestry of September 5, 1895, must be rescinded before they could consider the report of the Electric Lighting Committee recommending that the provisional order should be handed over to Mr Sax. Mr. Williams moved, and Mr. Troy seconded, "That the decision arrived at by the Vestry on September 5, 1895, as to the Vestry's electric lighting order may be altered so as to allow the Vestry to adopt the recommendations made in the report of the Electric Lighting Committee dated March 25, 1896, with such modifications thereof as the Vestry, on the consideration of such report, may resolve to adopt, and that any previous resolutions as to the Vestry's electric lighting order contrary to such recommendations and modifications may be revoked." Mr. Alderman Hubbard opposed the motion, and stated that he had never heard any reasons from any of the members of the Electric Lighting Committee as to why the resolution should be rescinded. After discussion, the Vestry voted on the motion to rescind the resolution of September 5, 1895, which ran as follows: "That the clerk be directed to write to the County of London and Brush Provincial Electric Lighting Company and the Capital and Counties Electricity Supply Company, intimating that while not in possession of sufficient information to justify an immediate proceeding under the provisional order obtained, the Vestry have no intention of surrendering the order." This was rescinded by 54 votes to 32 Mr. Williams then moved that the report of the Electric Lighting Committee be adopted by the Vestry. (The report appeared in these columns last week.) Mr. Newton seconded. Mr Prichard moved to refer the report back to the committee. Mr. Everitt seconded the amendment, and after a heated discussion it was rejected by 50 votes to 32. Mr. Hewitt moved, "That the consideration of the matter be adjourned until after the Vestry elections." Mr. Orfner seconded. After further discussion, the Vestry adjourned at 11 p.m., without coming to a decision. We understand that an independent ratepayer has written the Vestry advising that an independent expert should be employed to see that good machinery is installed. It would be well for the Vestry to investigate the independence of the ratepayer, and also the independence of the suggested expert.

Belfast.—At a meeting of the Council in committee the Lord Mayor reported that the special committee appointed by the Council to meet the directors of the Belfast Street Tramways Company, Limited, in reference to the question of electric traction had on the previous day had a conference with those gentlemen, who had, however, placed proposals before the committee which were of such a nature that it was deemed desirable to summon the Council as a whole to consider the matter. The town clerk then read the offer of the tramways company, which contained the following: "The figures which the chairman mentioned to the Lord Mayor this morning as constituting the expenditure of £200,000 which would be entailed by the installation of electric traction, and which the Lord Mayor asked us to put in writing, are as follow: (1) doubling single line (to be authorised by Order in Council), £28,000; (2) doubling single line on Ligoniel and Sydenham lines, £8,250; (3) purchase of these lines, £20,000 (this would give a complete system of 23½ miles); (4) street work for electric traction, 23½ miles, at £2 200), £51,700; (5) power plant, 23½ miles, at £1,050, £24,675; (6) 100 electric motorcars at £500, £50,000; (7) add for widening the existing lines to 6ft, purchase of County Down Railway Tramways, and for contingencies, £17,375. If the term is extended to 21 years the company will be willing to sell the purchased tramways - (1) Sydenham, (2) Ligoniel, (3) County Down Railway—to the Corporation on the same terms as their own, and the company's opposition to the Boundary Bill will, of course, cease. Having regard to the large expenditure of £200,000, the company cannot see their way to the adoption of electric traction unless the term is extended, especially in view of the great doubts explained by the chairman as to how much of the expenditure would come back at the end of the present term in 1907. I think you may assume that if the company's proposal for the extension of the term by seven years is agreed to, the conditions set forth in the report of the deputation of the Corporation would be in the main accepted." After two hours' discussion, Councillor Young moved, and Councillor Curley seconded, "That the Council in committee approve of the recommendation of the special committee to permit the tramways company to get an amended Bill, as may be settled by the town clerk, for the protection of the interests of the city, and with the clause that none of the powers of the Bill are to be exercised without the consent of the Corporation being first obtained." Alderman Henderson moved as an amendment, "That the Belfast Corporation, now in committee, desire to inform the directors of the Belfast Street Tramways Company, Limited, that they decline to accept the offer made to them this day by letter, and also that they will not agree to any extension of the term already held by them." Councillor Harper seconded the amendment, which was carried by eleven votes to six.

Bradford.—At a meeting of the Gas and Electricity Supply Committee the town clerk (Mr. W. T. McGowen) referred to an application which is to be made to the Privy Council by the Westinghouse Electricity Company, Limited, for a renewal of certain patents for distributing the electric current by means of the three or five wire system. The authorities of Bradford, Hull, Glasgow, and Dundee, recently adopted the system, the patent rights for which have been acquired by the Westinghouse Company, who have given notice of their intention to apply for an extension of the expiring patents for a further term of 14 years. The Town Clerk reported that the joint objections of the interested bodies opposing the application had been formulated and duly lodged with the Privy Council, with whom the decision rests. The document contains 10 clauses of objection. In the first place, it is contended that the inventor has already received full and adequate remuneration, or, if he has failed to do so, he has himself to blame. It is also alleged that the invention is not the only method of distributing electricity by a three or five wire system; that the Westinghouse Company acquired the patent, not for the purpose of assisting the inventor, but merely as a trading speculation; and that, even if they have not received adequate remuneration, this is not sufficient ground for the extension sought Further clauses contend that the present holders of the rights have already had full and adequate remuneration for the invention, or, if they had not done so, their failure is due to negligence and refusal to grant licenses on reasonable terms. It is also asserted that if the petitioners had exacted royalties from all users in the same manner as they had exacted from the objectors, they would have realised a very much larger profit than they have made. The objectors state that they paid large sums of money by way of royalty on the understanding that the patent would expire next July, and they contend that the alleged invention is not of such special or exclusive merit or public utility as to be a sufficient justification for any extension of the patent. Mr. Rienzi Walton, one of the inspectors of the Local Government Board, has held an enquiry into the application of the Corporation to borrow £40,000 for the purpose of extending the electricity works The Town Clerk stated that the Corporation were the first public body to adopt electricity as an illuminant. They were compelled to take this step in 1888, in consequence of having received notice from several companies of their intention to apply for powers to enable them to commence operations in the borough. The Corporation felt it was in the public interest that they should have control over any such undertaking An initial expenditure of £20,000 was incurred, and their venture proved to be so satisfactory that in 1890 the works had to be extended at an additional cost of nearly £30,000. In 1893 a further sum of £30,000 was borrowed for extensions, making altogether a total of £80,000, the outlay of which was duly confirmed upon the occasion of each extension by the Local Government Board. Of this amount £74,162 had been actually expended; there were liabilities to the extent of £3,514 leaving a balance of £2,324 to work upon. The Corporation now found it necessary to borrow £40,000, which it was proposed to expend as follows: site, £2.609; buildings, £11,500; condensing reservoir and 200 yards of 12in. iron pipe, £220; machinery, £10,325 (including engines £4,400; dynamos, £2,650; boilers. £3,000; feed pump, £175; weighing machine, £100); steam-pipes, £1,135; condensing plant, £1,500; electric lighting of building, £50; batteries. £750; switchboard, £500; cable, £4,000; travelling crane, £320; and cables for changing mains from two-wire to three-wire system, £7,000. Evidence was given by Mr. A. H. Gibbings (the electrical engineer) in support of the application. He said that in January last the present electric lighting plant was 18 per cent. below the standard requisite to enable the Corporation to adequately deal with the demand, and at the present rate of increase in the requirements, the plant would be 30 per cent. below the demand during the pressure of next winter. No opposition was offered, and the enquiry then closed. Mr. Walton afterwards visited the site of the proposed extensions.

PROVISIONAL PATENTS, 1896.

APRIL 13.

7760. Improvements in double-pole switches for electric lighting. Frederick William Heaton and Harry Smith, Salford Switch Works, Sidney-street, Salford, Manchester.

7789. An improvement in electric arc lamps. James Brockie, 28, Southampton-buildings Chancery lane, London.

7791. Improvements in electric stop-motions for engines. Louis St Peter. 45, Southampton-buildings, Chancery-lane, London. (Complete specification)

7794. Improvements in shade-holders for incandescent electric lamps. Henry Amyatt Chaundy Hellyer. 53, Chancery-lane, London. (Complete specification.)

APRIL 14.

7834. Improvements in underground systems for electric railways. Alvaro S. Krotz, William P. Allen, and Oliver S Kelly. 5, John Dalton street, Manchester. (Complete specification.)

7854. Improved means for regulating electric motors. Otis Elevator Company, Limited, 55, Chancery lane, London. (Otis Bros. and Co , United States.) (Complete specification.)

7881. Improvements in electric current transformers and method of cooling the same. James Devonshire, 70, Chancery-lane, London. (Walter S. Moody, United States) (Complete specification.)

7882. Improvements in regulating alternating-current electric motors of the induction type. James Devonshire, 70, Chancery-lane, London. (William B Potter, United States.) (Complete specification.)

7883. Improvements in regulating alternating-current electric motors James Devonshire 70, Chancery-lane, London (Charles P. Steinmetz and Ernst J. Berg, United States.) (Complete specification)

7884. Improvements in safety devices for alternating electric current power systems James Devonshire, 70, Chancery-lane, London. (Ernst J. Berg, United States.) (Complete specification.)

7885. Improved compound mould for forming incandescent electric lamp bases. James Devonshire, 70, Chancery-lane, London. (Jacob Henry and August Pederquist, United States.) (Complete specification.)

7896. Improvements in electrical haircutters and singers Frank Merril Bell and James Lundie Sloss, 53, Chancery-lane, London. (Complete specification).

APRIL 15.

7928 Electric signal-indicator. Maunsell Mercier, 5, Deansgate, Manchester.

7973. Improvements in electrical accumulators. Albrecht Heil, 28, Southampton-buildings Chancery-lane, London.

APRIL 16.

8062. Improvements relating to electric railways. Percy William Thomas Davies, 322, High Holborn, London

8067. Magneto-electric governing appliance for steam-engines, water-wheels, and such like apparatus. Reginald Page Wilson 70, Chancery-lane, London.

8068. Magneto-electric regulating and controlling appliance for dynamos and other electrical apparatus, adapted also for indicating and recording purposes. Reginald Page Wilson, 70, Chancery-lane, London.

APRIL 17.

8134. A new or improved electrical welding process. Louis Wimmar Breuer, 37 Chancery-lane, London.

8141. Switch apparatus for electromotors with automatic resistance regulator. Siemens Bros. and Co , Limited, 28, Southampton - buildings, Chancery-lane, London. (Siemens and Halske, Germany) (Complete specification.)

8163. A new or improved alarm clock and apparatus for automatically operating electric signals at definite hours Leonhard Mesmer-Weber, Norfolk House, Norfolk-street, London. (Complete specification.)

APRIL 18.

8169. Electric lighter for incandescent gas lamps. Philip Meyer, 89 Chancery-lane. London. (Date applied for under Patents, etc., Act 1883, Section 103, September 20, 1895, being date of application in United States)

8185. An improvement or improvements in the method of raising or lowering electric light fittings, gas fittings, and the like Percy Garniss Ebbutt, Plume Works, Aston, Birmingham.

8208. A new or improved make of housing or troughing for electric wires. John Row, 55, Market-street, Manchester.

8210. Improvements in means for automatically controlling the carbon feed in electric arc lamps. Henry James Fisher, 70, Chancery-lane, London. (Complete specification)

8216. Improvements in electric motors and dynamos. William Edward Gray, 77, Chancery-lane London.

8234. Improvements in prepayment meters for gas or other fluid, or for electricity. Lewis Sayre Burchard, 4, South-street, Finsbury, London. (Wesley Webber, United States.)

8228. Improvements in armatures for electric generators or motors Siemens Bros. and Co , Limited, and Edward Friedrich Heinrich Hermann Lauckert, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

NOTES.

Institution of Electrical Engineers.—There is to be a students' visit to the London Electric Supply Corporation's station at Deptford on May 9. Students desiring to take part in it should communicate with Mr. Allingham.

Berlin Exhibition.—The Association of German Electrical Engineers, in conjunction with the Association of German Engineers and the Electrical Association of Berlin, will have a meeting room for members and visitors at the Berlin Exhibition.

Scots Engineers and Shipbuilders.—We have received a copy of the *Transactions* of the Institute of Engineers and Shipbuilders in Scotland. It contains Mr. Stewart's paper on welded iron and steel pipes and Mr. Beardmore's paper on nickel steel.

Motorcarts.—Lord Harris's Bill on the subject of self-propelled vehicles on roads passed its second reading in the House of Lords last week. The fixing of the maximum weight for electric carriages under the Bill is to be considered, as the two-ton limit is too low.

Personal.—Mr. Walter A. Poynton is about to leave the Electrical Power Storage Company in order to take up the position of assistant engineer at the Hôtel Cecil, now about to be opened, the lighting of which alone involves the installation of generating plant upon a by no means small scale.

Search-Lights at Sea.—Admiral Henry Boys presided on Wednesday at the Royal United Service Institution, Whitehall, when Mr. B. Tower described an apparatus for providing a steady platform at sea for search-lights, etc. We proposed to give Mr. Tower's lecture in full in a future issue.

The City and the Telephone Company.—An application of the National Telephone Company for permission to lay cables under certain thoroughfares in the City was considered at a meeting of the City Commissioners of Sewers last Tuesday, and it was decided to refuse the application, on the ground that the company was not prepared to make any concession for the public benefit in return.

Hydraulic Engines.—In connection with the Society of Engineers Mr. Arthur Rigg is to read a paper at the Royal United Service Institution on May 4 on the subject of hydraulic rotative engines. Mr. Rigg intends to remark on the fact that while great literary attention has been given to turbines, the hydraulic engine has been comparatively neglected and remains without anything equivalent to the care which has been bestowed on improvements in the steam-engine.

Stamping Patent Forms.—Mr. Jackson, M.P., who has been in correspondence with Sir H. Reader Lack, the Comptroller of the Patent Office, with reference to the stamping of patent and other forms at Inland Revenue offices in the provinces, has received a letter informing him that the Board of Inland Revenue have authorised their officers at Leeds to stamp in future any patent, design, and trade-mark forms which may be presented to them by the public for that purpose.

Beryllium.—Judging by suggestions made on the subject, some people lately have been desirous of getting beryllium (glucinum) used in some way in electrical work. Up to the present, its light weight and high conductivity have been mainly insisted upon, but it is now stated that its coefficient of expansion is the same as that of platinum, and therefore it could be used instead of the latter in incandescent lamps. There is, however, the lower melting point of beryllium to consider before that is done.

Telegraph Poles.—In advocating the adoption of Wohl's system of preserving the bases of telegraph poles by socketing them and surrounding them with cement, the *Elektrotechnischer Anzeiger* estimates that the telegraph poles of the whole of the European Continent represent a value of more than £10,000,000, and that the yearly cost of renewals runs up to a million. Any improvement on the existing practice which would give a longer life to the pole must therefore result in an aggregate saving of an anything but inconsiderable amount.

Carriage Manufacturers.—The summer meeting of the Institute of British Carriage Manufacturers has this year been fixed to be held in London. The conference will open on Tuesday, June 23, when the members will be received by the Lord Mayor at the Mansion House, where the president's address will be delivered. In the evening the members will dine at the Holborn Restaurant, and on the third day, by special invitation of the directors of the Crystal Palace Company, the members will visit the International Horse and Horseless Carriage Exhibition.

Direct West Indian Cable.—In the House of Commons last week Mr. Chamberlain, in answer to a question from Mr. Tomlinson, said he had received communications from the West India Colonies, representing the importance of establishing a through telegraph communication between this country and those colonies, for the purpose of Imperial defence, as well as for commercial purposes. He had no reason to think that there are any insuperable difficulties in effecting any such communication, and proposals on the subject were under consideration, which he hoped would result in a cable being laid at no distant date.

Naval Architects.—The summer meetings of the Institution of Naval Architects will be held this year in Hamburg, on Monday, June 8. On Wednesday, June 10, the meetings will be transferred to Berlin, on the invitation of the Imperial German Government, and they will be continued there during the remainder of the week. Particulars of the papers to be read, of the works and places of interest to be visited, and of the excursions and entertainments which are being organised, will be forwarded to the members on or about May 23. The meetings are receiving the warmest support from the Imperial Government, under whose direction the arrangements in Berlin are being prepared.

Cable Interruptions.—From the monthly list of interruptions of telegraph lines given in the *Journal Télégraphique* of April 25 it appears that the Jersey-to-Guernsey cable was interrupted from April 8 to 21. The Gwelo-Salisbury and Beira lines in Rhodesia and Portuguese East Africa failed on April 2, and communications were not restored when the list was compiled. The Aden-Zanzibar cable, which broke down on March 16, was restored on March 22, too late to be included in last month's list. The interruptions of the Brest-St. Pierre cables are now of long standing, as is also the interruption of the Nicaraguan land lines. Other breaksdown were of less than one day's duration.

Cantor Lectures.—On Monday last Mr. James Swinburne gave the first of four lectures on "Applied Electro-Chemistry." At the commencement of his lecture Mr. Swinburne explained that what he said and what he wrote for publication in the Society of Arts *Journal* would be two different things, and that reporters, if any, had best go quietly away. We did not notice that any reporter

Digitized by Google

left, but we quite agree with Mr. Swinburne that what he said was unreportable. The larger part of the lecture consisted in showing simple electrolytic experiments, with a short digression into the mysteries of thermal electricity, and, finally, a comparison of Grottius's views of electrolytic action and the modern views of the travelling of the ions.

The Metric System.—Although the Government have thrown over the committee's recommendation for the adoption of the metric system, the *Times* has published yet a fourth article on the subject, and summed up the whole question in a leader. So that that matter is done with—for the present. There has, however, been an aftermath of letters, including a curious one from Mr. E. Le Clerc. Part of this the *Times* translates and prints in English, part it gives in the original French, apparently because Mr. Le Clerc goes out of the way to be impolite to people that have certainly nothing whatever to do with the matter. This simply excites curiosity as to what might be contained in a third part, which the *Times* apparently judged it undesirable to publish. A letter from Lord Kelvin makes the practical point against a duodecimal division that no one ever asks for thirds of anything. They do not for fifths either, so far as that goes.

Zurich Tramway.—The Centrale Zurichbergbahn is a line about a mile and a half in length with severe gradients, and with curves of as little as 18 yards radius. It is worked on the overhead electric system, but the most noteworthy thing about it is that, instead of a steam plant, the power supply at the generating station is derived from Crossley engines and Dowson gas. The plant is in duplicate—that is, two sets of producers and engines. The latter are about 50 h.p., and are belted to the dynamos. These are four-pole compound-wound Oerlikon machines, and are worked in connection with an accumulator, a supplementary dynamo being provided for charging this. The voltage is 550. The plant has been working about nine months, but no figures are at present available to show whether a superior economy has actually been realised over what could have been obtained by the use of steam-engines. It is, however, understood that the management consider the working and results to be satisfactory.

Carbon Resistances.—The *Elektrotechnischer Anzeiger* of the 12th inst. contains an article on the use of retort carbon as a material for the manufacture of resistances on a principle the patent for which is held by the Vienna Sirius Fabrik. A metre length of carbon of one square millimetre cross-section would give a resistance of about 75 ohms at 0deg. C., with a temperature coefficient of ·00052, its specific resistance being nearly 80 times greater than that of manganese-copper. As an example of apparatus of this kind an illustration and description is given of an adjustable resistance for arc lamps. This consists essentially of a quantity of the best round lamp carbons of the customary length arranged between two slate plates in such a manner as to permit of expansion, and with the necessary connections. The whole is covered with a perforated metal screen. Our contemporary considers that there should be a place for apparatus of this class in alternating-current work, since, owing to the short length required and the avoidance of the coil form, self-induction is obviated.

Iron and Steel Institute.—The following is a list of the papers which will be discussed at the meeting of the Iron and Steel Institute, to take place at the Institution of Civil Engineers on May 7 and 8: "The Rate of Diffusion of Carbon in Iron," by Prof. W. C. Roberts-Austen, C.B., F.R.S.; "Alloys with Iron Carbides," by J. S. de Benneville (Philadelphia); "Mond Gas as applied to Steel-making," by John H. Darby (Brymbo); "Hot-Blast Stoves," by B. J. Hall (Westminster); "The Hardening of Steel," by H. M. Howe (Boston) (adjourned discussion); "The Introduction of Standard Methods of Analysis," by the Baron Hanns Jüptner von Jonstorf (Neuberg, Austria); "The Production of Metallic Bars of Any Section by Extrusion," by Perrey F. Nursey (London); "Mr. Howe's Researches on the Hardening of Steel," by F. Osmond (Paris); "The Treatment of Magnetic Iron Sand," by E. Metcalf Smith (member of the New Zealand House of Representatives); and "The Making of the Middle Lias Ironstone of the Midlands," by E. A. Walford, F.G.S. (Banbury). The Bessemer gold medal for 1896 will be presented to Dr. Hermann Wedding, of Berlin; and the annual dinner of the institute will take place at the Freemasons' Tavern on May 7.

A New Use for Telegraph Poles.—As will be remembered by those of our readers acquainted with the early history of telegraphy, the capture of a criminal through a message sent by the newly-invented apparatus did a good deal towards bringing the telegraph before the authorities. Since then very many gentlemen urgently "wanted" by the police have been secured by its means, so that there is reason to believe that electrical progress has always been regarded with little favour in criminal circles. The final step was thought to be reached when electro cution was adopted in America. The Liverpool police have, however, added another round to the ladder, and at the same time have outrivalled the most elementary prison arrangement described by Mark Twain. Two men were recently discovered in Liverpool while in the act of removing the gas-pipes and internal fittings from some unoccupied buildings. An exciting chase ensued over the roofs of a high warehouse and other buildings. One man was caught and handcuffed to a telegraph post, the two policemen being thus free to chase the other man, who was eventually caught. The remarks of the man as he remained embracing the telegraph post are not recorded, but we understand that they took the form of a petition to the Government on the advantages of underground wires.

The Paralleling of Alternators.—It is sad to note how much the American Press excels that on this side of the water in so far as concerns the superabundant knowledge of its editorial staffs. Up to the present we had thought that both the practical and theoretical knowledge of the parallel running of alternators had its origin on this side of the Atlantic. Our New York contemporary *Electricity* has, however, given publicity to an American development which should, if true, upset all our present arrangements. The editorial statement is as follows: "It is a curious fact, observed in this country but not mentioned in Mr. Hammond's paper, that two alternators coupled in parallel will continue each to contribute its share of current even though the field excitation of one of them is stopped. The E.M.F. will drop somewhat, but they will each continue to do its own proportionate part of the total work, so strong is the tendency of properly constructed alternators to keep in step." These facts are much too deep to admit of ordinary explanation, and we would respectfully suggest either that the properly-constructed alternators had permanent magnetic fields, or else that the "fact" came from the heated brain of a commercial traveller engaged in competition with a rival for a large order. Enlarging on this new departure, we suppose that in a large alternate-current station it will be quite sufficient to excite one alternator only.

Geneva Exhibition.—Writing on the subject of the Swiss exhibition, the *Revue Industrielle* observes that the Swiss engineers will not let slip the opportunity of showing what they can do and of justifying the reputation they

Digitized by Google

have already acquired. Under the auspices of the Swiss Society of Electricians, an international congress will form an occasion for the meeting of all the electrical celebrities of both the New and the Old Worlds, and the discussions between men of science, engineers, and manufacturers, and the excursions made in a country so largely endowed with sources of water power, will hasten the practical solution of the problems attached to the transport and distribution of energy over great distances. But our contemporary adds: "On the programme of questions to be considered at the congress we find neither lighting nor electro-chemistry figure. These are worn-out and somewhat monotonous subjects, although the fight between continuous and alternating currents for the utilisation of power derived from waterfalls might still admit of the presentation of original views both on the theoretical and the commercial side of the question. For the professors both present and future is reserved the supreme pleasure of disserting once more on magnetic and photometric units without coming to any agreement on the subject, but we hope that they will have the politeness, as they did in the United States, to invent another new unit in order to christen it with the name of a Swiss electrician."

Surface Leakage.—The testing of the insulating properties of different materials is usually complicated by leakage round the surface of the article experimented on, and unless this is provided against it necessarily vitiates the results. A novel way of eliminating the leakage current from the current passing through the material has been devised by A. Monell, and is described in *Electric Power*. The insulating material to be tested is wrapped on a brass cylinder 1½in. diameter and 4½in. long, the insulation not reaching quite to the end of the tube. Over the insulation is wound a layer of No. 24 B.W.G. copper wire, forming an envelope 2½in. long over the centre of the insulation. Between this and the two edges of the insulation a few turns of wire are wound on each side. The few turns are spaced so as to be equidistant from the ends of the 2½in. coil and the ends of the insulation. The test is then made by determining the current that flows between the brass tube and the coil of wire with a given voltage. The few turns are connected to the opposite pole to the brass tube, which practically shunts past the galvanometer the surface leakage current. The above method is stated to give most satisfactory results, but we should imagine that care must be taken when investigating the properties of material of comparatively low specific resistance. Then if the difference of potential in the galvanometer terminal is fairly large, the shunting effect of the leakage between the 2½in. coil and the protecting coils would be appreciable.

London Tramways.—In reference to the proposal to amalgamate the London tramway systems, the *Times*, in its City article, says that there can be little doubt that sooner or later electric traction will have to be adopted for London, as it has been for many other cities, especially in the United States. Cars driven electrically occupy less space than horse cars; the streets in which they run are cleaner; speed can, on the average, be greater, and there will, consequently, be less hindrance to other traffic. It is considered that a syndicate would be better able to raise the capital necessary for conversion to electric traction than the present companies, and it is pointed out that so far as concerns the general public "the essential thing is that the opportunity now offered for securing a consolidation of the present chaotic tramway system should be utilised. It does not matter to the public whether the work is done by this syndicate or some other, by the companies or by the County Council itself, but it seems to us that any scheme by which the present piece-meal administration would be perpetuated ought to be rejected." It is added that the syndicate offered to carry out the work of uniting the two systems of lines north and south of the river by a line over Blackfriars Bridge. The benefits which this unification would produce need not be dwelt on, but hitherto there has existed a strong objection to allowing tramways to run over bridges in London, though this is permitted in most other cities of the world. The syndicate, however, would be prepared to put the line down at their own expense experimentally and take it up again whenever ordered to do so without any compensation.

Overhead and Accumulator Traction.—In an electric tramway running into a town the terminal part of the journey may often be through comparatively narrow streets, where the poles and wires of the overhead system would prove inconvenient, or where, for other reasons, their erection may be forbidden by the local authorities. Under these circumstances, an obvious expedient is to finish the journey with accumulators. It, therefore, becomes desirable to work out the most rapid and convenient method of effecting the transition from the wire to the battery, and for replacing the latter when exhausted. This is a matter which is very closely connected with the position the accumulator occupies on the tramcar. A usual place for the cells has been under the seats. This has the advantage of keeping the weight low down, but is clearly unsuitable for the present purpose. A plan has been worked in Germany by which the charged accumulators run on small trucks, and are shunted on to the track and attached to the cars where the overhead wire ends. Another system is now described in the *Elektrotechnischer Anzeiger*, in which the cells are placed on the roof of the tramcar. One end goes at once to the base of the trolley arm, and the only other connection necessary is a conductor from the negative terminal to the other side of the motor. The cells are charged on what may be called the first floor of the substation building, and run out of a window at the level of the roof of the tramcar. Inside the building a turntable and sets of rails form a convenient means of getting the cells to suitable positions for charging them.

Acetylene and Copper.—On the subject of the possibility of acetylene forming an explosive compound on contact with copper or brass fittings, the *Revue Industrielle* says that the fear of copper acetylide is the beginning of safety, but as a matter of fact the above-named explosive compound does not occur as easily as has been supposed. Our contemporary considers that there is reason to believe that the true explanation is that the presence of at any rate a small quantity of ammonia is necessary to obtain the formation of the acetylide. The composition and properties of acetylene occupied a great part of Prof. Dewar's last week's lecture at the Royal Institution. It was, he remarked, a very explosive gas, "going off" at a much lower ignition point than coal-gas when mixed with a little air, and, what is more remarkable, it would often explode on its own account (without air) if submitted to shock or concussion. Still, with care it can be used safely enough. Another of its characteristics was that at 83deg. C. below zero it turned straight from gas into a sort of paraffin wax, without troubling to pass through the intermediary liquid stage, but the solid could be subsequently liquefied by heating under pressure. Referring to the use of the electric furnace, Prof. Dewar remarked that it had enabled us to complete the synthesis of the organic chemical compounds. From the carbides, prepared in the electric furnace, we can get benzine (and therefore all the aniline dyes), and even crude petroleum. Again, acetylene combines directly with nitrogen in the

Digitized by Google

presence of an electric discharge, and gives prussic acid. From this we can easily get cyanides, which, treated red hot with steam, yield ammonia. In fact, the chemist sees no end to the sphere of usefulness of the electric furnace, which may even solve the problem of making nitrogenous manures.

The Purchase of the Telegraphs.—The quarrel as to the proper way of bringing into account the interest on the money spent on purchasing the telegraphs still goes steadily on, and seems likely to last until the Government has to purchase the telephones also. In the House of Commons on Tuesday Mr. Henniker Heaton asked the Secretary to the Treasury whether, in regard to the telegraph debt of £10,130,000 and the suggestion to pay it off, his attention had been called to the statement made on page 37 of the forty-first annual report of the Postmaster-General for 1895, that during the year ended March 31 last the expenditure exceeded the revenue by about £154,000, to which must be added the interest (£298,000) on the capital expenditure incurred at the transfer, making the total loss for the year about £452,000; that in the period of 25 years since 1870 the receipts showed a balance of about £1,795,000 in excess of the expenditure, but that they fell short of meeting the interest on capital, the aggregate deficiency in this respect being £5,859,000. In reply to this Mr. Hanbury said the corrected figures gave an excess of expenditure over revenue in the year to March 31, 1895—not March last—of £141,637. 12s. 7d. The Post Office was not aware that any proportion of the moneys applied to the reduction of the National Debt had been ear-marked as a fund for paying off the stock created for the purchase of the telegraphs. Any separate and specific treatment of the telegraph capital would, it is feared, have resulted in its being increased rather than reduced. In a sense the working of the telegraphs had itself hindered the reduction of the National Debt, for it had added to it more than £10,000,000. If, therefore, a strict balance-sheet of the working of the telegraphs was prepared the outstanding debt would not be between 10 and 11 millions, but would be about 16 millions.

Telephoning to Trains.—Some experiments recently tried by Mr. K. L. Martin, assistant engineer on the New York and Brooklyn Bridge, in the way of establishing telephonic communication between moving trains, and between trains and the train dispatcher's and bridge offices, have been described in the *Scientific American*. The necessity of some adequate method of train communication and signalling in cases of fog or some emergency has been felt on the bridge, but there have been difficulties in the way of establishing telephonic communication with moving trains that have prevented it from being put into practice, but which it appears have now been overcome, so that it is now possible to communicate with moving trains with almost the same facility as between fixed points. The Brooklyn Bridge is provided with a trolley wire for electrically lighting the trains. This wire, which was used in the telephone experiment, was connected with the train dispatcher's office and with the bridge offices, and upon the cars were placed arms provided with compound brushes which touched the trolley wire. The circuit was completed through the car truck and track rail, the connection between the circuit wires and truck being completed by a brush resting on one of the car wheels. The compound brush consisted of a number of brushes of brush copper fastened together with intermediate pieces of soft rubber. The brushes being electrically connected with each other and with the telephone wire, arranged in this way, unbroken onversations could be carried on while the trains moved along. It is stated that the electrical contact of the compound brush with the trolley wire was so perfect that the sliding of the brush on the wire produced no noticeable effect. It is proposed to permanently equip the cars with telephones and to provide a suitable electric conductor on the bridge in convenient position for contact with the brushes carried by the cars.

The Nature of Electrolysis.—If, for instance, potassium and chlorine are brought together and unite, a very large amount of energy is given off, and it may be accepted that they cannot afterwards be separated without the expenditure of an equal amount of energy to that which was produced by their combination. Nevertheless, according to recent theories of the nature of electrolysis based on the discoveries of Arrhenius and Van t'Hoff, when potassium chloride is dissolved in water its molecules (or at least a proportion of them) are dissociated, not merely into potassium and chlorine molecules, but into actual atoms. It therefore becomes necessary to explain how the energy for this process is obtained. In the course of a paper, mainly historical in character, read by Dr. J. W. Richards at the Franklin Institute, Philadelphia, the suggestion is made that the atoms are really united by as great a force after dissociation as before, only it is electrical "force" instead of chemical "force," and as chemical "energy has been replaced by electrical energy, it is a case of conversion of energy," and therefore no additional energy need be supplied for the process. What follows, however, is by no means so clear—namely, that "since the atoms are no longer held together by the force of chemical affinity, they will be free to act as if chemically independent of each other—*i.e.*, as independent atoms." (This is necessary to explain the properties of the solution.) And also, since the atoms are "held together by electrical instead of chemical energy, they are susceptible of being separated by a counter electric force." The anomalous use of the words "force" and "energy" being allowed for, this may, or may not, be a statement of what really occurs, but in spite of a mechanical analogy given by Dr. Richards it is a little difficult to form a mental picture of the precise change that is assumed to take place. Indeed, until there is some clear theory as to the nature and difference between the electrical attraction of the atoms and chemical affinity—if, indeed, they are not parts of the same thing—an explanation of this character may very easily degenerate into a mere play on words.

Fenders and Brakes.—The Americans have had much more experience than we have in England in the matter of running electric tramcars, but they have by no means settled all the problems connected with it. On this subject *Electrical Industries* remarks that in the United States "the fender, although by some city governments the company is forced to furnish them on cars, has never been popular with the companies, and will probably never become universal. It is but a modification of the 'cow-catcher' of the steam locomotive, whose duty it is to throw the cow from the track regardless of what injuries the cow may receive. Inventors have placed springs and cushions of all kinds on frameworks of curious designs with the idea that the victim would be carefully picked up and held as gently as an infant in its mother's arms, no matter at what speed the car might be going, or in what position he might be in when the car reached him. Some railway managers have wisely grasped the situation, and have watched the improvement in car brakes as a solution of this problem. On the old horse-cars hand-brakes were satisfactory, and met all requirements of the service. They passed out of date however, with the street-car horse, and have on modern cars been a constant reminder of that antiquated method of transportation. Steam roads long ago discarded hand-

Digitized by Google

brakes for their passenger trains, and the freight cars are now being rapidly equipped with the more efficient and serviceable air-brake. The enterprising manufacturer has adapted this form of brake to the service of the street car, both electric and cable. Their works are now busy filling orders for the progressive railway companies, who see in this form of brake a remedy for many of the defects of the present railway system. A less number of accidents, faster time, more efficient service, and an entire equipment corresponding to the progressive age in which we live are some of the advantages of this type of brake for street railway cars." As to this, any mechanical brake is doubtless better than a hand-brake, in so far as it is more powerful and quicker in action, but the great advantage of the "air-brake" on a railway train is that it affords a means of braking all the carriages from any one of them, but it does not follow that this form of brake will retain its superiority when applied to cars which only run singly, as tramcars do.

Rontgen Radiations. — Although, unfortunately, much valuable time and trouble has been wasted by experimenters simply duplicating each others' work, additional knowledge is gradually being acquired as to the nature and properties of the new radiations. From the American technical Press it appears that Prof. O. N. Rood, of Columbia University, New York, has succeeded in reflecting Röntgen rays from a surface of platinum foil at angular incidences, but even at 45deg. only about $\frac{1}{2}\frac{1}{5}\frac{1}{0}$th, so nearly as can be judged, is reflected. Hitherto reflection has only been obtained at practically grazing incidences. This is hardly the place to go into questions of molecular constitution, but it would be interesting to know whether any results can be obtained in this way with mercury or even lead. In reference to the theory of the matter, nothing comes forward in support of the longitudinal hypothesis, and there is already some, though not much, direct evidence against it. It will be remembered that radiations obtained from the fluorescence of potassium uranyl salts have most, if not all, of the properties of the Röntgen rays. It now appears that these radiations can be polarised by tourmaline with all the usual phenomena, which at once establishes the transverse character of the vibrations and shows that vibrations of that character are capable of doing all that is necessary to explain the phenomena observed. The direct evidence in favour of the longitudinal wave has hitherto been confined to some rather fine-drawn conclusions derived from a comparison between the action of the Röntgen radiations and ultra-violet light in discharging a condenser or electroscope. The argument never seemed to us to have any weight whatever, but anyhow it has been destroyed altogether by an observation of Prof. Röntgen himself, who, it appears, as the result of most careful experiments, has ascertained that at any rate a gaseous dielectric remains "leaky" for an appreciable time after the action of the radiations on it has ceased. The effect, therefore, is a molecular one in the dielectric, and can have no special direction quality. It looks very like a case of quasi-dissociation, and may some day throw light upon the very vexed questions of electrolysis and gaseous discharge. Lastly, it has been objected against any wave theory that it is impossible to get interference fringes with the new rays. It has now been ascertained that as the exhaustion of the vacuum tube is increased the character of the radiations greatly changes, so that, for instance, from the same tube at different exhaustions radiations may be obtained to which bone is respectively transparent and opaque. This shows that the radiations are far from being homogeneous. Now with ordinary light, the range of which is well inside one octave, the fringes are a colour rather than an intensity effect, and their number is strictly limited. If, therefore, the Röntgen rays are made up of undulations of widely differing wave-lengths, any attempt to get interference phenomena will be exceedingly difficult, not to say hopeless, until there is some means of separating out what are practically "monochromatic" radiations.

Thermo-Electric E.M.F.—In a thermo-electric circuit in which one of the junctions is at a temperature of h and the other at a temperature of c degrees on the ordinary centigrade scale, the E.M.F. in the circuit due to the difference of temperature is a function of h and c, which, whatever its form may be, will involve constants depending upon the nature of the metals. The discovery of the form of this function is not only a matter of scientific interest, but is needed for such a practical matter as the satisfactory calibration of a pyrometer. About five empirical forms have been proposed. The first is a series of ascending powers of the absolute temperature with arbitrary coefficients, one of the junctions being assumed at zero. For the two temperatures the difference of the series is used, and the terms are of the form $N(h^n - c^n)$, h and c being, of course, absolute and not centigrade temperatures. As a matter of fact, however, only two terms are used, and as there is obviously no constant term the expression becomes a simple parabolic one. Avenarius, Thomson, and Tait have proposed forms involving essentially products of the sum and difference of the temperatures with the addition of constants, and which therefore reduce to the same thing. The Barus formula is an exponential one. In the issue of the *Proceedings* of the American Academy an account is published of the work done on this subject by Mr. S. W. Holman in connection with the Rumford fund. Mr. Holman has been endeavouring to find a formula which will give more correct results than any of the above. In passing, he remarks that "there seems to be little hope of arriving at a close approximation to the natural law except through an expression which shall contain separate terms representing the temperature function of the component arising at the contact of the dissimilar metals and that arising from the inequality of temperature at the ends of each (homogeneous) element (the Thomson effect)." The parabolic formula would comply with this if the contact E.M.F. varied as the first power and the Thomson E.M.F. as the square of the temperature, but in that case the neutral point would have an explanation different from that usually accorded to it. Mr. Holman, however, proposes for practical work to represent the difference of the E.M.F.'s of the hot and cold junctions by the difference of powers (not integral ones) of the temperatures in each case multiplied by a constant. As the cold junction is usually kept at one temperature—*i.e.*, 273deg. absolute or 0deg. centigrade—the expression for the E.M.F. reduces to $m\,t^n - b$, where t is the absolute temperature of the hot junction and m, n, and b are constants. Mr. Holman does not advance this expression as a possible natural form of the function, but states that it very closely fits the experimental data. That it should do so follows from the known adaptability of the exponential equation to represent limited portions of any curved line. On the basis of this formula, Mr. Holman proceeds to work out interpolation and extrapolation formulæ for graduating a pyrometer, which lead in the case of a Le Chatelier pyrometer to a logarithmic instead of a direct plot. He also shows that his formula gives results more in accordance with known data than any of the others at present in use. He, however, advocates the establishment of a standard based on the melting points of inexpensive metals, with a possible system of simple alloys to give points of sufficient frequency as pyrometric "bench marks."

LECTURE XXIX.

(Specially Contributed.)

How to Obtain the Best Effect.—Faraday in his first apparatus supplied the most efficient form of machine that could be devised. All our modern investigations have not led us to find a flaw in its perfectness so far as form is concerned. Unfortunately, for many purposes, in practice this apparatus can only be used in a secondary sense. By it we cannot transform other energy into electrical energy. Its use is, when we have obtained electrical energy by other means, to harness that energy so as to utilise it for a particular purpose. An examination, however, of this practically almost perfect machine will assist us in determining the gradual progress of the various types of machines towards economy from the time of Faraday till the present day. Not only does Faraday's apparatus give the best effect, but it gives us

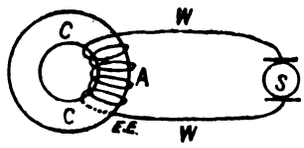

FIG. 1.

the means of measuring that effect. In Fig. 1, suppose S represents a source of electricity, W W all the wire connections carrying current to the coil, A, while C C is a complete ring of iron forming the core of the coil A. We have seen that when a current is passed through the coil magnetic lines of force are formed in the core. The number of such lines is indicated by the formula $L = \frac{P}{R}$. Now P depends on the current through the coils and the number of turns in the coil. We can easily measure the current through the coil by putting an ammeter, G, in that circuit, as in Fig. 2.

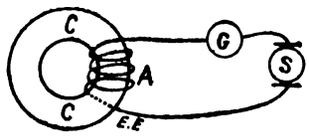

FIG. 2.

Suppose a current of one ampere is shown on the ammeter, then a current of one ampere goes through each turn of the coil, and by counting the number of turns we know the number of ampere-turns. The ampere-turn is, as we have seen, taken as the unit of magneto-motive force, then the number, n, of ampere-turns measures the total magneto-motive force, or magnetic pressure used to generate the lines of force

It is fairly easy then to obtain a constant magneto-motive force.

It is not so easy to obtain a fairly constant magnetic resistance.

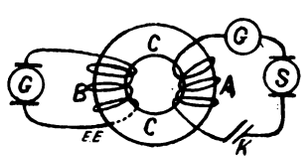

FIG. 3.

It is fairly easy to compare magnetic resistances. Upon the core, C (Fig. 3), wind another coil, B, and connect preferably to a ballistic galvanometer, G_1. Call the coil A the primary coil, and the coil B the secondary coil. In the circuit of the primary coil put a key, K, to make and break the circuit. In such experiments as these the best source, S, is perhaps a good secondary battery.

Make the primary circuit and note reading of ammeter, G. There is induced in the secondary circuit a current whose value is shown by the deflection of the galvanometer, G_1.

Now change the core, C C, for iron of another kind or of another maker, and repeat the experiment, keeping current through primary the same as before.

The result will probably be a different reading of G_1, showing either a greater number of lines of force loop round the secondary coil—that is, go through the new core—or a less number.

If you take half a dozen different makes of iron, fashion them as nearly as possible into cores of similar length and sectional area, it will be found that each core differs somewhat in magnetic resistance to the other cores.

Hence, the core increases or decreases in **permeability** - that is, to the property of stopping or passing through lines of force—and this greater or less permeability depends upon the **reluctance**, or resistance, of the core. The greater the reluctance the less the permeability, and the less the reluctance the greater the permeability. The properties are, therefore, in inverse ratio to each other, but the whole thing is the same as saying, the greater the resistance the less the number of lines of force, and the less the resistance the greater the number. I am old-fashioned enough to prefer the common everyday words, that clearly explain themselves to any of the new-fangled words, which are not introduced to simplify, but to obscure. To resume:

If the primary and secondary circuits were alike as to the number of turns in coils, to resistance, etc., then G_1 would momentarily indicate like G—if *all* the lines of force took the path of the core; but they don't. The iron core path is the path of least resistance, but there are other paths, and some of the lines—not many in the case of a complete ring of the best iron—do leak and have no effect, or an adverse effect, on the secondary coil or on galvanometer, G_1.

The galvanometer, G_1, allows us to measure the effect of *all* the lines that loop coil B.

To continue our experiments. Take any one of the cores, C C.

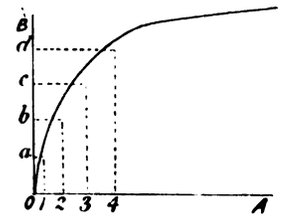

FIG. 4.

1. Let a current of one ampere go through primary, and note effect on G_1.
2. Let a current of two amperes go through primary, and note effect on G_1.
3. Let a current of three amperes go through primary, and note effect on G_1.

And so on.

We can show the effect by means of a diagram, Fig. 4.

Let O A represent the magnetic pressure;
„ O B represent the lines of force evoked by the pressure.

We find that at first the number of lines increase almost in proportion to the pressure—that is, if we double the pressure (ampere-turns) the number of lines of force are double. Thus, 20 ampere-turns give double the effect of 10 ampere-turns.

By increasing the pressure we soon find that the number of lines do not increase proportionally, and increasing the pressure still further, we find that the additional increase hardly alters the number of lines. This result goes far to prove my contention previously expressed, that *each line of force* (by this, of course, I mean the phenomenon we have agreed to represent by a line) *occupies space* to the exclusion of any other line of force from that space. Thus, when the space—that is, the sectional area of the iron—contains no lines the number evoked is proportional for small pressures. When, however, the space is full, increasing the pressure will not, it cannot, put more lines into that space. The point when increased pressure does not increase the number of lines is termed the *point*

Digitized by Google

of saturation of the iron. If we select as a unit for measurement one line per square centimetre, this will give us 6·45 lines per square inch, because one square inch = 6·45 square centimetres. Prof. Ewing, F.R.S., has forced 45,300 lines per square centimetre, or 292,185 per square inch, through iron, but only under exceptional circumstances. Usually, 16,000 to 20,000 lines per square centimetre—that is, 103,200 to 129,000 per square inch—is the value mostly used in the construction of dynamos.

Now, whatever be the number of lines looped through a coil, we know by the indications of our galvanometer they have a twofold effect—one effect on being looped through the coil; an equal and opposite effect on being unlooped through the coil. These two effects have always to be considered when discussing the effects of lines of force upon conductors.

Thus when we close the circuit (Fig. 3) we get an indication on the galvanometer, G_1—that is, the needle swings through a certain number of divisions of the scale. If we keep the key, K, depressed—that is, if we keep the primary circuit closed—the needle of the galvanometer in the secondary circuit will return to zero. If, now, we break the primary circuit, the needle of G_1 will indicate a current of equal strength but in the opposite direction to that indicated on making the circuit.

Now to continue our experiments, but this time with cores not iron. Try cores of the same dimensions as those of iron, but constructed of wood, ivory, paper, glass, etc. On making the primary circuit we shall find an indication of current in the secondary, and this indication will be almost the same whether we use wood, ivory, paper, glass, or nothing at all except air. The indication in G_1 is, however, very small compared to what it was when the iron ring formed the core. In other words, the resistance of the path through the secondary coil has been largely increased, and the number of lines looped around it correspondingly diminished. Iron, as I have said, is our best and nearly our only magnetic conductor. Cobalt and nickel are the other magnetic conductors, though far inferior to iron. If a little manganese be mixed or alloyed with iron, we get a material almost non-magnetic. Iron, then, usually forms the core upon which we wind the coils of the secondary to be acted upon by the lines of force.

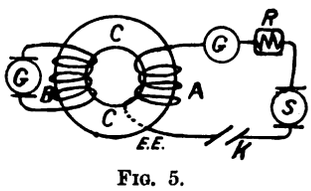

Fig. 5.

There are two more sets of experiments to examine. Into the primary circuit we put this box of resistances, R, Fig. 5. The resistances are so arranged that by adding them to the resistance of the rest of the circuit the total resistance will be about doubled.

1. Make circuit with no extra resistance in, and note deflection of G_1.
2. Break circuit with no extra resistance in, and note deflection of G_1.

Deflection of G_1 is found in No. 2 case to be equal and opposite to No. 1.

3. Repeat No. 1, keep key down, and let needle of G_1 come to rest.
4. Put extra resistance into primary circuit and note G_1.

Deflection of G_1 will be about half what it was in No. 2, but in the same direction as No. 2. Let G_1 come to rest.

5. Break primary circuit by key. Note G_1.

Deflection of G_1 is about same and in same direction as No. 4.

The sum of deflections No. 4 + No. 5 will equal deflection No. 2.

This shows that the total effect of taking out lines of force will be the same whether they are all taken out at once or at separate times. Thus, supposing No. 3 caused a looping through secondary coil of 10,000 lines, experiment No. 4 gets rid of 5,000 lines with a certain result, and experiment No. 5 gets rid of the other 5,000 with a similar result; the sum of the two results is the same as if the 10,000 lines had been taken out at once.

For my second series of experiments I must slightly modify Faraday's ring. C C, the core of coil, B, Fig. 6, is made up of a number of similar half rings of soft iron, and I can take one or more or all those half rings away as I please. Taking them away one at a time I increase and increase the resistance of the magnetic circuit till, when all are gone, the resistance is of air only across the poles of the primary.

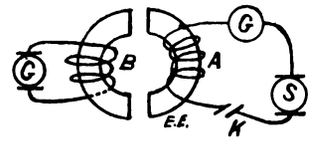

Fig. 6.

1. If now I make the primary circuit, I get a deflection on G_1.
2. Break the circuit; I get an equal and opposite deflection on G_1.
3. Take out all the secondary iron core, and make primary circuit again. We now get a deflection on G_1.

The deflection G_1 No. 1 and G_1 No. 3 are very different, that in No. 1 being the larger.

4. Insert half the core of B, and make primary circuit again. We get another deflection on G_1.

The deflection G_1 in 4 is greater than in 3 and less than in 1.

5. Insert more of the core of B—now making it three-quarters of core—and repeat operation.

Deflection on G_1 is greater than on 4, still less than on 1. In fact, the difference in the deflection of G_1 in experiments 1 and 3 gives us a clue to the value of the iron core in reducing the magnetic resistance.

In both these sets of experiments we can show that the sum of certain arithmetical values of driblets is equal to the arithmetical value not in driblets; but what I want to impress upon you is the fact that although we may arithmetically tot up the same total, the practical result of the two totals is another question.

A thousand or a million boys may shoot peas from pea-shooters at a fortification during the course of 20 years and make no impression, when an 80-ton gun loaded with shell might at one effort blow the whole thing to smithereens.

The best effect to be obtained by the action of lines of force upon a conductor is to loop all the lines of force at one and the same time around the conductor, or to unloop them all at the same time from around the conductor.

This is just what Pixii did not do. He put his lines of force through his coils in driblets, and took them out again in driblets; hence the inefficiency of his machine. It is easy now to see how Pixii might have improved his machine; but it had other weaknesses besides the time it took in magnetising and demagnetising his armature core, only one of which it is necessary to trouble about—viz., that a permanent magnet always gives a weaker field than an electromagnet. If, then, current effects are due to number of lines of force, it is easy to see the larger the number in a given area—that is, the stronger the field—the better is the result.

The Field in Practical Work.—It has been stated that the aim of electrical apparatus is the transformation of energy of another kind into electrical energy, and that the ring apparatus of Faraday was not suited for this purpose. We want to generate a magnetic field in a medium into which we can bring and also take away the conductors upon which the field is to act, or, what comes to the same thing, instead of bringing conductors to the field in which we can take the field to the conductors. The ordinary scholastic view, that the magnetic field of a magnet is illimitable in extent, is incorrect. Practically the area of any particular field is comparatively small, and is absolutely limited. It is as certain as anything well can be that what we represent by lines of force constitute closed curves. There is no such thing in magnetism as an

Digitized by Google

unclosed curve Now, magneto-motive force, of whatever magnitude you like to take, is powerless to form these curves, or force lines—or flux curves—through more than a certain resistance; hence the longest curve line of force is that which is formed when the pressure just overcomes the resistance—and there is none after this. For practical purposes, we limit the area of the field as much as possible and obtain the greatest density of lines in that area. For the purposes of calculation, we may take as the unit of magnetic resistance the magnetic resistance between the faces of a cube of air, the length of the side of the cube being one centimetre. In many—I think in most—calculations an inch cube would be better than a centimetre cube, but the former is appropriated by science. I would like to call this unit resistance a *resistant*—the Americans call it an oersted. Englishmen have not yet agreed what to call it; therefore as we can do very well without the name, the symbol R will answer all purposes. Similarly, I might call unit P the *pressant*, and the unit L the *lineant*. The magnetic resistance of iron varies considerably. For purposes of calculation we may take it as 500 times less than that of air. Thus the magnetic resistance between the two opposite faces of a centimetre cube of iron, or an inch cube of iron, is 500 times less than that between the opposite faces of similar cubes of air. If, then (Fig. 1), the core, C, is a continuous ring, say, with an axial length of 12in., its magnetic resistance is that due wholly to the iron. Suppose, further, the sectional area to be a square inch, and that 100,000 lines are generated by the magneto-motive force used. A similar magnetic circuit, if composed of air, would have a resistance 500 times as great, and the lines of force through it would be $\frac{100,000}{500} = 200$. Suppose I cut the core, C, Fig. 7, and have an air-gap, G, of 1in.

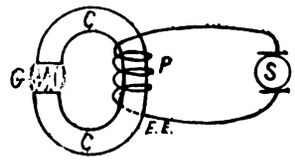

FIG. 7.

length. This air-gap has a resistance of equal to 500in. of iron, so that the total resistance is now equal to 512in. of iron, or $\frac{512}{12} = 42{\cdot}6$ times what it was before. With the same pressure, instead of 100,000 lines, we shall now get $\frac{100,000}{42{\cdot}6} = 2,350$, nearly.

In actual practice the resistance is not increased quite so much as this, because the lines of force spread out and the sectional area of the air-gap field is greater than the sectional area of the iron core, but this increase of area leads to less density of field over the area. The introduction of an air-space into a magnetic circuit is thus seen to be a disadvantage, but we cannot avoid it in the construction of our apparatus.

THE COST OF WORKING POWER STATIONS IN AMERICA.

The adjoined table gives the cost of working 20 different power plants in America for the past six months. The table was prepared by the *Street Railway Review*, and certainly presents an interesting and valuable study, notwithstanding the many unavoidable blanks. Reports 6 and 14 are from plants with mechanical stokers. Among the best reports is No. 19. It shows the best evaporation on the list (it has forced draught and economisers in the stack), and in spite of the high price of fuel comes out with a total cost of power comparing favourably with many plants where fuel is cheaper, and this, too, without excessive fixed charges. The great economy of condensing is in all cases apparent. The most striking differences are in the water evaporated per pound of coal. Even allowing for the differences in coal, there are still great varia-

tions, part of which, no doubt, can be accounted for by wet steam and errors in water-meters. Where the water consumption of the engine is low, however, there is no probability of wet steam. Allowing for all errors, it is not too much to say that there is more chance for improvement in methods of burning coal than in any other step in the transformation of the energy between coal pile and line. Considering the great gain in economy made by condensing engines, it is strange that more attention has not been given in the past to means for providing water for condensing where the station is not situated on a natural body of water. This saving will pay interest on a good-sized investment, and make it worth while to investigate very closely the methods which have been used for cooling and using over and over again the same condensing water.

THE ELECTRIC LIGHTING OF THE HOTEL CECIL.

Through the courtesy of the management, we are enabled to give some particulars of the electric lighting of the huge building which has been for some years in the process of erection on the sites of Salisbury, and Cecil streets. When everything is complete the Hôtel Cecil will contain more than 15,000 incandescent lamps, most of which are 16 c.p. The aggregate length of wiring is reckoned by miles, so that, although a private installation, the work is one which, so far as magnitude is concerned, comes within the dimensions of undertakings for public supply. The hotel is to be opened on May 6, and on visiting it this week all departments were working at high pressure to get everything ready and complete by that date. Much necessarily remains to be done at the last moment, and there is very little time to spare, so that it becomes an act of the barest justice to begin with an acknowledgment of the courtesy of Mr. W. R. Beckton, the resident engineer, in trenching upon his valuable time to give us facilities for obtaining information as to the work that has been done. The Hôtel Cecil consists at present of three blocks—the southern, western, and eastern—of which the eastern is considerably the largest. These are arranged round a central courtyard. A fourth block—the north—facing the Strand, will complete the quadrangle, but the area of this was not included in the original site, and parliamentary powers had to be obtained for its acquisition. Though the matter is practically settled, the final formalities are not even yet complete. The grand entrance and restaurant, which are to face a widened and improved Strand, therefore exist at present only on paper, and the area is at present occupied by ordinary shops, which entirely mask the grand proportions of the buildings.

Leaving the history of the undertaking, it will be sufficient to say that the property is now owned by a limited company, of which Viscount Hardinge is the chairman. The site of the building is a somewhat severe slope from the Strand to the riverside, and consequently on turning into what seems an entrance roadway and a long courtyard on a level with the Strand, the visitor has really a very great deal more building work beneath his feet than he would be likely to imagine. It is naturally in this part of the hotel that space has been found for the boilers and machinery of the generating plant. As a matter of fact, these are placed in the arches which carry the basement floor of the western block. It is probable that it was not originally intended to provide a generating plant at all, but to take current from the Charing Cross and Strand Company, whose station is in the immediate neighbourhood. In reference, therefore, to the type of the machinery installed, it must be remembered that the space in which it was to go had to be considered as well as the output that would be required from it. This,

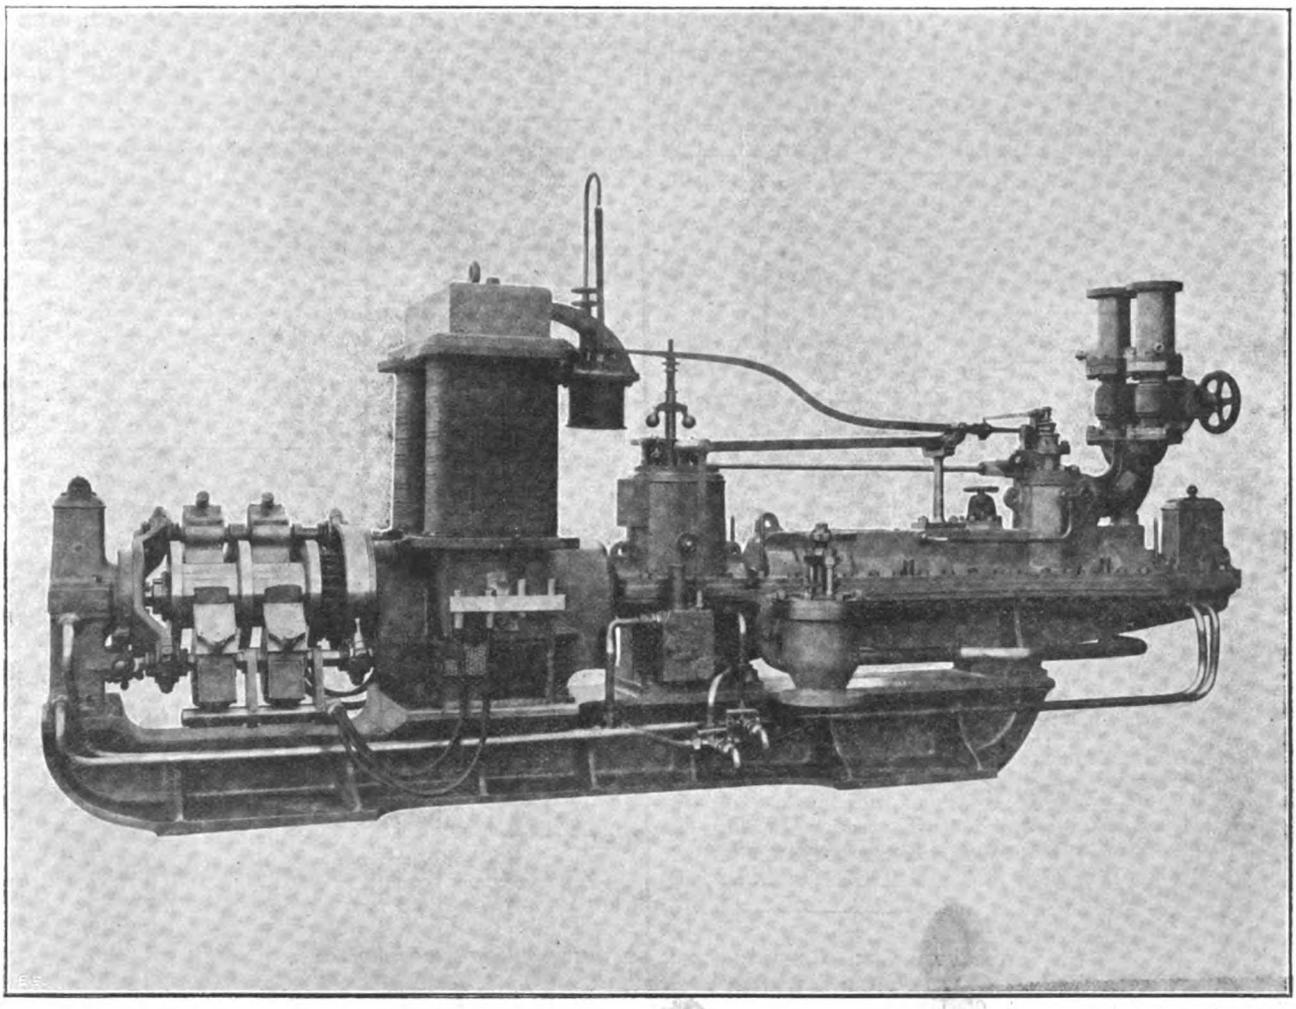

FIG. 1.—View of Parson's 75-K.W. Steam Turbine and Dynamo.

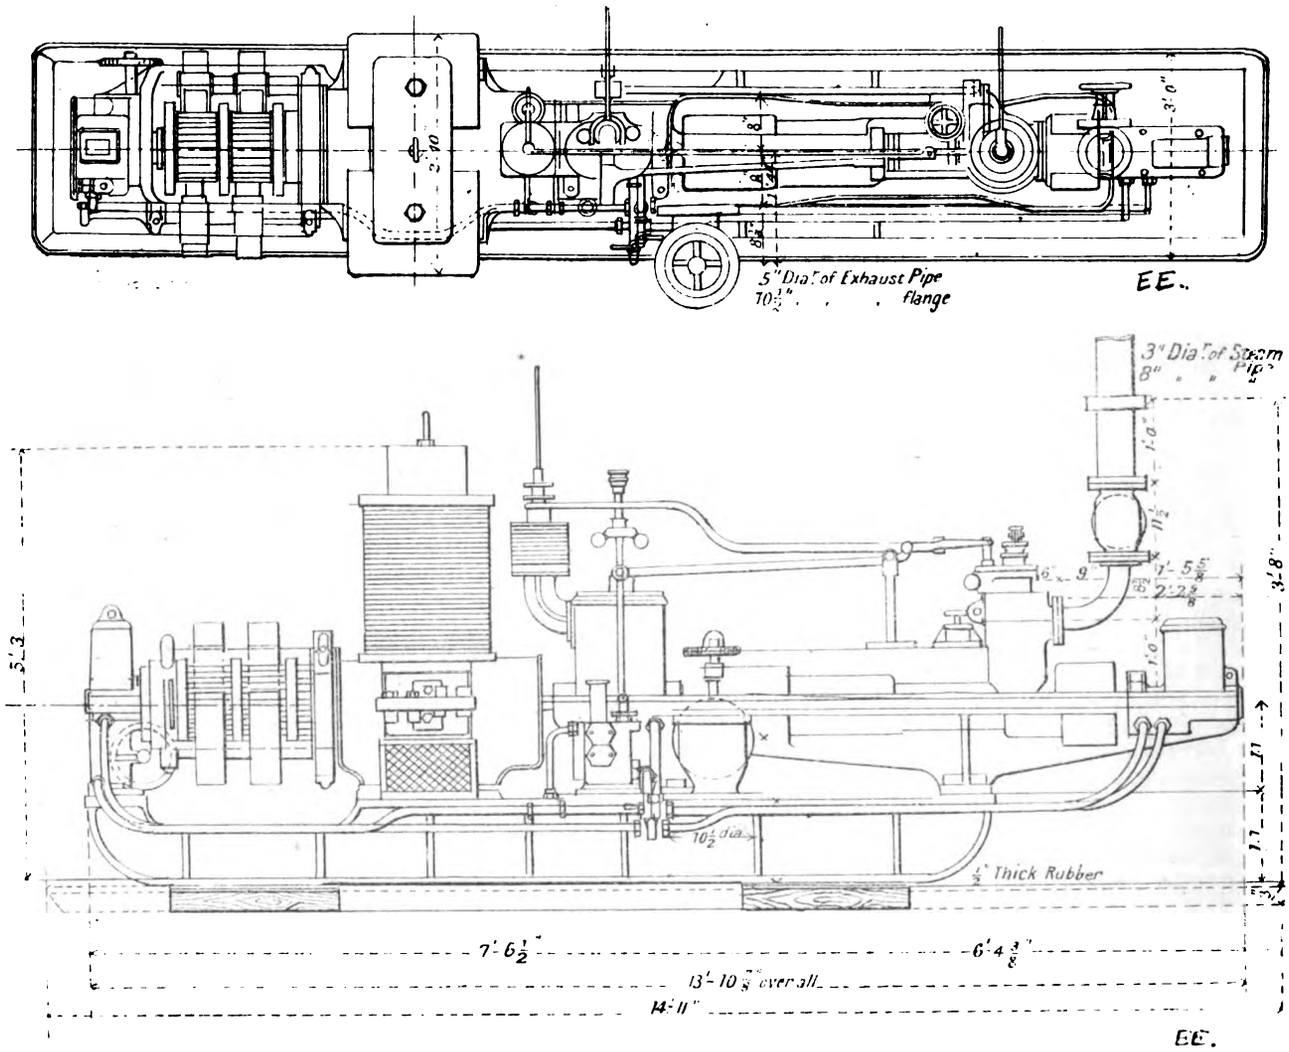
Digitized by Google

the generating plant, has been put down to the specification of Mr. Robert Hammond as consulting engineer for the generating plant, switchboards, etc.

Starting with the boilers, there are to be five of these, made by Messrs. Davey, Paxman, and Co., of Colchester. They are of the "Economic" type, and are capable of evaporating 5,000lb. of water per hour at a working pressure of 140lb. per square inch, using feed water at a temperature of 60deg. F. Four of these are 14ft. long by 7ft. 6in. in diameter, but the fifth is larger, being 14ft. 6in. by 8ft. in diameter. At present, however, only three, including the larger one, are in position. Hopkinson's fittings and valves are used throughout. There are four Brown's patent Berryman feed heaters, and the boilers are fed through these by electrically-driven Hayward Tyler plunger pumps supplied by the Electric Construction Company. Injectors are provided so as to give an alternative feed in case of breakdown. The steam-pipes are supplied trically governed, so that when the dynamo is working alone regulate as though it were compound wound. The full details can be seen from the illustrations, which also show the connections for the duplicate steam-pipes. The foundations required for these turbines can be exceedingly light, as the absence of reciprocating parts prevents all tendency to vibration. Hence the set is especially valuable for crowded parts of large towns, where space is valuable, and where stray vibrations are heavily taxed as nuisances.

It will be seen that the maximum output is 300 kilowatts, but there are extensions contemplated. On a basis of 15,000 16-c.p. lamps it would look as though these would be necessary, though it must be remembered that the Charing Cross Company is always at hand as an additional source of supply.

With regard to the engine-room, it may be added that there is an overhead traveller by Messrs. Arnold Goodwin and Son, of Southwark. Ventilation will be provided for by



FIGS. 2 AND 3.—Plan and Elevation of Parson's 75-K.W. Steam Turbine and Dynamo.

by Messrs. John Spencer, of the Globe Tube Works, Wednesbury, and are entirely in duplicate, so that one set can be cut off for repairs.

It has been mentioned before that, so far as room is concerned, the designer of the plant had anything but a free hand, and when the space is seen into which the generating machinery has had to be put, it is obvious from the first that anything in the nature of engines with rope-driven dynamos was out of the question. There was simply no room for them. The only possible choice was between more or less compact forms of machine, with the proviso the more compact the better. As the result, steam-turbines have been adopted, and the generators consist of four turbo-dynamos, made by C. H. Parsons and Co., of Newcastle-on-Tyne. Each of these has a capacity of 75 kilowatts—*i.e.*, 710 amperes at 105 volts. They run at a speed of about 4,000 revolutions per minute. Three sets are shown in Figs. 1, 2, and 3. The machines are used in parallel and are shunt wound, but elec-

Blackman fans, and there are also a number of these in the offices, laundry, and corridors. The engine-room and boiler-house adjoin, but one regrettable result of the building having been completed before any of the machinery was designed is that the boiler-house floor is somewhat above the level of the engine-house. This, however, was inevitable. Another difficulty that occurred was to devise a convenient way of getting in the coal supply. Coaling is always a dirty and messy operation, and it is obvious that it should be done as much as possible out of sight and out of the way of the visitors of the hotel. The original plan by no means fulfilled these requirements, but Mr. Beckton has been able to work out one that will meet the difficulty. The principle is that the coaling will be done from below instead of from above, the coal coming in on carts by the lower roadway to a point underneath the main quadrangle and about 12ft. or 16ft. below the coal-store. They will be then lifted by a two-ton lift to the store, which is 6ft. above the boiler-level. The day's supply will

Digitized by Google

be shot from the store through a shoot into the bunker-room, which holds about 25 tons, and thence distributed by barrow as required. The ashes will be got rid of through a door into Ivybridge-lane, and thence by the lower roadway.

Reference has been made before to the fact that the Charing Cross Company is available for an alternative supply of current. A special main has been laid from that company's generating station into the building, and there are already a considerable quantity of lamps running whose current comes from this source. Provision has been made on the switchboard for using either the company's current or that generated on the premises. So far as the latter is concerned, the current is taken from the generators to massive copper 'bus bars at the back of the board, and thence distributed to the various panels. The board stands directly opposite the machines. It has a framework of wrought iron with slate panels. As may be supposed, the changing-over switch is a prominent object in the centre of the board. It is a massive affair, and it is confidently expected that it will effect the change over so instantaneously that the resultant flicker in the lights will not be perceived. There are ammeters for each dynamo and circuit and two voltmeters over the board. The hotel installation is on the two-wire system, while the Charing Cross Company's is a three-wire one—all three wires being brought into the building. The company's wires therefore do not go on to the 'bus bars, but direct to the two main circuits into which the wiring is divided, so that at any rate an approximate balance may be obtained.

The general principle of the wiring is to take two circuits into each block of buildings, and a separate circuit for the arcs. It is intended at present to use the company's supply entirely during periods of light load, but a contract has been concluded by which heavy currents will be obtainable after a sufficient notice; but as the machinery consists of four units, it is hardly likely that two of the dynamos would be out of order at the same time, and hence there seems little likelihood of a heavy supply being required from the company.

A test-room is being equipped in connection with the engine-room.

So far as distribution is concerned, each of the four blocks will be, as far as possible, on an independent system of circuits, with a distributing board in each part of the building. Throughout the building the smaller switches are of the tumbler type, and those on the switchboard have spring contacts. It should be said that, in addition to the incandescent lamps, there are six arc lamps in the quadrangle and porches, and six more on the river front. These are 12-ampere lamps of the Brockie-Pell type, and besides these there is the illuminated fountain in the quadrangle, which will be described later on. The consulting engineer for the wiring of the hotel is Mr. Morgan Williams.

It is stated that in one way or another the cable for wiring purposes runs up to a total length of over 125 miles. In the large banqueting hall the lamps are grouped on massive electroliers, and this principle is in the main followed throughout what is called the Empire floor as well as in the ladies' drawing-room. The electroliers are characteristic of the period and style adopted in the various rooms.

On the Indian floor, however, where an Oriental style of decoration has been adopted and carried out with considerable boldness and freedom, an opportunity was afforded for a new departure. Throughout this floor the lamps are arranged in single lights. A large number of pendants are spaced at equal intervals over the ceilings and along the corridors, so as to give an equally diffused light almost entirely free from shadows. Cut-glass shades are here used with excellent effect. The design of many of these lamps appears to be copied from that of the hanging lamps that are a prominent feature in Eastern mosques. These are decidedly graceful in appearance and eminently appropriate to the decorations. The brilliancy of the illumination will be strikingly un-Oriental.

The same principle of equal distribution, but by carefully shaded lamps, has been applied to the billiard-room, which is on the Indian floor. In other parts of the hotel a compromise between the system of grouped or distributed lamps is adopted according to the circumstances of the case.

The arc lamps have already been mentioned. With these there will be an abundance of light in the quadrangle and under the large glass *porte-cochère*. An additional feature will be an electrically-illuminated fountain in the centre of the court. Underneath the quadrangle there is a 20ft. roadway. The apparatus for reflecting the light into the fountain is carried on a gantrey running across this. Before leaving the subject of the electrical machinery, it may be mentioned that all the laundry machinery will be electrically driven. "Castle" motors are used for this purpose. The contractors for this part of the work are Messrs. Manlove, Alliott, and Co., of Nottingham.

The staff of the hotel is to consist of about 700 persons and the distances are so great that one of the first question that strikes a visitor is, how is communication to be maintained with the various departments and how long will it take to get anything that is wanted. A large number of lifts provide for the actual conveyance of person or material, while the forwarding of orders will be greatly facilitated by a very complete system of telephones. There is a telephone to every room, and there is to be a sub-exchange board on every floor, so that the visitor can speak to the service room or through to the manager's office. Again, each sub-exchange is connected by a trunk line to a principal exchange situated in the sub-basement of the southern block. It will therefore be possible, practically, to speak to any part of the buildings, the system being similar to a public exchange.

INSTITUTION OF ELECTRICAL ENGINEERS, April 30.

At last night's meeting of the Institution the following paper was read:

ON RAILWAY TELEGRAPHS, WITH SPECIAL REFERENCE TO RECENT IMPROVEMENTS.

BY W. LANGDON, MEMBER.

The subject with which this paper deals is one which has not, for some time, claimed the consideration of members of this Institution. The progress which has attended the application of electricity to railway telegraph work is in no way comparable with that which has in recent years marked its progress in relation to lighting and power. Such advances as have been achieved are to be found more in minor details than in any radical change. Probably the most noticeable fact presides in the greater freedom from serious breaksdown which we now enjoy, and in the growth of the telegraph service—a striking testimony of its increasing utility. Competition is a stern and exacting master. The train service of to-day must not only be well equipped, but it must work well to time. That which yesterday was thought ample, is to-day found wanting. Each day ushers in fresh demands, greater elaboration, greater exactitude! How useful a factor the telegraph becomes in enabling this to be accomplished is probably known only to those in whose hands rests the responsibility of that which has to be done.

In the year 1880 the late Mr. Edward Graves, one of our past-presidents, and for many years our honorary treasurer, brought under the notice of members some extremely interesting statistics in relation to the progress of telegraphy, in which he produced a comparison between the mileage of wire and the number of instruments in use on the various railways in Great Britain in 1869 and 1879.

By the courtesy of the controlling officers of practically the entire railway service of the country—to whom my acknowledgments are gratefully tendered—I am, with the exception of the data of some two or three of the minor companies, enabled to bring forward this information another decade and a half. Accepting Mr. Graves's figures as a basis, and making allowance for the expansion of those systems the returns for which are not to hand, we get the following approximate results:

		Miles.	Increase.
Mileage of wire employed for railway purposes.	1869	27,204	—
	1879	62,099	34,895
	1889	84,423	22 324
	1894	99 296	14,873
		Instruments.	**Increase.**
Number of instruments employed for railway purposes.	1869	10,121	—
	1879	46,847	36,726
	1889	100,590	53,743
	1894	130,339	29,749

Digitized by Google

It will be understood that these figures are not put forward as absolutely correct. They may, however, be accepted as fairly representative, and as a very near index of the progress and increasing influence of the telegraph service.

Prior to 1870 block signalling was but sparsely employed. During the decade 1869-79 it met with general adoption, which accounts for the large increase in both instruments and wire during that period. The increase during the half decade 1894 is, in relation to that of the preceding decade, remarkable, as indicating that the expansion is still in active operation. These figures tell their own tale of utility in the management and regulation of railway traffic, while from the mileage of wire maintained by the railways for the Postmaster-General, amounting approximately to some 67,000 miles, it may be reasonably inferred that the railways are in no small degree contributing to the convenience of that branch of the public who from day to day seek the service of the Post Office wires. Let us pause but a moment to consider how the present enormous traffic of our railways, or the mass of matter which daily passes over the various telegraph services of the country, could possibly be dealt with without these aids, or how the conditions of commercial life would be effected by their cessation, and we at once become sensible of their value.

Individually, possibly few railways afford a more forcible illustration of the rapid growth of a railway telegraph service than that to which the author is attached. In 1878 the total mileage of wire on the line amounted to 9,816 miles, and the number of instruments to 7,702. The mileage of wire to-day exceeds 22,000, and the number of instruments closely approximates to 19,000. This large expansion is naturally calling for increasing accommodation for wires, and, in the interest of economy, for a careful study of the cost in both construction and maintenance.

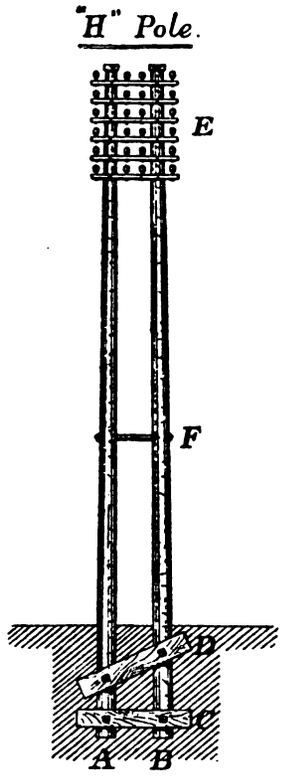


Fig: 1.

Poles.—One of the chief factors to which we are indebted for the greater stability of our lines of telegraph at the present time is the employment of poles which have been charged to a certain extent with creosote. In the session of 1873-74 a paper, "On the Preservation of Telegraph Poles," was read before this Institution, then the Society of Telegraph Engineers, in which the various processes for the preservation of timber were discussed. Of the several methods there referred to, the creosoting process may be regarded as the sole survivor. Creosoted poles are now almost universally employed. Their life, or the period they may remain in position without deterioration from decay, is still, to all intents and purposes, undetermined. Given a properly-seasoned pole, fairly dry when placed under the process, its life may reasonably be relied upon to cover the period the pole is required to stand before additions or alterations call for its replacement. It is neither necessary nor desirable that the timber of telegraph poles should be completely charged with creosote. The quantity of creosote impressed into telegraph poles is usually 8lb. to the cube foot of timber; and this quantity, where the wood is properly seasoned and well dried, will be found to have penetrated to the core or heart-wood of the pole. It will thus form a complete protective shell, impervious to moisture; and in this lies the main advantage of the application. Timber which is thoroughly impregnated or saturated with creosote becomes, as soon as the oil is dissipated, devoid of much of its elasticity, and is then more easily broken than if the heart-wood of the timber is allowed to remain uncreosoted. There are points where creosoted poles are objectionable—such, for instance, as station platforms. Here, whereas in former years Memel timber was usually employed, it is preferable to use pitch-pine. Pitch-pine is more durable than Memel. It is more resinous, and thus more antagonistic to the reception of moisture; and it is the moisture which, traversing the fibre of that portion of the timber in the soil, under the influence of the warmer atmosphere above the ground line, disintegrates it at or about the ground level, and so destroys it. The number of wires which have now to be accommodated, in many instances, call, not merely for stout poles, but for structures such as H poles. These structures (Fig. 1) consist of two poles, A B, braced together at the foot by a slab of wood, C, as nearly as possible at right angles to the poles, and a further slab, D, some 4ft. from the butt end of the poles, arranged diagonally; the arms, E, at the top of the poles act as the tie-pieces at that end of the structure. These are sometimes, especially in high poles, supplemented by a stiff iron rod, F, passing through the two poles, at right angles to them, or by rods crossing one another diagonally, tied together in the centre. The practice has been to allow the two poles forming the basis of this structure to have a slight spread at their butt ends—*i.e.*, taking a centre line down the poles, the distance between these lines at the top of the poles being some 12in. less than that between the centre lines at their butt ends. When poles become crowded with wires, this, with respect to the lower arms, detracts from the regularity of the insulators and wires. It is better that the poles should be equidistant throughout. You have then merely to provide for the increasing thickness of the timber in order to ensure perfect regularity in the position of the wires from top to bottom. The Midland Railway having recently been called upon to construct for the Postmaster-General a section of an important trunk line to Scotland, it has been necessary to convert an existing line of single poles into an H line. To construct these H poles, braced together at the foot, as shown in Fig. 1, would have meant the replacement of the entire line—a most expensive operation. Under these circumstances, the existing line of poles has been allowed to stand. At the proper distance a pole, B (Fig. 2), to match the standing pole, A, has been placed in position, care being taken to cut off the butt end so as to ensure a flat basis. It has then been allowed to stand some days, so as to become well settled in its position, after which slots for the arms are cut to correspond with those on the original pole. The short arms are then one by one removed from the latter and replaced by arms 56in. long, which are bolted to the two poles. Where the old line of poles has been systematically constructed with the arms, say, 12in. apart, centre to centre, the appearance of

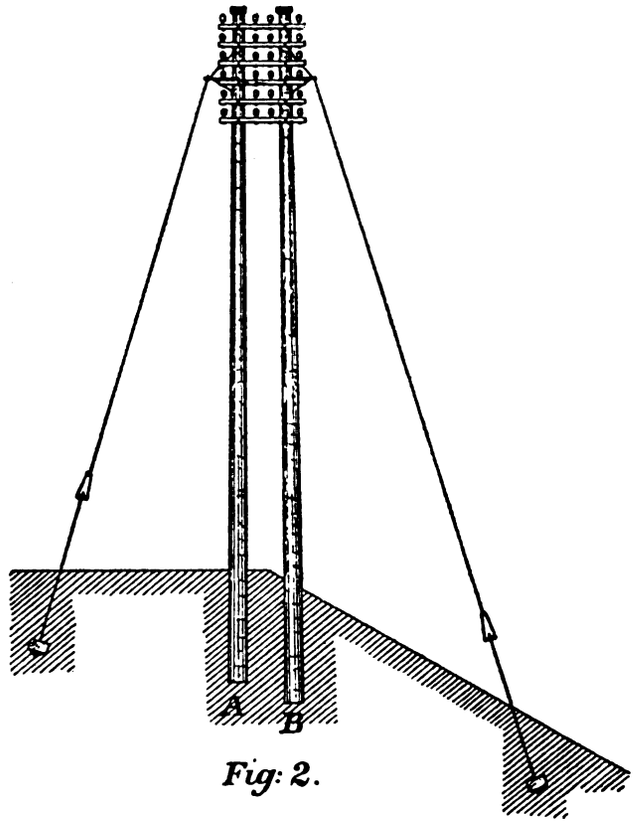

Fig: 2.

Digitized by Google

such a combination is in every way agreeable to the eye. It will be evident that without the diagonal tie-piece the poles might, under stress of wind, work themselves out of position. This has to be met by staying them in the same manner as a single line. Where, from exceptional causes, the poles cannot be stayed, the diagonal tie-piece should be employed. Photographs of sections of the line of poles thus treated are on the table. H poles are destined to be of great service. There is no reason why the number of wires should be limited to four on an arm. The 56in. arm may be replaced by a 72in. arm, accommodating six wires, thereby increasing the capacity of the poles one-third. We may even venture beyond this where the need for it exists, employing either iron arms, or wooden arms of larger scantling, in order to meet the weight of the wires standing on the outer side of the poles. The structure is one which, if well stayed, will withstand gales far better than single poles with half the number of wires, arranged two on an arm. Moreover, it will be observed that H poles, with six wires on an arm, lend themselves to telephone requirements. With the wires arranged two outside each pole and two between the poles, three groups or squares may be formed by each pair of arms, each wire of each "square" or "group" being maintained 1ft. apart. A photograph of poles so armed is on the table. Telegraph poles seldom commend themselves to the observer as an æsthetical subject; but uniformity in construction, with the poles well in line, or regularly following the contour of the road, evenly graduated for height, and uniformly armed and wired, with perhaps an ornamental top in exceptional places, will do much towards removing those objections which are not unfrequently raised against their presence.

Arms.—In the trimming of poles the most novel feature is the introduction of iron arms. Forty-four-inch tubular iron arms, specimens of which are before the meeting, have been employed for some 100 miles of the trunk telephone line recently erected by the Midland for the Postmaster-General. Some years prior to this shorter arms—tubular and rectangular, for carrying two wires—were experimentally employed by the author. No inconvenience whatever has so far attended their employment. The longer (44in.) arm (Fig. 3) is composed of 1¾in. galvanised iron tubing, A, ⅛in. thick, strengthened by a piece of larger gauge tubing, B, of same thickness, 2in. in diameter, carried over the centre portion of the 1¾in. tubing. The two tubes thus combined are practically homogeneous and very strong. The employment of these arms admits of a slight reduction in the length of the insulator bolt, which may, with advantage, have the shoulder of the bolt, as

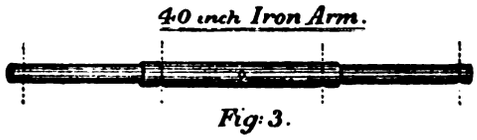

Fig. 3.

also the washer, hollowed out to fit the arm. Thus arranged, there is no possibility of the insulator twisting round. These arms should be very durable, and it is worthy of remark that they do not require so much of the pole cut away as is necessary for the wooden arm. The earth wiring of wooden arms has, the author believes, in some quarters been abandoned. That course has not been pursued on the Midland. Earth wiring, as illustrated by the sample placed upon the table, is still followed. With iron arms the need for earth wiring disappears. It is merely necessary to lay the main earth wire securely under the washer of the arm bolt. Clearly, where iron arms are employed, failure in insulation such as that produced by a broken or cracked insulator will readily make itself known. To what extent this will operate with respect to the iron arms experience must show. In a trunk telephone line discrepancies in the insulation of the four wires forming a square would appear to be undesirable factors. Whether such failure may be more readily traced with iron than with wooden arms has yet to be proved. The iron arms ought, where "earth" is the cause of failure, to give a more defined fault, and thus lead to its more ready removal. Iron arms and brackets, as well as iron poles, have in various forms been in use for years, especially for foreign lines; and probably no member of the Institution has a more intimate knowledge of their value than our past-president, Mr. Alexander Siemens. In slotting round poles for these iron arms it was at first thought that a V-shaped cut would readily lend itself to the reception of the arm; but experience has shown that it is better to slightly slot the pole, as though for a rectangular arm, and gouge out the base of the slot. The pole being round, the V-shaped cut fails to retain the arm in that rectangular position, in relation to the pole, which is necessary to give the line that trim and uniform appearance so acceptable to a good workman. In the employment of wooden arms there is nothing of a novel character to record. They are to-day very much as they have been during the last 20 years. It may not, however, be inopportune to raise the question whether English oak is the only timber from which they should be made. Doubtless English oak is more durable and stronger than other timber; but it is a question whether foreign oak—say Stettin—if cut under the conditions applicable to English oak—viz., well seasoned, free from knots, and free from sap—is not sufficiently durable and strong for the purpose. Arms cut from this description of timber have been in use on the Midland system for many years, and nothing has transpired to create a want of confidence in its suitability for such work. Another point worth considering is that of painting the arms. Paint, if applied when the timber is properly seasoned and dry, is, no doubt, beneficial; but paint applied to wood which does not possess these qualifications produces dry rot, and is, consequently, absolutely injurious to the timber, and dangerous to workmen when on the poles. Where the arms can be stacked by the user until thoroughly seasoned, they may with advantage be painted.

(To be continued.)

The following were the candidates balloted for:

Associates.—Fred A. Donnison, 29, Aberdeen Park, Highbury; Leo Arthur Hards, 57, Grosvenor-road, S.W.; James Leggat Kilpatrick, 23, Delafield-road, Charlton, Kent; F. A. B. Lord, 24, Billiter-street, London, E.C.; Ernest Wilmot Rees, Bron Siriol, Carnarvon; Louis Schramm, care of Electrical and General Engineering Company, 86, Leadenhall-street, E.C.; William Wyld, Corporation Electricity Works, Blackpool.

Student.—Edward A. Short, Saham-Toney, Walton, Norfolk.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

May 1, 8 p.m.—At the Institution, Great George-street, Westminster. Students' meeting. "Swing Bridge over the River Nene at Sutton Bridge," by Edward S. McDonald.

May 5, 8 p.m.—Ordinary meeting. "American and British Methods of Manufacturing Steel-Plate," by J. Head, and "Four American Rolling Mills," by S. T. Willmer.

May 7, 8 p m.—Forrest lecture. "Physical Experiment in Relation to Engineering," by Dr. A. B. W. Kennedy, F.R.S.

Institution of Electrical Engineers.

May 9.—Students' visit to the London Electric Supply Corporation's station at Stowage Wharf, Deptford. Train leaves Charing Cross at 10.20.

Society of Arts.

May 4, 8 p.m.—At John-street, Adelphi. Cantor lecture. "Applied Electro-Chemistry." By James Swinburne. (The second of four lectures.)

May 5, 8 p.m.—"Australia's Prospects in British Markets." By James F. Dowling.

May 6, 8 p.m.—"High Explosives and Smokeless Powders." By Hudson Maxim.

Iron and Steel Institute.

May 7 and 8, 10.30 a.m.—At the Institute of Civil Engineers, Great George-street. Meeting. (A list of papers to be taken is given in our "Notes").

Institution of Junior Engineers.

May 8, 8 p.m.—At the Westminster Palace Hotel. "Notes on Belgian Electrical Engineering Practice," by A. Austruther-Thomson and G. C. Allingham.

Chemical Society.

May 7, 8 p.m.—At Burlington House, Piccadilly. Ordinary meeting.

Royal Institution of Great Britain.

May 1, 5 p.m.—Annual Meeting; 9 p.m., "Chronographs and their Applications to Gun Ballistics," by Colonel H. Watkin.

May 4, 5 p.m.—Monthly meeting.

May 5, 3 p.m.—"Ripples in Air and on Water." By Prof. C. V. Boys.

May 7.—"Metal Working in Japan." By W. Gowland.

May 8, 9 p.m.—"Electric Shadows and Luminescence." By Prof. S. P. Thompson.

Institution of Mechanical Engineers.

May 1, 7.30.—At the Institution of Civil Engineers. Paper on "Steel Steam-Pipes and Fittings, and Benardos Arc Welding in connection therewith." By S. MacCarthy. "Research Committee on the Value of Steam-Jackets: Experiments on Locomotive Engine." By Prof. T. H. Beare and Bryan Donkin.

Society of Engineers.

May 4. 7 30 p.m.—At the Royal United Service Institution, Whitehall. "Hydraulic Rotative Engines," by A. Rigg.

Lambeth.—The electric lighting question, which for weeks past has been under consideration by the Lambeth Vestry, was settled last evening, when, by a majority of 44 to 15, the Vestry decided to hand over the electric lighting order to Mr. C. W. Sax.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

GASEOUS CRITICS.

In our last issue we commented upon some of the criticisms that the gas engineers had been making about electrical work, and pointed out the unfairness of some of their remarks. We have never hesitated in stating that for lighting, and even for heating purposes, gas and electricity are keen competitors. That electricity will win the day we have no shadow of a doubt, but, as has often been pointed out in these columns, the recent improvements made in the use of gas renders the competition keener and the result longer deferred. Some of the adverse comments have been directed against the return obtained by municipalities which have embarked in electric lighting work. There is nothing more misleading in this world than figures — except facts. Both facts and figures may be absolutely correct, yet utterly misleading. What are the facts about lighting? If we state them wrongly, we are open to correction; but our aim is to arrive at the truth, and not to give half-truths in order to mislead. In Great Britain, most of the towns are, and have been for years, lighted by means of gas. So far as the authorities are concerned, they have to pay for the public supply, and have nothing to do with the private supply. Nothing is more certain than the public supply being less remunerative than the private supply, but as a rule the one sooner or later involves the other. A municipal authority taking up the work of electrical supply can control that portion which is less remunerative and cannot control the other. It has then to commence with a supply which is known to be often produced almost, if not quite, at a loss, and to wait events for the supply of that which pays well. Take this fact into consideration in any discussion of municipal electrical supply, and the wonder is, not that huge dividends are unearned, but that working expenses are paid within a year or two of the start. Private houses already lighted by other means are not going to generally take supply from the mains. Here and there one will be connected, but the demand must necessarily be somewhat slow. Still, with all the difficulties to overcome, with the keenest competition to fight, it is remarkable how short a time passes before all expenses are paid. Compared with central stations equipped to supply a whole town, with no other illuminant competing, the present central stations are small and uneconomical, yet these can be made successful. Let us examine a case where an intelligent engineer has guided his corporation—not a large installation, but one of moderate dimensions—namely, that of Hanley. Mr. Lobley is one of the most competent of municipal engineers, and under his supervision Hanley has expended to the end of 1895 in electrical work £32,362. Of this £10,717 was expended during that year, so could not be very productive. The result of the first year's complete working was to sell 180,469 units, produced at a cost of 2·8d. per unit and sold at 4·58d. per unit, bringing in a revenue of £3,444 and a profit before allowing depreciation of £1,443. How the supply of public lighting gradually leads to the supply of private lighting may well be seen

Digitized by Google

from the accounts of the City of London Company. At the end of 1892 the number of customers was 242, increasing in succeeding years to 1,080, 2,740, 4,230 respectively; the net revenue corresponding to these years going from £500, estimated for 1892, to £16,940, £34,865, and in 1895 to £59,100. Just attempt to imagine what the result in either of these cases will be when the lighting of private houses in each district becomes general. Of course the price per unit sold will be lowered. In the case of the corporation, that follows a big return as a matter of course. Though, as we contend, it is unfair to give facts and figures relating to many installations without explanations, when the latter are forthcoming, instead of damaging electrical work, they tend to encourage it. We cannot pretend to be uninterested in this matter, but our interest will not prevent an earnest attempt to deal with the question so as to bring out the truth. Electrical work must progress because of its intrinsic merit, not by means of false witnesses, and, on the other hand, it will not be damaged by the suppression of important information.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

A PLEA FOR COMPOUND ARITHMETIC.

SIR,—The number 380,160 is, of course, that of inches in six miles. I know not how I came to copy it as one mile, but was meaning to contrast it with seven miles. In fact, however, seven furlongs make a better unit than a mile. The latter, 63,360in., has but 94 divisors, while seven furlongs, or 55,440in., is cumetric, and has 118. The number of divisors is found by deducting two from the product of the indices of all the factors, each augmented by one. Thus,

$$63{,}360 = 2^5 \cdot 3^3 \cdot 5 \cdot 11\text{;} \quad \text{whence } 8 \cdot 3 \cdot 22 = 96.$$

But

$$55{,}440 = 2^4 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11\text{;} \quad \text{whence } 5 \cdot 3 \cdot 2 \cdot 2 \cdot 2 = 120.$$

Yours, etc., E. L. GARBETT.

25, Claremont-square, N., April 24, 1896.

OBITUARY.

The death is announced of Mr. H. J. Vose, M.I.C.E., of Cardiff, superintending engineer of the Post Office telegraphs for the South Wales district. Mr. Vose passed practically the whole of his official career in the engineering department of the telegraphs. He joined the staff of the late Mr. Edward Graves in 1871. Mr. Graves was then divisional engineer of the old north-western district, with headquarters at Birmingham. On Mr. Grave's promotion to the position of engineer-in-chief in 1878, Mr. Vose followed him to London, and acted as his confidential assistant, with a short break, until his death in November, 1892. Mr. Vose was then appointed, on the recommendation of the present engineer-in-chief, Mr. W. H. Preece, to the superintending engineership at Cardiff, in succession to Mr. J. Gavey, who removed to London on promotion as principal technical officer on the head office staff. Mr. Vose possessed in a marked degree the attributes that make a man a charming personal companion, but he was none the less an excellent man of business. He carried out the many delicate and important duties entrusted to him with admirable skill and tact, and he had the interests of the department he served very much at heart. He had been in failing health for a considerable time past, and for at least 12 months his condition was such as to cause much anxiety to his friends and colleagues. But throughout the long course of the insiduous disease from which he suffered he never once lost heart. It was hoped that his comparative youth would eventually enable him to throw off the disorder, and recent reports of his condition favoured this view, but on Sunday last he suffered a severe relapse and passed peacefully away on Tuesday morning. Mr. Vose was in his forty-sixth year, and he leaves a widow and three children to mourn his loss. He will be greatly missed by his brother officers and by innumerable personal friends, both within and without electrical circles. He was an enthusiastic Freemason.

REVIEWS.

Physical Units. By MAGNUS MACLEAN, M.A., D.Sc., F.R.S.E. Biggs and Co., 1896.

This is a reprint of articles originally published in the *Electrical Engineer* in the year 1894. It deals with the mechanical and other physical units for the most part in a careful and methodical manner, and it is up to date in giving the suggestions with regard to the names of magnetic units made at the meeting of the British Association at Ipswich last year. The author also discusses at length the relations of the various physical quantities to the fundamental magnitudes—length, mass, and time. But here the book shows some signs of having been hastily put together, and in some places would be a source of confusion rather than of help. It is, however, everywhere full of suggestion and interest. There is a useful collection of 32 tables at the end of the book, and a good index.

It in no way supersedes the "classic" book of Prof. Everett on the subject, but is in some ways complementary to that book, as certain points are discussed in it in greater detail. The inaccuracies in connection with dimensions are the most serious drawback to the book, and should be corrected in a second edition. Thus, on p. 17, the gravitation coefficient, k, in the formula $F = k\frac{mm^1}{d^2}$ is given as so many *dynes* on the C.G.S. system, whereas its dimensions are evidently $L^3 M^{-1} T^{-2}$, its value being

$$\frac{1}{15{\cdot}43 \times 10^6} \frac{(\text{cm.})^3}{\text{gm.}\ (\text{sec.})^2} = \frac{1}{963 \times 10^6} \frac{(\text{ft.})^3}{\text{lb.}\ (\text{sec.})^2}.$$

The confusion seems to arise from not considering that when a quantity is *completely* stated, its value is independent of any particular system of units. It is in this that the advantage of knowing the *dimensions* of the various quantities is most apparent, and, indeed, it is in this way only that dimensions come in naturally and take care of themselves. On p. 26 g is used, not for the acceleration due to gravity, but for the number denoting that acceleration in the appropriate system of units. Of course, this is often convenient, but in a book treating dimensions carefully it would have been well to draw attention to this special use of the symbol. It is really taking g as the *ratio* of the acceleration due to gravity to the unit acceleration in the system of units considered. The equation at the foot of p. 42 is wrong. It should read:

1 foot-pound =

$$32{\cdot}2 \frac{(\text{ft.})^2 \times \text{lb.}}{(\text{sec.})^2} = 32{\cdot}2 \frac{(30{\cdot}48)^2 \times 453{\cdot}6}{1^2} \frac{(\text{cm.})^2 \times \text{gm.}}{(\text{sec.})^2}$$
$$= 13{\cdot}56 \times 10^6 \text{ ergs.}$$

The alternative mode of deducing the same result given at the top of p. 43 is correct and neat and instructive. Lower down on this page it would have been better to write

$$t^2 = \tfrac{1}{32}\,(\text{sec.})^2 \text{ instead of } t^2 = \tfrac{1}{32}\text{;}$$

and

$$m = \frac{6 \times 32}{24}\text{lb. instead of } m = \frac{6 \times 32}{24}.$$

The test suggested in § 37 is a most useful and instructive one, but the equation L = M/D, or l = Y/D (to avoid confusion of M with mass), given at the foot of p. 47, does not satisfy this test. For the dimensions of Y are

Digitized by Google

$L^{-1} M T^{-2}$ (p. 37), and those of D are $M L^{-3}$; therefore the dimensions of Y/D are $L^2 T^{-2}$. The equation should be $l = Y/g D$—*i.e.*, $l = Y/w$, where w denotes the weight per unit volume (or specific weight) of the material; and the velocity of the wave motion is given by the equation $v^2 = Y/D$. The electric and magnetic quantities are carefully defined, and their dimensions given in terms of L M T and the mysterious K and μ, whose possible natures have been so ably discussed by Mr. W. Williams in a paper referred to by the author (p. 9).

The relations in § 54 are very confused in dimensions. Surely the first line should be $B = \mu_0 H + 4\pi I$. All these equations should satisfy the test of § 37.

The practical electrical and magnetic units are carefully discussed, and references are given to important papers bearing on them. It might have been well to *tabulate* the modes of measuring the various quantities in terms of those to which names have been given, together with some of the equations connecting the named quantities, so that a student could have a birdseye view of the whole scheme of units as at present developed. The Order in Council on Electrical Units and Standards of August 23, 1894, is given in an appendix.

The discussion on thermal quantities does not seem to be quite so satisfactory, statements of dimensions being confused and mixed up with questions of units. It cannot be too strongly urged that the dimensions of a quantity have nothing to do with systems of units. Of course, we cannot *measure* without systems of units—*i.e.*, without standards of reference—but the nature of a quantity has nothing to do with whether we are able to measure it or not, and its dimensions have to do with its nature, not with its measurement. Dimensions come before units, and are superior to and independent of them.

An instance of confused dimensions occurs on p. 94, where the thermal capacity of a body is first defined as the quantity of heat necessary to raise its temperature one degree (it should rather have been "the quantity of heat given to it *per* degree rise of temperature," *dimensions*, $L^2 M T^{-2} \theta^{-1}$); and then it is said that thermal capacity per unit volume is a mere number—viz., the *ratio* of the quantity of heat necessary to raise the substance through unit difference of temperature to the quantity necessary to raise an equal volume of water through unit difference of temperature. Surely here is an example of confusing a quantity with the numerical part of its expression in terms of some standard. The dimensions of thermal capacity per unit volume are $L^{-1} M T^{-2} \theta^{-1}$, which may be reduced to $L^{-3} M$ if we take the dimensions of θ as $L^2 T^{-2}$. It is a question, however, whether in the dimensions of thermal quantities (as also in those of electrical and magnetic quantities) it is advantageous to endeavour to express everything in terms of L, M, and T only. It seems better to keep temperature (θ) as a fourth fundamental quantity until we definitely make up our minds to define it as energy of molecular vibration per unit mass ($L^2 T^{-2}$) and measure it accordingly. If we do so define it, then thermal capacity per unit mass *is* a pure number—namely, the ratio of the increase of total thermal energy given to the body to that part of it which exhibits itself in a rise of temperature. But thermal capacity per unit volume can never be a pure number.

The thermal capacity of water per unit mass is what is commonly called the mechanical equivalent of heat, and is denoted by J. It might be called the absolute specific heat of water. Its value is given on pp. 93, 94, and its dimensions are correctly given on p. 93, but are incorrectly stated on p. 101. We have

$$J = 42 \times 10^6 \frac{\text{ergs}}{\text{gm.-degree centigrade}} = 780 \frac{\text{foot-pounds}}{\text{pound-degree Fahr.}}$$

The thermal capacity of a mass, M, of any substance is $M c J$, where c is the (relative) specific heat of the substance as defined in § 102, its absolute specific heat being $c J$.

Entropy is somewhat carelessly defined on p. 98, but probably only for the sake of obtaining its dimensions, which are the same as those of thermal capacity. No mention is made of the calorie (or the therm) as a unit of heat, perhaps because its value is not at present well defined, "as no definite temperature has been chosen" (p. 93) for defining it. There are, moreover, two calories (Guillaume, Unités et Etalons), the greater calorie being the heat necessary to raise a kilogramme of water 1deg. C. (about 42×10^9 ergs), and the lesser being the amount required to raise a gramme of water 1deg. (42×10^6 ergs).

The question of a satisfactory unit of heat was brought up at Ipswich, and is now under consideration by the Standards Committee of Section A. The author consequently has considered more the nature and dimensions of the various thermal quantities than the mode of measuring them and the magnitudes of their units, which all depend on the magnitude of the unit of heat.

Taken altogether, Dr. Maclean's book is a useful addition to the literature on units, being full of valuable references and extracts, and containing a great number of useful tables.

Coopers Hill, April 16, 1896. ALFRED LODGE.

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

BY DR. ARMSTRONG, F.R.S.

(Continued from page 466.)

The dissociation of water takes place more particularly in contact with heated platinum—copper, although readily oxidised, appears to have no specific influence in promoting its decomposition. Platinum, however, occludes both hydrogen and oxygen, and may be supposed to be always charged with one or other of these gases—so that if the decomposition of water at high temperatures by platinum takes place within a circuit including one or other of these gases, the E.M.F. required to produce the change will be lower than that developed in the formation of water owing to the operation of a back E.M.F. It may be that heated copper does not decompose water, both because it does not polarise as does platinum, and perhaps, also, because the heat of formation of its oxide is lower than that of water under all conditions.

H. B. Baker's observations on the influence of moisture on the decomposition of ammonium chloride by heat (*Trans.*, 1894, 65, 615) are of great importance as the first of their kind, and must serve to direct attention to the value of further experiments of a similar character. It does not appear to me that we are yet justified in assuming that if dry such a substance would not decompose if heated; should we not perhaps rather consider that it would decompose somewhat suddenly when a sufficiently high temperature was reached—when the temperature was, in fact, a trifle higher than that corresponding to its heat of formation? The presence of moisture would promote decomposition because it is capable of interacting exothermically with one of the products—viz., hydrogen chloride. As change is influenced in both directions by moisture, the rate at which it would proceed in a case like that of ammonium chloride would, therefore, depend on the amount of moisture present; if the amount were very small, the pressure of dissociation would be attained only after the lapse of a considerable interval of time. The interesting account recently given by Rose (*Trans.*, 1895, 61, 893) of his observations on the influence of moisture on the pressure of dissociation of gold chloride—the first of their kind made to test this view—I think, clearly appears to afford confirmation of the correctness of this conclusion. With reference to this question, it may be here suggested that the occurrence of but slight decomposition when calcium carbonate is strongly heated in almost closed vessels may be due, not only to the fact that under such conditions the maximum opportunity is given for recombination, but also to the almost complete exclusion of moisture under such conditions. The practice of burning chalk wet is calculated to favour the maintenance of the "back E.M.F." developed in the interaction of lime and water to the utmost possible extent, and thus to hasten the rate of change; in other words, the acceleration is not the outcome of the removal of the gaseous products of change alone. Similar considerations apply to the incomplete *per saltum* combustion of gaseous mixtures at high temperatures.

It an interesting question whether compounds such as potassium chlorate, which decompose exothermically, will be affected by the presence of moisture or substances exercising equivalent effects; and this enquiry is clearly of special importance in connection with that into the stability of explosives. Baker's experiments have afforded negative results, but the subject is deserving of much closer experimental study. In such cases we are dealing with closed systems in a measure comparable with a charged Leyden jar, in which there are parts capable of interacting kept asunder by a non-conductor. The question is whether change be induced by communication being

* Presidential address delivered before the Chemical Society.

Digitized by Google

set up between these distant parts by the interposition of an external conductor, or, in other words, the completion of a circuit; or whether it be the outcome of a disturbance similar to that which would have the effect in the case of a Leyden jar of smashing aside the dielectric at some point, and consequently of bringing into contact the two coatings previously kept apart. The manner in which the decomposition of potassium chlorate is promoted by the presence of various substances might be regarded as evidence in favour of the former view were it not that anything which would give rise to changes developing a back E.M.F. would at once alter and, of course, increase the rate of change, and such actions are clearly not impossible in the case in question. It would be a matter of great interest to closely study the behaviour of some of the complex carboxylic acids which lose carbon dioxide when heated, or of the keto-acids from which carbon monoxide is evolved, with the object of ascertaining whether the rate of change is in any way dependent on the amount of impurity present—whether, in fact, such compounds would prove to be the more stable the greater the care taken in their purification, including dehydration under purification; but it is not to be expected that positive results will be attained in such cases until the approach to purity becomes very close. In the case of single substances undergoing rearrangement of parts it is not unlikely that "residual affinity" may come into play as much as it does in the case of ordinary interactions, and, therefore, that such decompositions will equally depend on the realisation of particular conditions; in other words, that the stability of compounds ordinarily reckoned very unstable may be very considerable in the pure state.

The instability of liquid ozone, to which attention has been drawn by Dewar and Liveing's observations, for example, may not be an intrinsic property of ozone in the liquid state, but may be conditioned by the circumstance that being liquid it is more readily brought into circuit or coupled up with impurities which happen to be present, so that opportunity is given for change to set in. The decomposition of liquid ozone would seem, in fact, to be comparable with that of a liquid system of sulphur dioxide, oxygen, and water, in which change occurs somewhat readily, although a gaseous mixture of the same substance is stable, according to H. B. Dixon.

The argument that changes generally all occur within compound circuits may, perhaps, even be extended to complex molecules undergoing change locally, and, indeed, such a step is but an application of the principle already made use of in explanation of fermentation. Thus it is now well known from E. Fischer's observations that when certain salts of gluconic and similar acids are heated they are converted in isomeric acids in consequence of a change in orientation being brought about which is purely local, affecting, as it does, only the single asymmetric carbon atom to which the carboxyl group of the acid is attached. The change is therefore clearly one which takes place within a local circuit, and apparently requires for its occurrence the establishment of certain special conditions. Lastly, it may be pointed out that cases of so-called tautomeric, or, as I prefer to call them, isodynamic, change would be easily explicable in terms of the theory here advanced, without in any way regarding them as spontaneous manifestations of inherent intramolecular activities.

I would here direct attention to the interesting discussion which has taken place within recent years as to the origin of flame spectra, as to whether such spectra are heat effects pure and simple, or conditioned by the occurrence of some form of chemical change (compare Smithells, *Phil. Mag.*, 1894 [5], 37, 245, where reference is made to the work of several observers bearing on this subject), questions on which the last word is clearly far from being said. This, moreover, is but one aspect of the wider and deeply interesting problem as to the nature of the changes occurring in flames generally, and of those which give rise to luminosity. It has long been taught that the hydrogen is the more combustible element of hydrocarbons, and, doubtless, this doctrine has been too dogmatically and exclusively taught; but the more modern opposite view, which is tending to become fashionable, is probably based on an equally narrow interpretation of the phenomena, which, it can scarcely be doubted, are of a very complex character and likely to defy our powers of analysis for some time to come. Personally, I see no absurdity in the idea that the hydrogen is first burnt and carbon liberated, and the water subsequently unburnt by the carbon; but I prefer to represent such combustions as occurring within systems comprising at least oxygen, hydrocarbon, and water, and the products as being water, carbon monoxide, and hydrogen. In such a case, I think it would be incorrect to speak of either constituent as the more combustible; the nature of the change must depend on the nature of the circuit within which the change occurs, and this may well vary with the conditions.

I have always felt attracted to the views of the origin of luminosity in flames put forward by Frankland so far back as 1867, in a remarkable course of lectures delivered at the Royal Institution, which were fully reported at the time in the *Journal of Gas Lighting*, and it has seemed to me that the theory has received far less attention than should have been accorded to it. Interest should be revived in the subject by the recent observations of V. B. Lewes (*Proc.*, Roy. Soc., 1895, 57, 450) on the decomposition of acetylene at high temperatures, which have led him to suggest that this compound plays the chief part in promoting luminosity in hydrocarbon flames, and that the heat liberated during its decomposition endows the carbon particles produced from it with an incandescence far higher than corresponds to the temperature of the flame. It appears to me that while accepting this as a partial explanation, it is unnecessary to suppose that luminosity is consequent on the production of presumably solid carbon particles; the conversion of acetylene, or other hydrocarbons, at high temperatures into hydrogen and carbon, although a decomposition in the ordinary sense of the term, is doubtless a change involving the interaction of several molecules, and the consequent formation of carbon molecules of a high order of complexity together with hydrogen molecules; and it is exothermic because the energy liberated in the combination of the carbon atoms among themselves, and also of the hydrogen atoms, is far in excess of that absorbed in the decomposition of the hydrocarbon molecules. The initial luminance may therefore well be that of the molecules at the moment of formation prior to condensation, although the continued incandescence of the carbon molecules after their reduction to the solid state probably contributes largely to maintain luminosity, giving to hydrocarbon flames their special value perhaps. But this is to explain the phenomena in terms of Frankland's theory, as I understand it, and as appears to be necessary in order to explain the luminous appearance of a hydrogen-oxygen flame burning under pressure, and other cases in which the products of combustion are gaseous.

Of the many directions in which the introduction of electrical conceptions into chemistry promises to be of service, the determination of the "electromotive efficiency" of chemical change appears to be one of the most important.

Braun in Germany, and in this country our late distinguished fellow, Alder Wright, whose loss we so much deplore, have devoted much attention to the determination of "chemical affinity" in terms of E.M.F., following the method first adopted by Wm. Thomson (now Lord Kelvin) and successfully applied by him to the Daniell cell. Thomson's calculations involved the assumption that the energy of chemical change becomes wholly converted into electrical energy, but the comparisons which have been since made *seem* to show that in cells other than the Daniell this is rarely, if ever, the case. Helmholtz and others, in fact, have proposed to draw a distinction between free and bound energy, the latter being that portion of the total energy of the system which is not convertible into electrical energy but becomes frittered down into heat in chemical changes. It has always seemed to me that most physicists who have discussed these matters have had far too little feeling as regards the nature of chemical changes, and that the conclusions have been too often based on *a priori* considerations. Obviously, it is necessary to know the precise character of the changes going on under particular conditions in any cell before the attempt can be made to ascertain whether the E.M.F. developed is the precise equivalent of their "chemical energy." Our knowledge as to what goes on in solutions is so vague, however, that at present we can never assert that we know precisely what is happening in a particular system." As Herroun has pointed out in an important paper on "The Divergence of E.M.F.'s from Thermo-chemical Data" (*Phil. Mag.*, March, 1889, 209), there is reason to believe that in the case of a number of metals, silver and mercury, for example, it is probably altogether wrong to base calculations on the assumption that the heat of formation of a hydrated salt, or of the salt in a solution of the concentration of that which is ultimately formed in the cell in which the metal is dissolved, is the heat of formation to be made use of in the calculation of E.M.F.; we must, in many cases, rather assume that the anhydrous salt is alone formed in the circuit. In like manner Robertson and I have contended (Royal Society's *Proceedings*, 1891, 50, 108) that in the lead sulphuric acid-lead peroxide cell the active acid is not that actually filled in, but a lower hydrate or the anhydrous acid; in this manner it is possible to account for the cooling observed during the discharge of an "accumulator," as the separation of molecules of the acid from a solution (by dissociation) would, of course, involve cooling.

If, as Faraday has said, the forces termed chemical affinity and electricity are one and the same, there does not seem to be any reason why there should not be an integral conversion of the energy of chemical change, nor any necessarily valid objection to the view that an explanation of the discrepancies which have been observed is to be sought for in phenomena that prevent an integral "conversion" from being realised. Meanwhile, the determination of E.M.F. may be of great service as enabling us to discriminate between a number of conceivable modes in which change may occur in a given case. Thus it is clear, for example, that whereas a metal like zinc is dissolved by, say, sulphuric acid in a circuit of which the hydrated, not the anhydrous, acid forms a part, metals like silver, mercury, lead, and even nickel (compare Herroun, *loc. cit.*, p. 226) require

Digitized by Google

to be coupled with, it may be, the anhydrous acid, but in any case with one which is less hydrated than that which is active in the case of zinc; the anhydrous salts formed in such cases apparently undergo hydration outside the circuit of electrolytic change, and their hydration only affects the temperature of the cell, so that the phenomena are comparable with those which attend local action in a cell in which ordinary or imperfectly amalgamated zinc is used.

In other words, it is not a mere question as to what is present n a solution; the *compatibility* of the various substances must also be considered, and of this we know very little at present. Incompatible molecules may get in the way and hinder change, but only compatible molecules can co-operate in changes, so that we cannot simply write $C = \frac{E}{R}$, and treat R as the resistance of the solution as a whole in which the change takes place; it may often be the resistance of circuits within the solution, the precise nature of which it is difficult, if not impossible, to determine.

It is not only on account of the very different behaviour of different metals towards acid solutions, however, that the discussion of the electromotive efficiency of various combinations is of interest; it is also possessed of a side interest as throwing light on the behaviour of the water itself, which is in so many respects peculiar. If it be possible for sulphuric acid molecules, for example, to separate from a solution to dissociate out—and act separately in the presence of water, without producing any direct effect on the E.M.F. of the cell within which the change occurs, the necessary energy being furnished by the liquid, which thereby becomes reduced in temperature, it is clear that the dissociation of *hydrates* is in a measure a phenomenon of a peculiar order. It might be supposed that the energy concerned in such changes is the so-called "bound" energy of Helmholtz, but this can hardly be the case, as that which is "bound" when the acid is included within a circuit with lead is apparently "free" when included in a similar circuit containing zinc in place of lead.

In discussing elsewhere the question whether a line cannot be drawn between cases in which interaction will, and those in which it will not, take place between two pure substances, I have pointed out that, although there is little to guide us, it seems not improbable that water has special properties which enable it to act directly, at least in cases in which dissociable composite electrolytes could be at once formed. If this be the criterion adopted, sulphuric anhydride may be expected to combine at once with water without the intervention of any other substance, but not with hydrogen chloride; and alcohol to mix with water without undergoing hydration, just as ammonia and hydrogen chloride mix without combining.

This distinction is made on the assumption that while all liquid systems of the formula xH_2O,ySO_3 are conductors, the compound SO_3HCl, as well as mixtures of its constituents, and also pure mixtures of alcohol and water, are non-conductors. In drawing this conclusion, it is, of course, assumed that we can generalise from actual observations with liquids as to their ability to co-operate in forming electrolytic circuits. The difficulty which apparently is met with in coupling carbonic oxide may conceivably arise also in the case of liquids; but it does not appear probable that such will be found to be the case, as mixtures of dielectrics, such as water and hydrogen chloride, so readily conduct a current. Of course, also, no such distinction as is above drawn can be made if pure water be slightly dissociated, as some contend it is.

In attempting to discuss these questions, however, we are entering on a field of enquiry in which, at present, we are all but strangers; we are, in fact, dealing with that remarkable class of combinations, the so-called molecular compounds, whose existence it is impossible to deny, difficult though it be to precisely define them. But that they play an all-important part in the course of chemical change there can hardly be a doubt, and it has long seemed probable to me that, as I have previously suggested, we may eventually recognise in them the mechanism through which the degradation of energy is effected in chemical changes generally.

With regard to the spontaneous occurrence of dissociation in a case such as that of sulphuric acid, it is all important probably to bear in mind that the compound represented by the formula H_2SO_4 will combine both with sulphuric anhydride, on the one hand, and with water on the other, so that a number of systems of the general formulæ xH_2O,ySO_3 are possible. There is thus an essential difference been sulphuric acid and ammonium chloride, for example, as the latter has no tendency apparently to combine with either of its constituent molecules, and, in fact, constitutes a rigid system. It may well be that it is only in cases comparable with that of sulphuric acid that dissociation occurs spontaneously without the intervention of any other substance, such systems being in the condition postulated by Fitzgerald—*i.e.*, so arranged that changes take place within them of their own accord—and being the only ones which can be formed directly from their two proximate constituents without the intervention of any third substance. The fact that liquid water itself almost unquestionably consists of a mixture of complex molecules and of fundamental molecules such as are represented by the formula H_2O must also be taken into account. In short, it would seem that a sulphuric acid water system may be likened to a complex system of springs, and ammonium chloride to a simple spring; whereas the latter can change only in one direction, and must always be in compression or extension, the former may have one part in compression and another in extension, and fluctuating changes may easily go on within it, and, in consequence, energy be gradually frittered away. Such a fluctuating system may be a necessary element in every chemical change.

It is impossible to doubt that, as a means of determining the precise character of the changes which may be going on in a complex system, the determination of the electromotive efficiency of various combinations will prove to be of the greatest importance. As a further illustration of the manner in which we may derive assistance from the introduction of such physical considerations, attention may be directed to the complex changes attending the action of metals on nitric acid, a subject which has long troubled the minds of chemists, and which has always exercised a special fascination over me. There is little, probably no hope, that we shall ever arrive at a satisfactory solution of this complex problem so long as we regard it from a purely chemical point of view.

The observations of fundamental importance which must be first taken into account in discussing such changes are those of Millon (1842), Russel (1874), and Veley (1891), showing that silver, copper, etc., are not soluble in nitric acid free from nitrous compounds. In my opinion, however, these observations cannot be regarded as proof that nitrous acid is the solvent of the metal; the conclusion to be derived from them, I think, is of a far more interesting character.

Silver has a negative heat of dissolution, the value calculated from the data given by Thomsen being (at 18deg.):

$$2Ag + 2HNO_3, aq = -51,580 \text{ gram-deg. C. units.}$$

This value, however, is reduced to −40,700 if the heat of dissolution of silver nitrate be deducted. As the reduction of nitric acid to nitric peroxide ($2HNO_3 - O = N_2O_4$, H_2O), according to Thomsen, involves an expenditure of but 10,010 units, the oxidation by *nitric acid* of the hydrogen displaced by silver dissolving in nitric acid would give 68,360 − 10,010 = 58,350 units, which is considerably in excess of the value − 51,580, and still more so if the lower value corresponding to the formation of the anhydrous salt be taken. Silver, therefore, should be easily soluble in nitric acid if this acid can act as *depolariser*. A still stronger case may be made out by considering the values for mercury and copper, as the heats of dissolution of these metals, although negative, are considerably lower than that of silver. Such facts appear to leave little room for doubt, and to justify the important conclusion that the nitrous compound is the active depolariser.

To conclude that such metals as bismuth, copper, mercury, and silver are dissolved by nitrous acid, not by nitric acid, is to attribute to nitric acid properties which would make it entirely peculiar among acids, for it appears to be a characteristic property of acids generally to dissolve metals generally whenever the conditions are such that exothermic change can occur.

It seems to me that such problems can only be treated from an electrolytic standpoint, and the fact that we do not always so treat them is evidence of a most extraordinary failure on the part of chemists to apply Faraday's teachings. Unfortunately, the physicists have also neglected this subject, having apparently left it to the chemists to discuss the changes attending the interaction of metals and acids; the result is blank ignorance of all that is fundamental with regard to such matters on the part of both chemists and physicists.

Objection has been taken to the use of the hypothesis of nascent hydrogen in explaining the effects produced with nitric acid. No doubt the conception is much misunderstood and misused, but it is, after all, a conception which cannot be put aside. Hydrogen undoubtedly is often displaced and brought into action without ever escaping from the circuit in which, and along which, it is displaced; "nascent" hydrogen, in fact, is but hydrogen in circuit, the hydrogen which is active at the surface of the plates in a Grove gas battery, or which effects reduction when condensed in charcoal, being as much "nascent" in this sense as that displaced from water, say, by sodium amalgam in presence of a reducible substance. Moreover, the "activity" of such hydrogen depends entirely on its origin. This cannot be denied in face of the fact that if in cells of the Daniell type, for example, cadmium be substituted for zinc, not only is the E.M.F. developed lower, but lower to the extent to which the heat of dissolution of cadmium in the acid used is less than that of zinc.

In dissolving metals in nitric acid we are but dealing with "cells" of the Grove type. If nitrous acid be in any way directly active as solvent of the metal, in all probability it can but act along with the nitric acid, and not to its exclusion; but it is useless to discuss this question further until we are sure

Digitized by Google

that nitrous acid actually exists, and there is much reason to doubt this. As copper is readily dissolved by diluted sulphuric acid in presence of oxygen, although insoluble in the acid alone, it is inconceivable that nitric acid should not be equally active in presence of a sufficiently active depolariser—when the conditions are such, in fact, as are secured by the presence of oxygen, together with copper and sulphuric acid, and a system is formed within which exothermic change is possible.

It appears to me to be highly probable that the active depolariser in the cases considered is *nitrogen dioxide*, and that this becomes reduced to nitrogen monoxide, which in turn is oxidised by the nitric acid. Whether these actions all take place in one circuit has yet to be determined, but it is not unlikely that such is the case, as the electromotive efficiency of the Grove cell, as determined by Thomsen, corresponds with the assumption that the nitric acid becomes reduced to nitrogen dioxide ($2NO_2,OH_2$). The dissolution of copper on such a view would be represented as follows :

$$Cu \left| \begin{matrix} NO_3H \\ NO_3H \end{matrix} \right| ONO \left| \begin{matrix} NO_3H \\ NO_3H \end{matrix} \right| Cu =$$
$$Cu \begin{matrix} NO_3 \\ NO_3 \end{matrix} \left| H_2O \right| NO_2 \begin{matrix} NO_2 \\ NO_2 \end{matrix} OH_2 \left| Cu. \right.$$

There is thus at once a great increase in the amount of nitrogen dioxide, assuming only a minute proportion to be present in the acid at the outset, and the action can therefore take place at a rapidly increasing rate, and very soon attains a maximum. As soon as the nitric acid is saturated with the dioxide this begins to escape, but, *pari passu*, the acid grows weaker, and soon the dioxide is subjected to the attack of water, whereby nitrogen monoxide is formed and also escapes, the acid being too weak to entirely reoxidise it. It is probably from this point onwards that the E.M.F. begins to fall. It is conceivable that monoxide is formed even at an earlier stage in consequence of the exhaustion of the acid at the surface of the plate, and that the E.M.F. is also influenced in this manner. In the case of metals having positive heats of dissolution the phenomena are probably far more complicated, but, as I have pointed out in discussing this question in a note on the nature of depolarisers (*Proceedings*, 1893, 148, 188), it is possible, by applying electrochemical considerations, to deduce comparatively simple explanations. In this note I have also called attention to the case of sulphuric acid as possibly analogous to that of nitric acid, inasmuch as it only undergoes reduction when the conditions are such that the presence of *sulphuric oxide* is possible—*i.e.*, that the active depolariser, when metals such as copper (which have negative heats of dissolution) are dissolved in hot, concentrated, sulphuric acid, is the oxide, not the acid itself. Divers and Shimidzu, in a paper on the action of pyrosulphuric acid on certain metals (*Trans.*, 1885, 47, 636), have contended that the trioxide acts directly ; they formulate the action as occurring between the metal and a double molecule of the oxide which they represent as sulphuryl sulphate, as in the equation

$$SO_2(SO_4)+2Ag=Ag_2SO_4+SO_2 ;$$

but such an assumption appears to be entirely unnecessary, even if it be in any way warranted by facts.

The fact that metals dissolve in solutions of perchloric acid without reducing it, may be regarded as confirmatory of the view here put forward, as there is no reason to suppose that such solutions contain a reducible oxide ; solutions of chloric acid, on the other hand, which undergo reduction by metals, are doubtless comparable with "nitrous" nitric acid.

If it be found that such contentions as these are correct, our views of the manner in which acids act will be much simplified. Whatever view be taken of electrolysis—whether or no it be dependent on the ions becoming free like the molecules of a gas—it is difficult to understand that one compound should function in several different ways in the same circuit. If nitric acid, for example, be resolved into the ions H and NO_3, and these are arranged in any form of polarised chain along the direction in which the current acts, why should the hydrogen which separates from the NO_3 ion, giving place to the metal, act otherwise on a contiguous NO_3 ion than to reproduce nitric acid? A complete "change of front" would be necessary if it were to act in any other way. A company of soldiers who in rigid mechanical obedience to the word of command perforce *face* the enemy to receive their charge, will be bayoneted only in front by those who attack in an equally mechanical manner ; if otherwise, the word of command—the direct effect of the E.M.F.—is only partially obeyed. And to say, in order to meet such an objection, that a molecule may undergo ionic disruption in several ways is to entirely confuse our conceptions in a manner which is most undesirable so long as the facts do not *compel* us to make such an assumption.

(To be continued.)

New Element.—Mr. Eugène Demarcay believes on evidence, partly chemical and partly spectroscopic, that he has discovered yet another metal among the "rare earths."

THE PHYSICAL SOCIETY.

At the ordinary meeting on April 24 Captain W. de W. Abney, president, occupied the chair.

A paper by **Mr. R. A. Lehfeld** on **"Symbolism in Thermodynamics"** was, in the absence of the author, read by the **Secretary**. In this paper the author proposed a system of about 24 separate symbols for the different quantities in thermo-dynamics.

In the discussion that followed **Prof. Silvanus Thompson** said he was not at all favourably impressed with the symbols proposed. In particular, it was becoming usual to restrict the use of Greek letters to the representation of specific quantities or angles, and the author's proposal seemed in this way a retrograde step.

Prof. Perry said he did not care for the suggested symbols.

Mr. Elder thought the author's system would be a very severe tax on the memory, for he did not make use of suffixes, as was ordinarily done, which in a great measure define the symbol to which they are attached.

Mr. Appleyard read a paper on the **"Adjustment of the Kelvin Bridge."** In a recent paper read before the society Mr. Reeves had described a modified form of Kelvin bridge, in which a double adjustment was necessary. The author proposed to employ two wires stretched side by side, with a sliding contact in connection with the galvanometer on each. These contacts are rigidly connected together, so that the segments into which one wire is divided necessarily bear to one another the same ratio as do the segments of the other wire. Hence a single adjustment is sufficient to give balance.

Mr. Reeves said that apparently the author had completely missed the object of his (the speaker's) paper ; for the object there aimed at was to make use of such sets of resistance coils as were always to be found in any laboratory. In the author's arrangement it would be necessary to carefully calibrate the two wires, and also since the resistances used must necessarily be small, to determine the resistance of the contacts.

Prof. Ayrton forwarded a communication, in which he said the author's suggestion was ingenious, but did not obviate the necessity for much of Mr. Reeves's "addition." Further, Mr. Reeves's proposal to employ ordinary resistance boxes was not made because such resistances were absolutely necessary, but because, since they were to be found in any electrical laboratory, their use saved the expense of such a wire resistance accurately calibrated as Mr. Appleyard employed.

Mr. Appleyard, in his reply, said that his instrument was designed for use in a factory, where the time saved in making a series of tests was of more importance than the cost of the instrument.

Mr. J. Frith read a paper on **"The Effect of Wave-Form on the Alternate-Current Arc."** The author finds that an arc has the power of modifying the wave-form in a circuit in which it is included. Thus, in the case of a dynamo, for which on open circuit, the curve of E.M.F. was decidedly peaked, it was found that when this dynamo was employed to feed an arc that the curve became changed to a flat-topped form It is interesting to remember that the candle-power of the arc is greater when the wave-form is flat-topped that when it is peaked. By altering the resistance in series with the arc it is possible to alter the character of the curve, for as the resistance in series with the arc increases, the arc affects the wave-form less and less. In some recent experiments, described by Dr. Fleming, a resistance of about seven ohms was used in series with the arc, so that the wave-form of the generator, which is not an efficient form, was forced on the arc. In practice, however, where a resistance is not used in series with the arc, this is not the case, and the differences between the efficiency obtained for alternate-current arcs in the laboratory and that claimed in practice may thus be accounted for.

Mr. Blakesley said it seemed as if the more nearly the alternate current resembled a direct current—*i.e.*, the longer in each period the current remained constant—the greater was the efficiency of the arc

Mr. Price asked what was the cause of the reaction of the arc on the wave-form

Mr. Tremlitt Carter asked whether previous observers' results were vitiated by this action of the arc on the wave-form?

Prof. Ayrton, in a communication forwarded, said the author's suggestion was of great importance as bearing on the question of the efficiency of the alternate-current arc.

Prof. S. P. Thompson said that the dynamo employed by the author was one in which there was a large quantity of iron in the armature, so that the self-induction was large. Was it not on account of this large coefficient of self-induction, which would tend to keep the current constant, that the arc was able to alter the wave curve? If an arc was connected to the mains of a supply station in which a number of machines in parallel were feeding a number of lamps, would the arc still be able to affect the wave-form of the current?

Mr. Tremlitt Carter asked if the author had tried the effect of replacing the arc by a resistance such that it would absorb the same volts as did the arc, and comparing the curves for the current and impressed P.D. with those obtained with the arc.

The **Author**, in his reply, said that the effect of the self-induction of the machine was shown in the curves. Current curves had not been taken with the arc straight on the machine. The current and self-induction were the same for all the curves, the voltage of the machine being increased by increasing the field when resistance was placed in series with the arc. When, as was commonly the case, special machines were used to supply arcs, and

Digitized by Google

the load consisted solely of arcs, the arcs could alter the character of the wave-form. If the arc was replaced by a resistance, the wave-form was of the same type as was obtained for the E.M.F. of the machine on open circuit.

The society then adjourned till May 8.

ELECTRIC LIGHTING EXTENSIONS IN ISLINGTON.

The following is the report which Mr. Gay, the electrical engineer to the Vestry, has prepared on the suggested extensions of the electric lighting in the parish:

In accordance with your instructions, I have gone carefully into the cost of extending the mains on both sides of the Caledonian-road, Camden-road, Essex-road, and the completion of the Holloway-road from the Nag's Head public house to the Archway Tavern. This includes pipes and mains for the street-lighting in all cases, lamp columns, lamps and fittings and all accessories, as well as labour and relaying. The cost of this for the different streets is as follows:

Caledonian-road	£8,796
Camden-road	4,035
Essex-road	6,549
Holloway-road	4,914
Total mains	£24,294

As we have already a large number of lamps applied for that we cannot connect to our present plant, I do not think it would be wise to put in anything less than two 300 kilowat alternators and two 500-h.p. engines, thus rather more than doubling the working capacity of the station. This I think will be absolutely necessary for the autumn. The total estimated cost of engines, alternators, boilers, etc, is as follows:

Two 300-kilowatt alternators, two exciters, and accessories, say	£5,000
Four Lancashire boilers and accessories, say	2,750
Two 500-h.p. engines and accessories, say	6,000
Contingencies, steam-pipes, etc., say	1,500
Meters, transformers, low-tension mains, and accessories, say	3,000
Total	£42,544
Extension of buildings, in accordance with architect's estimate	5,500
Grand total of	£48,044

This is a most serious increase, and, as you will see, is more than half made up of mains a very large proportion of which I fear will be comparatively unproductive for some time to come

As I have already stated, the machinery more than doubles the capacity of the station, the actual figures being:

Present total capacity	500	kilowatts
Available after allowing reserve	375	kilowatts
Proposed extension	600	kilowatts
Total	1,100	kilowatts

of which, after allowing reserve, 800 kilowatts will be available, as against 375 available now.

The extension will enable us to run, roughly, 21 000 35 watt lamps at one time, after allowing for full reserve.

Considering the large demand we have in the present district, and which ought to increase very much towards the autumn, I do not feel justified in recommending the committee to lay out such a large sum upon mains in districts where the demand is problematical, and I should be glad if the committee would reconsider this question, as far as the extension of mains is concerned.

Mains are laid at the present time along seven miles of frontage, and the new mains are equivalent to a further 10 miles of frontage, or a total laying of 17 miles within 12 months of the opening of the works, supposing that this scheme is carried out. This, I venture to think, represents a much greater distribution than is justified within the period. Such an immense outlay for additional mains must seriously delay the date at which the department becomes profitable, and I think it would be wiser to see the result of a complete year's working before a further £25 000 is expended for new mains. In any case, I would respectfully suggest that the question of the extension of mains be considered separately to that of the plant, which is absolutely necessary, and if placed on order this month could not possibly be ready before October.

KINGSTON-UPON-THAMES.

The following is the second annual report of Mr. J. E. Edgcome, A.M.I.M.E., borough electrical engineer, to the Lighting Committee of the Corporation upon the working of the electricity undertaking of the borough:

Machinery.—Since the last report a Reeves patent filter has been fitted in the boiler-house for the purpose of extracting the oil from the condensed water before returning it to the boilers. A Maignen water-softening plant has been erected near the boiler-house for the purpose of softening and purifying the raw feed water taken from the river, in order to avoid any future trouble from scale forming in the boilers. A second coal-shoot has been laid down behind the works, so that a stock of coal of 100 tons can be kept in hand in case of strikes or other unforeseen circumstances interfering with the delivery of fuel.

Launch Charging.—The arrangements for launch charging will be completed within a month, and a supply of current for electric launches will be available from the works during the boating season.

Mains.—A number of cable extensions have been carried out, the mains having been laid, for the purpose of connecting fresh consumers, to Kingston-hill, Manorgate-road, Cambridge-road, Fassett-road, Grove-crescent and Lingfield avenue. The two sub-stations in London-street and the Horsefair have been completed and equipped with transformers and high and low tension switch and fuse gear, and connected to the low-tension mains. An extra 25-kilowatt transformer, with switch and fuse gear, has been placed in the sub-station under the town hall Further low-tension mains have been laid in Thames-street, so that that thoroughfare has now distributing mains equal to ·6 square inch, and capable of supplying current to 1,800 8-c.p. lamps. A service main has been laid to the sewage works, which are now lighted electrically throughout The labouring-class dwellings built by the Corporation in Pheasant-lane are also lighted electrically. The number of consumers has increased from 77 at the end of 1894 to 99 on December 31, 1895, on which date the number of lamps installed was equal to 4,800 of 8 c.p.

Works Expenditure and Receipts.—The figures given in the following tables are for a period of 12 months from January 1 to December 31, 1895.

ELECTRICITY SUPPLIED.

Quarter ending	Units.	Electricity.	Meter rents.
March 31, 1895	18,962	£468 4 1	£14 9 0
June 30, 1895	9,410¼	232 16 10	15 7 6

LEGAL INTELLIGENCE.

COMPETING COMPANIES.

At the Westminster County Court on Wednesday, before his Honour Judge Lumley Smith, Q.C., the case of the London Electric Supply Corporation *v.* Prentice came on.

This was an action on the part of the plaintiff company to recover the sum of £15, being £10 for breach of contract and £5 in respect of work done on behalf of the defendant at his private house, 60, Park-street, W.

It appeared from the opening statement of counsel that in February last the plaintiffs, through their canvasser, obtained from the defendant a contract in writing to supply electric light to his house in Park-street, but a few days after the contract was signed the defendant wrote a letter of repudiation on the ground that he had made an error in signing the contract with the plaintiff instead of with the Westminster Electric Supply Corporation.

Mr. Carter, chief clerk in the employ of the plaintiff firm, said the defendant then signed the contract for a year's supply of light, but a few days afterwards he repudiated it on the ground that he intended to make the contract, not with the plaintiffs, but with the Westminster Company.

The **Plaintiffs' Canvasser** was called, and said he had on several occasions called upon the defendant in respect of the installation of the electric light. He was aware that the Westminster Company had previously supplied the house with light, but he took the order quite in the usual way.

For the defence it was contended that the contract was signed under a misapprehension, and that the defendant intended to give the order to the Westminster Company, who had supplied the light previously.

The **Defendant** and his **Clerk** were both called, and gave evidence to this effect.

After hearing further evidence at some length, his **Honour** said the Westminster Company appeared to have acted as well as any company could act in the matter. He (the Judge) was quite convinced that the contract with the plaintiff had been signed in error, and could not be enforced; therefore judgment would be for the defendant, with costs.

ACTION AGAINST THE SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

In the Chancery Division of the High Court of Justice on April 25 Mr. Justice Romer had before him the case of the Electric Construction Corporation, Limited *v.* the South Staffordshire Tramways Company, who sought to recover certain sums due upon an agreement entered into between the parties in February, 1892.

Mr. Eve, Q.C., and Mr. Theobald appeared for the plaintiff corporation; and Sir F. Lockwood, Q.C., Mr. Oswald, Q.C., Mr. Jenkins, and Mr. T. D. Muuns appeared for the defendants.

Mr. Eve, in opening the case, said a number of defences, or amended defences, had been put in, and the last of them practically came to this: that the agreement was under circumstances so capable of fraud that no court would enforce specific performance. The defendants counterclaimed, setting up that the agreement was not binding on them, asking for rescission and damages. The defendant company was incorporated under a special Act in 1889 for the purpose of acquiring the assets and liabilities of a limited company which was incorporated early in the eighties for the constructing, working, and maintaining certain tramways in Staffordshire. Under further orders further tramways were constructed, and the limited company was dissolved by Clause 4, Section 13, of the Act. Having obtained that Act in August, 1889, it became necessary for the company to set about seeing what form of motive power they should substitute for the steam power. At this time there had been introduced by various companies and firms a system of working tramways by means of overhead electrical works and other electrical appliances, and on October 17, 1889, at a Board meeting of the company, held at Darlaston, it was agreed to invite tenders for the supply of traction power and maintenance. In May, 1889, a company was registered for the purpose of introducing a system of electrical working into this country, and that was the first-named plaintiff company in the action. Mr. Joseph Smith was the managing director, and he subsequently changed his name to Ebbsmith, being known as Mr. Joseph Ebbsmith. The works director was Mr. Thomas Parker and the engineering adviser of the company was Mr. Carruthers Wain. By one of the many amended defences it was suggested that this company was got up for the purpose of foisting the undertaking on the defendant company, or, so to speak, in order to bleed the defendant company in the matter of the traction part of the undertaking. One of the equities relied upon against the plaintiff company was that Mr. Spencer Balfour was a founder of the company, and that Mr. C. Wain occupied a like position. The company having been floated went on its way, and it was not until something like 18 months after the first suggestion that the defendant company should look out for someone who would supply electricity that the two companies were brought together, and the negotiations were commenced that ultimately resulted in the agreement of February, 1892. In March, 1895, the plaintiffs, under a clause in the agreement, elected to determine, and if the notices given were valid, then the plaintiffs were entitled to the sums they sued for, and for a declaration that they were entitled to determine the agreement. He asked for an account of what was due in respect of the mileage during the working of the tramways, that they were entitled to determine the contract, that they were no longer bound by Clause 8 of the contract, which provided that for a period of five years they should manage the work, and inasmuch as the mileage for five years on 250,000 was a portion of the price payable to the plaintiffs, and by reason of the determination of the contract they were not able to receive that price, they asked for the difference between the actual mileage run and the minimum mileage in five years—namely, £13,186, being 4½d. per mile. The defendants' answer to that was that the agreement was over-reaching and ought to be set aside, in respect to which they counterclaimed.

Evidence was then called in support of the plaintiffs' case

Sir Frank Lockwood, Q.C., opened the defence, and said that his contention would be that in the negotiations which led up to the contract of February 26, 1892, the interests of the South Staffordshire Company were betrayed and the interests of the plaintiff company ignored. The view he presented to the Court was that, so far as the plaintiff and the defendant companies were concerned, the beneficial nature of this contract to either of them was absolutely ignored, and the only object was to capture the South Staffordshire Tramways Company and its advantageous concessions. What he had to do was to satisfy the Court that in the negotiations for the contract the interests of the company were not only betrayed by those who were representing it, but the interests of the plaintiff company were entrusted to one who knew perfectly well how the South Staffordshire Company was being treated. After giving a history of these proceedings, and of the mode in which the plaintiff company was formed and the contract made, the learned counsel submitted that if he established that the contract was oppressive, and that the company could not survive under it, then the plaintiff company must fail, and he was entitled to rescission of the contract.

The judgment and evidence in the former trial were then put in and read, and evidence called for the defence.

The hearing of the case, which had already occupied three days, was adjourned until yesterday (Thursday), and had not concluded at the time of our going to press.

COMPANIES' MEETINGS AND REPORTS.

INDO EUROPEAN TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held on April 29 at Winchester House, Mr. J. H. Tritton presiding.

The **Chairman,** in moving the adoption of the report, said the past year had been a quiet one, and they had, fortunately, to deal with a satisfactory revenue. Their receipts for 1895 amounted to £123,734, an increase on the previous year of £4,616. They owed this increase to the trans-Indian business, and they owed that, again, to the discoveries of gold in Australia. With respect to India, their trade was pretty much where it was before. There was a slight increase, but the income derived from the traffic had not made up the leeway which set in with the reduction of rates made in the year 1886. The code tariff over their wires India took rank amongst the lowest tariffs in the world, and for each hundred miles of line was so very much less than the charge made, for instance, over the Post Office wires in this country as to be beyond all reasonable comparison. Their expenses in 1895 under all heads were £67,820, exceeding by £2,981 those of 1894 After deducting these expenses, the interim dividend paid, and the amount placed to reserve, the directors were enabled to recommend a final dividend and bonus making a total distribution for the year of 10 per cent.

Major-General G. B. Tremenheere seconded the motion, and the report was unanimously adopted.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held on April 29 at Winchester House, the Marquis of Tweeddale presiding.

The **Chairman,** in proposing the adoption of the report and the payment of a dividend of 2s. 6d. a share and a bonus of 4s. a share, making, with previous distributions, 7 per cent. for the year, stated that the gross receipts for the half-year to December 31 last had been £311,582. or an increase of 50,260 over those of the corresponding period of 1894. This increase was mainly due to the exceptionally heavy traffic exchanged with Western Australia in connection with the gold-mining industry, which had so largely developed in that colony. All gold-mining, however, being more or less speculative, they must not reckon upon a continuance of these abnormal conditions. The working expenses of the half-year had been £84,044, or a decrease of £5,696, owing to the cost of cable repairs having been much lighter during the past half-year than during the same period of 1894. Comparing the figures of the whole year, the gross receipts for 1895 had been £575,722 (the largest amount they had ever earned), being an increase over the receipts of the year 1894 of £66 719. The working expenses for the same period exhibited an increase of £9,263, but this was accounted for by the cable repairs being unusually heavy during the first half of 1895, while several exceptional items also came into last year's accounts The fire insurance fund had been credited with £20,000 from the revenue account, thus increasing it to £26,159, which must be still further added to. After paying the dividend and bonus recommended, there

Digitized by Google

was a balance of £129,329, which had been carried to the general reserve fund, which now stood at £561,546, after debiting the fund with the balance of the cost of the alternative Singapore-Hongkong cable and the cable renewals effected during the half-year. At present all the cables were in good working order, but he believed that that was the first occasion on which this statement had been made. The directors had decided to revise the local tariffs on July 1 by placing them on a more uniform and satisfactory footing. These reductions were expected to result in a considerable loss of revenue at first—possibly at the rate of £40,000 per annum—but it was hoped that the loss might eventually be recouped by growth of traffic.

The motion was seconded by **Mr. F. A. Bevan** and carried unanimously.

Great regret was expressed at the illness of Sir John Pender, the chairman of the Company.

HASTINGS ELECTRIC LIGHT COMPANY.

The annual meeting of the Hastings Electric Light Company was held at the Queen's Hotel, Hastings, on April 24. The directors present were Messrs. F. A. Langham (chairman), F. Noakes, F. J. Parsons, J. Reeves, sen., J. Woodhams, and A. L. Ward, and there was a good attendance of shareholders.

The **Chairman**, in moving the adoption of the report, expressed regret at the character of the report, but said there were good prospects. Their increase on the receipts of lighting amounted to the sum of £1,302. At the end of 1893 the lamps were equal to 8 c.p., and they had 5,446 lights. In 1894 they had 6,434, and last year they increased to 8,199. The increase on the lighting revenue was £1 302, and the cost of production in 1894 was £2,234. 5s. 2d.; and in 1895, £3 226. 5s. 3d., an increase of £892. 0s 1d. The sum paid for distribution of electricity in 1894 was £219. 4s. 11d., whilst last year it was only £82 14s. 5d., a decrease of £126. 10s. 6d. The cost of public lamps came to £327. 19s 11d., as against £431 2s. 9d., or a saving of £103 2s. 10d. The rates and taxes, he was sorry to say, were £59. 16s. 10d higher than in 1894. The management expenses were £591 1s 2d., as compared with £740. 18s. 10d , a decrease of £149. 17s 8d. The law charges were £137. 9s. 2d. more last year than in 1894, but he would explain that later, whilst the special charges showed an increase of £354. 17s. 9d. This left them a net increase of income of £237. 7s. 2d. This included the bad debts and law charges, the latter of which were a heavy amount this year, caused by the arrangement for the new premises and additional warehouses. They could not carry on the business of the electric lighting without the sanction of the ground landlords of the Cornwallis Estate, who wanted them to surrender their old lease and take a new one, and other things Of course, these charges would not occur again, nor would the £355. 18s. 3d. for bad debts. He was not sure that the new system of the sale of current benefited either the Company or the consumers. Large consumers might derive benefit, but to get the full advantage electricity should be as liberally used as gas. To use both meant that they would very probably pay more for both, but the more electricity they used the cheaper it got. He was sorry that the public lighting had been a great burden to the Company, and had ended in an absolute loss. They had fulfilled their contract to light the Front at a very low sum, and the loss on this account, coupled with the expenses necessary for lighting, meant quite sufficient to pay a dividend. Until they could get rid of the contract, or get better terms, the Company could not be in a flourishing condition. The directors were considering what price they should charge the Corporation for the light. If they did not wish to continue, the Corporation was bound to buy the fittings and wires at a valuation, so that the shareholders would get some of their money back. They had enough private incandescent lighting to supply to keep them busy.

Mr. H. G. Shorter seconded the motion, and the report was unanimously adopted.

Messrs. Noakes and Parsons were re-elected directors.

CONTINENTAL METROPOLITAN TRAMWAYS COMPANY, LIMITED.

The ordinary general meeting of the shareholders was held at the Cannon-street Hotel on April 24, Mr. B. H. Van Tromp presiding.

The **Chairman** stated that they had expressed their willingness to adopt mechanical traction in Paris in return for an extension of the concession giving the company 30 years' longer life, but it was evident that the town of Paris was not willing to entertain such a proposal. That being so, they had asked the town for a subsidy of £16,000 a year for 14 years to get over the difficulty of amortisation. If this proposal were accepted, they felt that they would be justified in taking the necessary steps for making the change in the method of traction.

The report was unanimously adopted.

ELMORE'S GERMAN AND AUSTRO HUNGARIAN METAL COMPANY, LIMITED.

The fifth annual meeting was held on Monday at Winchester House, Mr. John M'Farlan presiding.

The **Chairman**, in moving the adoption of the report, stated that the accounts showed a satisfactory state of affairs. The trading account showed a considerable improvement over that of 1894. The sales were more than double, while the amount spent on manufacturing, purchases, and wages, after deducting copper, was not very much larger than in 1894. Although the improvement in sales was large, it was not so great as was expected, but they had had serious and unexpected difficulties to meet. In 1893 the amount of work done was of the value of £3,194; in 1894, £8,130; and in 1895, £17,025 As to the present year, the sales up to the 19th April had been 59¾ tons, of the value of £5,648, as compared with 40¾ tons, of the value of £3,706, last year. The Board admitted that from a shareholder's point of view progress had been slow and disappointments grievous, but these were always encountered in the working out of any new invention. Now that every technical difficulty in working had been overcome it was felt essential that the business should be conducted on a large scale, and to carry out the extensions considered necessary £25,000 would be required.

Mr. John Heal seconded the motion, which was carried unanimously.

The retiring director (Mr. Heal) and the auditors (Messrs. Cooper Bros. and Co) were re-elected.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague Application should be made to the Stadrath, Prague.

Peneranda de Bracamonte.—Tenders for electric lighting of the town for a period of 15 years may be sent to the authorities at the Casa Consistoria, Peneranda de Bracamonte, Spain, by May 28.

Bruges.—Tenders are wanted by May 13 for the supply and erection of an electric water-level indicator for the River Lys. Particulars from Le Gouvernement Provincial, Bruges, Belgium.

Stralsund (Germany).—Tenders are invited for installing the electric light on a steamer. Particulars for 1·50 marks (1s. 6d.) from the Werftbureau, Konigl. Wasser-Bauinspection, Stralsund.

Chapelle-lez-Herlaimont.—Tenders are wanted by May 15 for erecting three lightning conductors on the Hôtel Communal. Address, M. le Bourgmestre, Chappelle-lez-Herlaimont, Belgium.

Spezzia (Italy).—Tenders are wanted by May 11 by the Torpedo and Electric Department at the Spezzia Arsenal and Dockyard for the supply of a quantity of copper and brass in wire sheets, and nails, etc.

Frankfort-on-the-Main.—Tenders are wanted by May 9 for the supply of telegraph posts for the Government railways. Address, Konigl. Eisenbahn-Telegrapheninspection, Frankfurt-a-M., Germany.

Oldham.—Tenders are wanted by May 12 for an engine and dynamo of 360 h.p. from makers only who have previously constructed dynamos of that size. Particulars of Mr. A. Andrew, Gas and Water Offices, Oldham.

Hammersmith (London).—The Vestry want tenders by May 27 for (*a*) high and low pressure cables, (*b*) arc lamps and posts, (*c*) transformers, (*d*) an overhead travelling crane. Particulars from Mr. A. H. Preece, 39, Victoria-street, Westminster, on a deposit of two guineas.

Paris.—Tenders will be received by the Prefect of the Seine at the Paris Tribunal de Commerce on May 23 for the installation and working for 10 years of the electric light at the Hospice de Brévannes. The estimate is about £5,533, and the maximum annual payment 27,000f. (about £108).

Bray (Ireland).—The Town Council want tenders by May 17 for (1) a steam alternator, 75 kilowatts; (2) a Lancashire boiler, 200 h.p.; (3) economiser and feed-pump; (4) a vertical high-speed engine. Specifications, etc., can be obtained from Mr. P. MacDonnell, town clerk's office, Town Hall, Bray, on deposit of two guineas.

Lisbon.—Tenders are wanted by the Royal Portuguese Railway Company for the supply of articles and material necessary for the upkeep of their electric lighting. Tenders must be sent to the chief engineer, at the company's stores at Santa Apolonia Station, Lisbon, by May 6, and particulars can be obtained there, or at the company's Paris offices, Rue de Châteaudun 28.

Kingston-upon-Thames.—Tenders are required by the Corporation for the supply of coal for the electric works for the year ending July 1, 1897. Conditions and forms of tender can be obtained at the town clerk's office, Clattern House, Kingston-upon-Thames. Sealed tenders, endorsed "Coal," to be delivered by 7th inst. Mr. Harold A. Winser, town clerk.

Wakefield.—Tenders are invited for the construction and erection of Contract No. 2, electric lighting buildings, etc., at Calder Vale, Wakefield, for the Council. Plans and specification may be seen and bill of quantities and form of tender obtained (on payment of £1. 1s., to be returned on receipt of bona fide tender) at the office of Mr. R. Porter, city surveyor, Town Hall, Wakefield. Tenders for the whole of the works, or for the works comprised in each separate trade, addressed to the Town Clerk, Town Hall, Wakefield, to be delivered by 13th inst., endorsed "Tender for Contract No. 2."

St. Helier (Jersey).—Persons wishing to establish a lighting station in the locality for the purpose of supplying electric, gas, or other forms of light, for both public and private use, are requested to communicate with Mr. P. Baudains, constable, Town Hall, St. Helier, Jersey. All such preliminary communications

Digitized by Google

are to state (1) form of light—*i.e.*, whether electric, gas, etc.; (2) in the case of electric light, what methods of generation and distribution would be adopted; (3) proportionate price for public purposes and private lighting; (4) general conditions under which tenders would be made. All necessary information will be supplied on application.

Coventry.—The Electric Lighting Committee require tenders for the supply and erection of the following plant: (Section A) boiler-house plant—boilers and fittings, mechanical stokers and economiser, feed pump, etc.; (Section B) engine-house plant—steam-engine, alternator, oil filter, fittings, etc., steam, exhaust, feed blow-off, sundry pipes, valves, etc. Tenderers are at liberty to tender for either section but not for part of a section The ground plan of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation Ormond House, Great Trinity-lane, London, E.C., on and after 24th inst. on payment of £2. 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to Mr. Lewis Beard, town clerk, St. Mary's Hall, Coventry, and delivered by May 12

Shooter's Hill (London).—Tenders are wanted by May 6 for the provision and fixing of electric bells, telephones, fire alarms, etc., at the Brook Fever Hospital, Shooter's Hill, S.E., for the Metropolitan Asylums Board. Copies of the specification form of tender, conditions of contract, and of the drawing, which have been prepared by Prof. Kennedy, LL D., F.R S., of 14, Old Queen-street Westminster, S.W., can be obtained at the chief offices of the Board on and after 16th inst. upon depositing gold or Bank of England note to the value of £5 (which will be returned only to those who send in a bona fide tender in accordance with the terms of this advertisement, and who return the drawing, specification, and conditions of contract). Tenders, which will only be received on the lithographed form supplied by the Board, must be sealed and endorsed "Tender for Electric Bells, Telephones, etc, Brook Hospital," and must be delivered at the Chief Offices, Norfolk House Norfolk-street, W.C., by 2 p m. on May 6. Unless the tender be accompanied by the specification, conditions of contract, and the drawing it will not be considered.

RESULTS OF TENDERS.

Birmingham.—The Birmingham Electric Supply Company, Limited, have got the contract for wiring and fitting the new general hospital.

Edinburgh.—The tender of Messrs. Lowden Bros, at £188, for wiring the City Chambers for the electric light, for the Corporation, has been accepted.

Elberfeld.—For electric lighting installations at the Elberfeld and Barmen stations of the Prussian State Railways on April 20, the lowest tenders were as follows: for the whole installation at Elberfeld, including the steam-engines, the Helios Aktien-Gesellschaft, Köln-Ehrenfeld, 86,920 marks; for ditto at Barmen, the Elektricitäts Aktien-Gesells. vorm. W. Lahmeyer und Cie., Frankfurt-a-M., 61,204 marks. Twenty-four firms tendered, but some of these were for the engines only. No English firm tendered.

London, N.—The following tenders were received for electric lighting at the Northern Polytechnic Institute, Islington:

A. Fearnhead	£1,027
Strode and Co.	419
Crompton and Co.	407
Faraday and Son	340
Vaughan and Brown	266
Wenham and Waters	245
Russell and Lennard (accepted)	219

Bedford.—For the construction in various positions in the borough of five electric light underground sub-stations, for the Bedford Urban Sanitary Authority, the following tenders were received:

T. H. Coleman (accepted)	£235 0 0
G. E. Fathers	272 10 0
T. Laughton	295 0 0
J. P. White	325 0 0

All of Bedford.

Bedford.—The Electric Light Committee received the following tenders for the supply and erection of the following plant: (Section A) one 240 b.h p. double-acting compound enclosed engine, (B) one 150-unit alternator with stationary armature:

Engine and alternator.

S. Z. de Ferranti	£2,350
Brush Electrical Engineering Company	2,253
D. Stewart and Co.	2,195

Alternator only.

Siemens Bros. and Co.	1,250
Fowler and Co., Leeds	1,090
Crompton and Co.	980
Mather and Platt	930
Manchester Edison-Swan Company	928
Electrical Construction Company	903
Johnson and Phillips	850
Easton, Anderson, and Goolden (accepted)	654

Engine only.

Belliss and Co.	1,050
Sissons and Co.	790
W. H. Allen, Son, and Co. (accepted)	700

Cardiff.—The following tenders were received by the Corporation for the construction, supply, delivery, and fixing of two boilers of the dry-back marine or water-tube type, each to evaporate about 6,000lb. of water per hour, and one 250 to 300 kilowatt direct-driven steam alternator:

Engine and alternator.

Electrical Construction Company, Peache engine, E.C.C. alternator, 250 k.w., speed 350	£2,493 0 0
Brush Company, Raworth engine, Mordey alternator, 300 k.w., speed 266	2,668 0 0
Crompton and Co., Peache engine, Crompton-Brunton alternator, 300 k.w.	2,770 0 0
Electrical Construction Company, Pollitt and Wigzell engine, E.C.C. alternator, 300 k.w., speed 127	2,970 0 0
Crompton and Co., Willans engine, Crompton-Brunton alternator, 300 k.w.	3,015 0 0
Crompton and Co., Belliss engine, Crompton-Brunton alternator, 300 k.w.	3,051 0 0
Ferranti and Co., Ferranti engine, flywheel alternator, 300 k.w., speed 200 (accepted)	3,250 0 0
Johnson and Phillips, Belliss engine, J. and P. alternator, 300 k.w., speed 300	3,350 0 0
Siemens Bros., Belliss engine, Siemens alternator, 300 k.w., speed 300	3,360 0 0
Electrical Construction Company, Belliss engine, E.C.C. alternator, 300 k.w., speed 300	3,407 0 0
Ferranti and Co., Belliss engine, flywheel alternator, 300 k.w., speed 350	3,500 0 0
Siemens Bros., Willans engine, Siemens alternator, 300 k.w., speed 267	3,740 0 0
Easton, Anderson, and Goolden, Corliss engine, patent alternator, 300 k.w., speed 120	4,100 0 0

Boilers.

E Danks, Birmingham, dry-back marine boiler (accepted)	767 10 0
J. Thompson, Wolverhampton, Economic	890 0 0
Fraser and Sons, Limited, London, dry-back marine	974 0 0
G. Sinclair, Leith, dry-back marine	990 0 0
Davey, Paxman, and Co., Economic	998 0 0
Crompton and Co., Economic	1,028 0 0
Tinkers, Limited, dry-back marine	1,060 0 0
Fleming and Fergusson, Clyde water-tube patent	1,079 0 0
Lindsay, Burnet, and Co., dry-back marine	1,095 0 0
Hawkesley, Wild, and Co., dry-back marine	1,100 0 0
Babcock and Wilcox, water-tube	1,100 0 0
Fleming and Fergusson, dry-back marine	1,110 0 0
Abbott and Co., dry-back marine	1,150 0 0
Electric Construction Company, dry-back marine	1,155 0 0
Hornsby and Co., dry-back marine	1,400 0 0
J. Brown and Co., Scotch marine, with patent draught, etc.	3,700 0 0

BUSINESS NOTES.

Leith.—The ratepayers want to amalgamate with Edinburgh so as to share in the electric light.

Cheltenham.—The estimate for street electric lighting during the ensuing year amounts to £280.

Hull.—The borough engineer has been instructed to report on the various systems of electric traction in use.

Morley.—The Corporation have applied to the Board of Trade for a license for an installation of electric light.

Hampstead (London).—In order to save time, the Electric Lighting Committee is to report on the tenders received for a new alternator.

Dover.—The Corporation Tramways Order has been advertised prior to its being introduced in a confirmation Bill. Electric or cable power will be used.

Edinburgh.—The Electric Lighting Committee have resolved to reduce the charge per unit to 5d. from May 15 next, to fix the rate for public lamps at £18 each per annum, and to discontinue meter rates.

The Great Wheel.—Messrs. Foote and Milne, electrical engineers, have carried out a novel form of advertisement at Earl's Court by illuminating great letters on the rims of the wheel with electric lamps.

Catalogue.—We have received an interesting catalogue of electric light fittings from Messrs. F. and C. Osler, 100, Oxford-street, W. Owing to want of space, we are compelled to hold over our notice till next week.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending April 26 amounted to £1,168, as compared with £1,121 in the corresponding week of the previous year, being an increase of £471.

Eastern Extension Telegraph Company.—The *Times* correspondent at Simla says that the cotton trade between Bombay and Japan, which is yearly growing in importance, is greatly handicapped by the high rates for cablegrams charged by the Eastern Extension Company.

Brighouse.—Mr. Brook, the owner of the plant at present supplying the electric light in the borough, has offered, through Mr. Furniss, solicitor, to sell the plant to the Corporation, and a sub-committee of the Gas Committee has been appointed to obtain the terms and conditions of sale.

Liverpool.—A Board of Trade enquiry has been held into the application of the Liverpool District Electric Lighting Company for an order empowering them to supply electricity in the districts of

Digitized by Google

Garston and Much Woolton, the Urban District Councils of which had no objection to the granting of the order.

Hanley.—At a meeting of the Town Council the General Purposes Committee reported that the British Insulated Wire Company had offered to supply the twin cable, ceiling roses, and other fittings for the two park lodges free of cost, and the committee recommend that this offer be gratefully accepted. The report was adopted.

Tunbridge Wells. — The enlargement of the electric light station has been commenced and the foundations have been got in this week. In view of the approaching Royal visit, the borough electrical engineer is arranging for electric illuminations for the evening in connection with the decorations which are being organised.

City and South London Railway.—The returns for the week ended April 26 were £889, compared with £900 for the corresponding period of last year, being a decrease of £11. The total receipts for the half-year terminating as above were £16,149, compared with £16,119 in the same period of the preceding year, being an increase of £30.

Glasgow.—The members of the sub-committee on mechanical tramway traction have decided before making any report to the Tramways Committee or to the Corporation. and before entering upon consideration of the report by Messrs. Crawford and Young, to visit Coventry, Bristol, and Hamburg, and inspect the electric tramways in these places.

City and South London Railway Bill.—The City and South London Railway Bill was read a second time last Friday, and the committee to which the Bill was referred was instructed to consider whether any provisions can be made for the preservation of the Church of St. Mary Woolnoth without preventing the construction of the railway and station.

Cleckheaton.—At the general meeting of the Co-operative Society a prolonged and animated discussion ensued on the question of lighting up the Central Stores with electricity. The estimated cost of the installation was stated at £800 to £1,200 and 50 votes were recorded in favour of electricity to 51 against. Consequently the proposal was defeated.

Chatham.—At the meeting of the Town Council the Highway and Works Committee reported a complaint from the electric lighting company as to the Corporation workmen having damaged one of their mains. This arose from a complaint by the Corporation that the electric lighting company had taken up the footway without first giving notice. The company, however, pleaded emergency. The surveyor was instructed to enquire into the matter.

Dalkey.—At a meeting of the Town Commissioners a letter was read from Messrs. M'Loughlin and Garland, solicitors, enclosing a copy of counsel's opinion with reference to the electric tramways company and the state of the township roads Counsel advised that proceedings should be taken to compel the company to put the roads and footpaths in order. The Chairman suggested that the consideration of the matter should be postponed, and the suggestion was adopted.

Blackpool.—A Local Government Board enquiry has been held into the application of the Corporation for permission to borrow a sum of £30,000 for electric lighting purposes. It was stated by the electrical engineer that a further extension of the works was urgently need. There was at present a demand for current which could not be supplied, and unless new plant was put down for the summer season the committee in charge of the works would not be able to fulfil its obligations.

Appointments Vacant.—The Shoreditch Vestry require a resident electrical engineer to take charge, under the Vestry's consulting engineers, of the laying of mains and the erection of electrical and steam machinery for central stations, for a minimum period of four months, at a salary of £4 per week. Applications, on forms provided, with copies of two recent testimonials, to be sent to Mr. H. Mansfield Robinson, vestry clerk, Town Hall, Old-street, E.C., by 4 p.m. on 11th inst.

Dublin.—The Pembroke Commissioners have held a special meeting to consider, under the provisions of the Tramways Acts, the Rathmines, Dundrum, and Blackrock district tramways scheme, and having heard what was alleged on behalf of the promoters, they disapproved of the project, on the ground that the statutory requirements of the Tramways Acts have not been complied with, that the deposited plans are defective, and that the company proposing to work the line have practically no capital subscribed.

Western and Brazilian Telegraph Company.—After placing £3,000 to the reserve fund and £7,952 to the debenture redemption fund. the directors propose a balance dividend of 5s. 3d. per share on the ordinary shares, making 3 per cent. for the year ended December 31 last. The preferred ordinary shares are to receive 3s. 9d and the deferred ordinary 1s. 6d. The receipts for the week ending April 24, after deducting 17 per cent. payable to the London Platino-Brazilian Telegraph Company. amounted to £2,648.

Haslingden.—At a special meeting of the Industrial Co-operative Society it was resolved to light the four front shops of the society with electricity. From a statement by the manager (Mr. H. Ashworth) it appeared that the Wholesale Society's engineer estimated that by trebling the consumption of gas in speeding up the present engine sufficient electricity could be generated for the four shops, providing 89 16-c.p. incandescent lights. The installation would cost £470, and there should be a saving of 10 per cent. on the outlay.

Central London Railway Company.—The hearing of the case of the Kensington Woodhouse Park Syndicate *v.* the Central London Railway occupied Mr. Under-Sheriff Burchell and a special jury at the London Sheriff's Court for four days. The claim was for £28,000 as compensation for the compulsory acquirement by the respondents of an estate known as Woodhouse Park, Shepherd's Bush. The jury found a verdict for £4,500, to which 10 per cent. was added for compulsory purchase, making the total compensation £4,950.

Bolton.—The members of the Joint Committee of the Streets and Electricity Committee have under consideration the report prepared by the borough surveyor (Mr. Brockbank) and the former borough electrician (Mr. J. H. Rider, M.I E E.) on the application of electricity (overhead wire system) to the tramways. A deputatation has visited Bristol and Walsall to inspect the systems there in vogue. The deputation were met at Bristol by Mr. Rider, who has commenced his duties as borough electrician at Plymouth, and explained the system on the four miles length, from the old Market-place, Bristol, to Kingswood.

Dewsbury.—A meeting of the governors of the Technical Institute has been held for the purpose of receiving a further report from a committee specially appointed to consider the question of lighting the classrooms, etc., by electricity. The details of the scheme were discussed in committee After discussion, a resolution was passed approving of a sub-committee's scheme of lighting the lecture-theatre, classrooms, and corridors. It was further resolved that a deputation should wait upon the Lighting Committee of the Dewsbury Corporation to see if they could arrange terms, etc. a report to be made to a meeting of the governors, to be held at an early date.

Eccles.—The work of putting down the electric light installation at the new Co-operative Stores is progressing rapidly. A main switchboard of the latest and most improved type, with lightning-arresters and measuring instruments will be placed in the engine-room, and electric bell circuit for signalling purposes established with the new premises. About 200 yards of main cable, carried overhead on suitable poles, will be required to convey the current to a main distribution-board on the ground floor. The dynamo has a capacity of about 250 16-c.p. incandescent lamps. The elevator in the new premises will also be worked by electricity from the same plant.

The City and Waterloo Railway.—This railway has made such advance that preparations are in progress for commencing the underground station at the City end of the line. From the river, the tunnels up Queen Victoria-street as far as Cannon street would have been commenced and would probably have been completed but for the requirements of the District Railway that the new line passing under their property should be excavated by the compressed-air system, so as to obviate any possible disturbance of the District Railway. They were empowered to do this by the Act of Parliament authorising the new enterprise. It is reckoned that this necessity has delayed the work by about three months.

New Companies.—The Telescriptor Syndicate, Limited, has been registered to enter into an agreement with B. Hoffmann for the acquisition of certain patents relating to improvements in telegraphic apparatus and typewriting machines, and to develop and turn to account the same. Registered office, 11, Victoria-street, S W. The International Improved Electric Company, Limited, has been formed to acquire the benefit of certain inventions for improved electric incandescent lamps and certain registered models, designs, and for a process for the manufacture of the same, and the letters patent, and to develop and turn to account the same. Registered office, 1, Arundel street, Strand.

Baker-street and Waterloo Railway.—The opposition that has been threatened to the Bill promoted by the Baker-street and Waterloo Electric Railway Company has been withdrawn. By this Bill, which has now passed unopposed through the Commons, powers are granted to the company to construct a short extension of their authorised line so as to connect with the London terminal station of the Manchester, Sheffield, and Lincolnshire Railway Company. The additional share and loan capital granted is £100,000. The Bill also authorises the construction of this railway in three separate sections, each section having a distinct capital. An extension of time is also granted until March, 1901, within which to construct this railway.

Coventry.—There is a deficiency of £1,112 on the year's working of the electric light undertaking ; but at a meeting of the City Council Mr. James remarked that the works were already nearly paying running expenses. The Council might, he thought, look upon the undertaking as being very satisfactory ; they could not expect in the first year to make provision for a sinking fund and interest on capital. They might look, however, to the department paying the whole of its expenses in a short time. The library is now lighted throughout by electricity. The specifications were drawn by Mr. Ram, the city electrician, and the work carried out by the Coventry Electrical Engineering Company, Limited, under the supervision of Mr. Eaves. The distribution-board system is used.

Kingston.—The Maldens and Coombe District Council are prepared to consider favourably the application of the Corporation to supply electricity in Coombe if terms satisfactory to the District Council can be arranged. Negotiations are still proceeding. At the meeting of the Town Council it was reported that a letter had been received asking what arrangements could be made for laying a main from the borough to Warren House, and it was agreed to suggest an interview on the matter. Replying to Councillor Brown, who again asked how much longer the services of Mr. Preece were to be retained as consulting engineer Councillor Collings repeated the answer which he gave at the last meeting, that as soon as the capital expenditure on which Mr. Preece was

Digitized by Google

engaged to advise had been completed his connection with the Corporation would terminate.

Slide Rules.—We have received a new compound slide rule, designed by Mr. C. N. Pickworth, Whit Sch., the author of the book called "The Slide Rule." This new rule is specially arranged for computing quickly the horse-power of gas and oil engines. It can also be used for steam-engine calculations, and for the inverse operation of determining the dimensions of an engine for a given power and speed. The other operations which can be carried out on the rule are the determination of piston speed; the speed ratios of pulleys, gear wheels, etc.; the circumferential speed of pulleys; the velocity of bells, ropes, etc; and the simple operation of finding the area of circles, etc. This rule, which can be obtained direct from the inventor, at Fallowfield, Manchester, at a net price of 5s., should find a ready sale.

Leeds.—At a meeting of the Parliamentary Committee the town clerk reported that the Mayor (the Right Hon. W. L. Jackson) had given notice in Parliament of a motion to suspend the standing order which prohibits a committee of Parliament giving power to a corporation working their own tramways. If this motion be carried, and the Committee of the House of Commons agree to the insertion in the Leeds Tramways Bill of a clause giving the Corporation the necessary power to work the tramways, the Bill will then have to go back to the House of Lords that the same subject may be dealt with there. The Corporation at present do not possess full powers for working the tramways of the city. All they are now authorised to do is to work the tramways until such time as some company or other shall lease them in accordance with the Corporation's terms and conditions.

New Companies and Electricity.—The following companies just registered take power to construct and work tram and rail roads, telegraph and telephone systems, electric works, etc., or to carry on the business of electrical engineers: the Goldfields of Venezuela, Limited, 53, Coleman street, E.C.; the Sanitary Supply Corporation, Limited, 52, Queen Victoria-street; Ransomes and Rapier, 32, Victoria-street, S.W.; Red Lion Chalk and Whiting Company, Limited, 16 Mark-lane, E.C.; Kamfersdam Mines, Limited, 18, Austinfriars, E.C.; South Zambesi Development Company, Limited, 3, Abchurch-lane; New Alburnia Gold Mining Company, Limited, Finsbury House, Blomfield-street, E.C.; Blocks 35, 37, and 39 Hampton Plains, Limited, 9, St. Mildred's-court, E.C.; Coolgardie Austral Gold Mining Proprietary, Limited, Winchester House, E.C.

Belfast.—At a meeting of the Electric Committee the engineer submitted his report upon the sites available for a generating station on a large scale, including two or three pieces of Corporation property, one of which, abutting on the river, is, we understand, likely to be selected, but the committee came to no definite resolution in the matter pending the granting of authority by the Council for the realisation of the committee's scheme. It is notified in the parliamentary papers issued on Saturday last that the petition presented by the Corporation against the Bill promoted by the Belfast Street Tramways Company has been withdrawn. The inference to be drawn from this is that the company has accepted the amendments submitted to them by the town clerk or so much of them as will meet the requirements of the Corporation. The Bill will now go forward as an unopposed measure.

Aberdeen.—At a meeting of the Electric Lighting Committee a report was submitted from Mr. Smith and Mr. Blackman, the electrical engineer, with reference to the proposed extension of the station in Cotton-street in order to provide additional electric light to meet the demand of customers. The proposed extension also provides for the erection of two new boilers. The total cost of the work is estimated at between £7,000 and £8 000. Negotiations are in progress between the Great North of Scotland Railway Company and the Town Council for the electric lighting of the Palace Hotel by current supplied from the Corporation mains. At present the railway company generate the current by means of their own plant. A committee of the Royal Horticultural Society of Aberdeen has been appointed to report on the electric lighting of the annual show, which will be held in the grounds of Gordon's College.

Southport.—Colonel A. G. Durnford has conducted an enquiry on behalf of the Local Government Board in response to an application by the Corporation for sanction to borrow £4,000 for electric lighting purposes. The Town Clerk (Mr. J. Davies Williams) said the Corporation had already expended £42,822 in the construction of an electricity works and in laying down the high-tension cables, transformers, and radiating low-tension mains, and in making the service connections. They now served by this means 150 private consumers with 11,500 lamps. The electric energy at Crowlands station was beyond this number of lamps, and the major portion of the £4,000 was to be expended in making that power practically available to further customers. They calculated that they would be able to serve another 100 customers without expending more than about £3,400, which would mean 7,500 lamps, or a total of 19,000. The enquiry then closed, and the inspector afterwards visited the electricity works at Crowlands.

Maidstone.—Once again Mr. Cox has got his own way, and unless his resolution is rescinded the harassed question of the provisional order will rest undisturbed for 12 months. But it would not be like the Corporation to put away such an interesting ninepin, and more than likely Mr. Cox's resolution will be rescinded before many weeks have passed, and the whole question will be reopened. At the last meeting of the Council Alderman Ellis moved that the terms offered by Mr. King for the purchase of the order should be accepted. Mr. Cox moved an amendment that the matter should be deferred for 12 months because he had been informed that there would be some startling results in the electrical world during that period. During the course of the discussion a long letter was read from Mr. Leavey, the present Mayor of Chatham, who is a ratepayer of Maidstone, urging the Council to lay down a suitable plant, and saying that he personally would be very glad to sign an agreement for the light at £120 per annum. In the end Mr. Cox's amendment was carried by 12 votes to 9.

Bristol.—At a meeting of the Sanitary Committee Mr. Yabbicom, the city engineer, presented his report on the application of the National Telephone Company, Limited, to lay wires underneath the public streets. Information was given as to how various corporations in the country had dealt with similar applications. He reported that Manchester appeared to have made good terms with the company, the latter agreeing to pay the Corporation 5s. per annum for each subscriber to the telephone exchange on a minimum of 3,000 subscribers, and 5s. for each subscriber over that number; an annual payment of 5s. or 10s. for each manhole, according to size, and 5s. per annum for each trunk wire placed in the tubes. To guard against these payments being charged to the subscribers of the company, the Corporation had inserted a clause which prohibited any increase of the annual subscriptions being made without the consent of the Corporation. It was agreed that the committee should recommend that the application should be granted, subject to charges of 3s. per subscriber, 20s for each manhole, and 5s. for each trunk wire.

Chelmsford.—The demand for the electric light by private consumers is increasing every week. The foundations for the new electric lighting station for the town have been laid, and plant will be put down in the station for the supply of 10,000 lamps. During the last quarter the number of private lamps in use has been increased by 350. The total number of such lights now installed is 3,800, and the company have orders on their books for at least 500 more. At the meeting of the Town Council the Lighting Committee reported that the town lighting contract with Messrs. Crompton and Co. having expired they had renewed the same for another five years, the terms—£22. 10s. annually for arc lamps and £2. 6s. 10d. for each incandescent lamp—being as previously. They further considered the company's offer to sell the proposed new station as a going concern, the entire plant and goodwill, together with the firm's provisional order. The price asked was £34,828, but the committee were unable to come to any conclusion until they had consulted some expert. The matter will now be considered by the whole Council.

Grimsby.—At a meeting of the Electric Lighting Committee Alderman Dobson said that the sub-committee recommended that some of the members of the committee should visit other towns where the electric light was being used with success, and then employ an expert and get his advice. Mr. Alward proposed that the recommendation of the committee to the Council be that they be empowered to proceed with the electric lighting scheme. He would suggest that they advertise for the best scheme for the lighting of Grimsby with the electric light, and that a visit be made to a few towns where the light was used with success. He would not recommend them to employ an expert. The provisional order expires in July next, and the Town Clerk said that if the committee would wait till the next session of Parliament, which would be in November, and then apply for an extension of the order, he did not think that there would be any danger of a private company stepping in before them. Mr. Alward then withdrew his resolution, there being no seconder. It was unanimously agreed to recommend to the Council that, as soon as the provisional order lapses, they apply for a renewal; and also that the sub-committee be empowered to visit other towns for information in the meantime.

London Lighting Extensions.—The London County Council have sanctioned notices of extensions from the following: Metropolitan Electric Supply Company, to lay mains in Boundary-road, St. John's Wood-park, Ordnance-road, Acacia-road, Henstridge villas and place, Norfolk-road, Woronzow road, Townshend road and cottages, Upper York-place, Eaton-terrace, St. John's Wood-terrace, Henry-street, Charles-street, John-street, Frederick-street, Barrow Hill-road, Avenue-road, Titchfield-road, Wells-road, Albert-road, Macclesfield Bridge, Outer Circle Regent's Park, Mortimer-road, Greville road and place, Belgrave road and gardens, Clifton hill, Carlton-hill, Blenheim-terrace, Abbey-road, Marlborough road, place, and hill, Loudoun-road, Finchley road and place, Langford place, Waverley-place, Queen's road and terrace; St. James and Pall Mall Electric Light Company, to lay mains in and across Jermyn-street; Charing Cross and Strand Electricity Supply Corporation, to lay mains on both sides of and across Buckingham-street and across Duke-street, and to construct two service boxes; County of London and Brush Provincial Electric Lighting Company, to lay low-tension mains in Spencer-street, Clerkenwell; Notting Hill Electric Lighting Company, to lay mains in Victoria-gardens, Ladbroke road, grove, and terrace, Holland-park-avenue, in a small portion of Holland-park, in Addison-road, in Palace-gardens-terrace, Brunswick-gardens, Berkeley-gardens, Silver-street, Sheffield-terrace, Campden House-road, and Gloucester-walk; House-to-House Electric Light Supply Company, to lay low-tension mains in Gilston-road and Fulham-road.

Dundee.—Last week about 50 members of the Institute of Engineers visited the telephone exchange, Panmure-street. They were first shown the new switchboard, the working of which was explained by Mr. Brown, the company's manager, and then the wire-testing apartment was visited, and a number of the members ascended to the roof and inspected the apparatus where

Digitized by Google

the 900 wires in connection with this exchange converge. The Gas Committee of the Town Council have just received the Board of Trade report with reference to the breakdown at the electric lighting station on January 21 last, owing to the explosion of a cast-iron steam-pipe. Mr. A. Watt, the Board of Trade engineer surveyor-in-chief, reported that the explosion was due to the expansion and contraction of the main steam-pipe, causing undue strain to be put on the cast-iron bend. There was also considerable vibration of the pipes, and the metal was of a spongy nature. After describing the machinery at the electric station, the engineer stated that the main steam-pipe was well supplied with steam-traps, and as the engine had been working for about four hours previous to the explosion it was not probable that there could be an accumulation of water in the pipes to cause the fracture. Mr. Peter Sampson, assistant secretary of the Marine Department of the Board of Trade, after considering the engineer's report, added that the arrangement of the steam-pipes appeared to have been such that any variations in the length of the main pipe due to its contraction or expansion would result in producing severe stresses at the part where the fracture occurred, and, as the metal appeared to have been of a spongy nature, it was not surprising that the explosion resulted.

Bray (Wicklow).—At a special meeting of the Township Commissioners, the town clerk read letters from Mrs. Stoney, Mrs. Quaine, and Captain Ffrench MacDermott objecting to the constructing of an electric tramway along the Esplanade road. A memorial signed by 200 residents in favour of the scheme was also read. A deputation from the promoters of the electric tramway scheme, consisting of Mr. Isaac Molloy, solicitor, Mr. Ryan, C.E., and Mr. Porte, C.E., was in attendance Mr. Molloy explained the scheme, and said the promoters were willing to give the Commissioners every satisfaction. Mr. Ryan stated it was proposed to lay a double line on the Esplanade road and a single line through the main street. It would be a 3ft. 6in. gauge. The Chairman asked Mr. Ryan if the Commissioners decided to make an underground system a *sine quâ non*, would the company be prepared to adopt it. Mr. Ryan said he thought not, as the underground system would be too expensive. The Chairman: Then if we don't agree to the overhead system the whole matter falls to the ground The deputation then withdrew. The Chairman said the question required serious consideration. The company had come to them on April 26 and told them they would require their decision before May 1. He wished to say that he was not prepared to give up to any company for all time rights over the streets of Bray. Therefore he considered the Board would be acting wisely if they did what had been done by the Corporation with reference to the proposed electric tramways for Dublin, and postpone the matter for some time—say, six or twelve months. Up to the present the scheme had not been sufficiently considered, and, as suggested by Mr. Clifton, they ought to get the opinion of the ratepayers on the question. Sir Rowland Fanning proposed that the further consideration of the scheme be postponed for six months. Mr. Condron seconded the motion, and it was adopted.

Lambeth.—At the last meeting of the Vestry there was a big batch of amendments on the agenda in connection with the provisional order question. The first of these required that the order should be put up to public tender, "and such tenders be reported on by a committee of two from each ward, appointed for the purpose." This was lost. The next amendment came from Mr. Iremonger, who proposed that a clause be inserted in the transfer securing due enforcement of Mr. Sax's chief conditions, with this important addition: "That the order be not disposed of, by sale or otherwise, without the consent of the Vestry being first obtained thereto." Mr. Woodward seconded the amendment, which, on a show of hands, was adopted. Mr. Rogers next submitted an amendment requiring the holder of the order to pay to the Vestry "all profits above 5 per cent., to form a fund with which the undertaking may be purchased by the Vestry in the interests of the ratepayers." This was seconded by Mr. Chalton Hubbard, but was on a division rejected by 50 to 20 votes. Mr. Bennetts moved that the report be referred back, with instructions to the committee to consider Mr. Offor's letter, which was read at the last meeting. On a division this amendment was rejected. Mr Stainsby proposed a further amendment, providing that the repurchase price should be at not more than the subscribed capital, "less such amount for depreciation of plant." This was seconded by Mr. Woollacott, but was negatived, as was another proposed by Mr. Corbin and seconded by Mr. Cooper. Mr. Price moved that the report be referred back, with instruction to the committee to enquire into certain allegations which had been made. Mr. Quick seconded, but this amendment was also rejected. The discussion was continued to the hour when, under the standing orders, the Vestry should adjourn. An endeavour was made to suspend the order and prolong the discussion, but this did not succeed. Thus the debate was further adjourned.

Worcester.—At the City Council meeting Mr. Millington pointed out that the estimates included for the first time the Electricity Committee account. The Council would see that they proposed to wipe off the deficiency of £1,950. On referring to the accounts of the Electricity Committee for 1895, they would find that the deficiency was stated to be £1,443 14s. 4d., but there was an item of £535 which would never occur again. The committee estimated that the amount of the deficiency next year would be reduced to £1,225. He had gone carefully through this estimate of the Electricity Committee, and he disagreed with one or two points During last year £1,092 was spent for coal, yet the committee said they would spend £1,000 this year. It was well known that a great part was used for experimental purposes and matters which would not occur again. During the first quarter of this year they had spent only £100 for coal. At the rate of £1,000 for the year they would have £250 a quarter. He did not see, therefore, how that £1,000 was going to be spent. But the committee said that they did not know what sort of a summer they would get. He thought the estimate excessive, however, on what would be required. The receipts on the sale of the current showed a great increase. There was also included £500 for motors at the waterworks, and the Water Committee had put in their original estimate—£600—in respect of that item. The estimate provided for interest on the sinking fund, and when they took a new concern like that, and the renewals, repairs, etc., into account, he thought the citizens would not be surprised to find that there was some deficiency which would have to be wiped off. They would agree he thought, that it should be wiped off, and enable the Electricity Committee to start with a clear balance-sheet for the next year. He instanced Bristol, where some £6,600 was wiped off in two years, Huddersfield £3,400, Blackpool £278, and Great Yarmouth £766. The course they proposed to adopt was therefore one adopted in other towns of more importance even than Worcester. The estimate was approved.

Islington.—At the meeting of the Vestry to-day (Friday) a report will be received from the Electric Lighting Committee stating that they have considered the Vestry reference of April 17 which directed them to consider and report and also to prepare an estimate of the cost of laying mains and providing the necessary plant for lighting by electricity such other parts of the parish as they may deem advisable. For some months past they have had the question of the advisability of extending the supply of electricity to other parts of the parish beyond the limits of the "compulsory" area under careful consideration, and with a view to arriving at a decision as to the desirability or otherwise of recommending such a course to the Vestry, they directed the electrical engineer to prepare and submit a report and estimate as to the probable cost of extensions in certain of the main thoroughfares outside such area. This report and estimate was, prior to the date of the Vestry reference, duly submitted to and under the consideration of the committee, and they recommend (*a*) that it be referred back to the committee to at once take steps for placing orders for the additional plant mentioned in the report of the electrical engineer, and for the necessary extension of the station to accommodate such plant at an estimated cost of £23,750, so that, if possible, such plant may be available for running during the ensuing winter; (*b*) that conduits and mains be at once laid in the Holloway-road, from the Nag's Head public-house to the Archway Tavern, at an estimated cost of £5,000; (*c*) that conduits and mains be at once laid in the Caledonian-road, at an estimated cost of £9,000, several applications for a supply of current having been received from occupiers in that road, including a requisition for current in the Wharfdale-road and neighbourhood equivalent to 3,000 8 c.p. lamps — referred by the Vestry on February 7, 1896; (*d*) that the consideration of the question of the suggested extensions along the Essex and Camden roads be deferred for the present. [Note.—We publish Mr. Gay's report *in extenso* in another part of the paper. Ed.]

Southampton.—At the meeting of the Town Council the Electric Lighting Committee reported that the town clerk submitted draft agreement with the Electric Lighting and Power Company, Limited, and having carefully considered the same, the committee have resolved that the deputy-chairman and town clerk be requested to see Mr. Manville, and to ascertain from him the terms upon which he would be willing to act as consulting engineer to the Corporation. Mr. Manville wrote stating that he should be happy to act as engineer for carrying out of the works included under his report for a fee of 5 per cent. on the actual contracts let for new works, such to be inclusive of all assistance and particulars required for any enquiries, the preparation of all plans and specifications, advising the committee on tenders received, supervising the carrying out of the works, and certifying payments to contractors—the fee being, in fact, an inclusive fee, covering all expenses except clerk of the works and quantity surveyor, who will be required for buildings only. The committee recommended the Corporation to appoint Mr. Manville as consulting electrical engineer upon the terms mentioned in his letter. They could not consent to a joint appointment in favour of Mr. Manville and Mr. Aldridge, but did not object to Mr. Manville making any personal arrangement with Mr. Aldridge. After correspondence with Messrs. Sharp, Harrison, Turner, and Turner, solicitors to the Southampton Electric Lighting and Power Company, Limited, on the subject of the debenture holders, the committee resolved that the purchase-money of £21,000 should be paid to the company in cash, but that in the event of the Corporation hereafter issuing stock at 2¾ per cent., the company should upon the date of such issue have the option of purchasing such stock to the extension of £5,000 only at par value. Alderman Bone proposed the adoption of the report, stating that Mr. Manville was an eminent electrical engineer, who had successfully carried out works at Portsmouth. When the Corporation agreed to purchase the works it was for £21,000, but there was a question as to compensation to the debenture-holders. It was found that they could not give them the option of taking the stock, and they recommended that the purchase-money should be increased by £100, which would get over the difficulty, and they would take possession almost immediately. Mr. Batchelor seconded the proposition, which was adopted, with the alteration referred to by Alderman Bone.

Kingstown.—Cars have been running between Haddington-road and Kingstown, at five minutes' intervals, testing the electric line to Kingstown and Dalkey, and the action of the cars, with the

Digitized by Google

most satisfactory results. The Great Southern and Western Company have now a great many drivers and conductors in their employment who have been trained in their respective duties, and who are now on salary. The line will, it is expected, be shortly opened for the accommodation of the public. The Board of Trade having granted the provisional order applied for by the Corporation. The Electric Lighting Committee reported, at the last meeting of the Commissioners, as follows: "The time having arrived when it becomes desirable to consider what system of electric lighting you will introduce into your township and whether you will exercise the powers conferred by the order or lease them to a company, your committee thought it necessary to secure the services of a consulting electrical engineer of eminence to advise on these matters. The importance of having such advice was enhanced by the fact that arrangements were being made for the reconstruction of the footpaths and the laying in connection with this work of a culvert or conduit for the electrical cable Your committee accordingly entered into communication with some well-known experts, and have arranged with Mr. Manville, of the firm of Kincaid, Waller, and Manville to visit the township and prepare a report on the subjects to which we have alluded. Mr. Manville's fee for this work will be 50 guineas, which will be included in his fees if he should be retained to draw plans and specifications for the lighting of the district and to superintend the execution of the works." The report was adopted. With regard to the tramways, Mr. T. W. Robinson, pursuant to notice, moved, "That in order to prevent any further delay in the opening of the tramway traffic in this township after the inspection by the Board of Trade, we hereby request the tramways company to forthwith enter into the necessary contract or arrangement under Section 2 of the Dublin Southern Districts Tramways Act, 1893, with respect to the user by the company, or the paving and keeping in repair of the part of the roadway within the township upon which the tramways are laid, or with respect to the payment by the company to the Commissioners, as roads authority, of an annual or other sum in relation to such user, paving and keeping in repair the said road." The motion was carried.

Battersea. — The result of the competition for the best method of dealing with a public supply of electricity in Battersea has now been announced. It will be remembered that in September of last year the Battersea Vestry invited competitive schemes for the lighting of the parish by electricity and for the utilisation of the dust destructor in connection therewith. With this object instructions to electrical engineers were prepared, and premiums of £50, £30, and £15 respectively were offered for the best three schemes submitted, it being stipulated that the schemes finally selected should become the absolute property of the Vestry, and the premium of the successful competitor, in the event of his scheme being carried out, to merge into and form part of the commission or remuneration for the supply of the necessary detailed plans, specification, etc., and for the general superintendence of the execution of the works. Each competitor was required to submit with his scheme a report as to the best method of utilising the waste heat from the destructor at the Vestry dust depôt in connection with the supply of electricity and to provide in his report for the following: (1) for lighting a small area—(*a*) the lighting of the main and side roads, and (*b*) the lighting of public and private property; (2) for extending the lighting (*a*) to all main roads and (*b*) to public and private property abutting thereon; (3) for extending the lighting (*a*) to all side roads and (*b*) to public and private property abutting thereon. Full sets of drawings and plans had to be submitted with each scheme and detailed estimates given of the capital outlay involved and of the cost of working, showing what advantage would be likely to accrue to the parish by its adoption and a comparison made with the present cost of lighting the streets by gas. The instructions were issued to 28 applicants, and in response 21 sets of schemes were submitted by December 12. These were opened by the committee on the following day. At this stage the Electric Lighting Committee pursuant to the authority of the Vestry, appointed Mr. Robert Hammond M.I.E.E., as the expert engineer to advise the committee and to report on each of the schemes submitted Mr. Hammond's report was a very lengthy document, and each scheme was carefully analysed on a uniform basis and the estimates dissected in a similar manner, the comments and criticisms of the expert following in the same order. By this arrangement an easy comparison was afforded while the comprehensive tabulated summary gave a succinct account of the whole of the schemes. Mr Hammond's report as to the relative merits of these schemes was fully considered by the committee, and in accordance with his recommendation the premiums last week were allotted by the Vestry as under: first (J), Mr. R. A. Dawbarn, M.I.E.E., on behalf of the Brush Electrical Engineering Company, Limited; second (M), Mr. W. Best, Woodlands-road, Ilford; third (F), Mr. J. Hardie McLean, 45, Broad-street, Oxford. These schemes were referred back to the committee, who have instructions to prepare a scheme for dealing with the electric lighting of the parish and to submit same to Vestry at an early date. The Vestry at their meeting also adopted the recommendations of the Electric Lighting Committee in respect to the lighting of the town hall by electricity, and have decided to put the work in hand at once. Mr. Hammond, who submitted a lengthy report upon the matter, has been appointed as the consulting engineer to carry out the work at a fee representing 5 per cent. upon the capital outlay. It is estimated that the cost of the scheme will be about £3 000. Application will be duly made to the London County Council for a loan of £3,000 for the purpose of defraying the cost. The generating works for the town hall lighting will be erected on the vacant land at the rear of the present buildings.

Electric Lighting Provisional Orders.—The following is a copy of memorandum stating the nature of the proposals contained in the provisional orders included in the Electric Lighting Provisional Orders (No. 1) Bill:—Cowes Electric Lighting Order, 1896: The undertakers under this order are the Cowes District Council. The area of supply is the urban district of Cowes. The order contains provisions that the District Council shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions. The order also contains provisions (1) for the approval by the Board of Trade of the system upon which energy is to be supplied, and the issue by them of regulations for securing the safety of the public, and for ensuring a proper and sufficient supply of energy; (2) for the execution of the necessary works and the breaking up of streets etc., and the alteration of pipes, etc, under streets; (3) for regulating the manner in which energy is to be charged for, and fixing the maximum price to be charged; (4) for the appointment, remuneration, and duties of electric inspectors, and the testing of electric lines and other works, and for holding enquiries by the Board of Trade as to the causes of accidents affecting the public safety; (5) for the supply, use, certifying, inspection, etc., of meters; (6) for the application of moneys received by the undertakers in respect of the undertaking; (7) for the transfer to any company or person of the powers, duties, and liabilities of the District Council under the order by means of a deed to be approved by the Board of Trade, upon such terms and subject to such exceptions and modifications (if any), and for such period as may be specified therein; (8) for the revocation of the order under certain circumstances. Folkestone Electric Lighting Order, 1896: The undertakers are the Corporation of Folkestone. The area of supply is the urban district of Folkestone. The order contains provisions similar to those referred to in the case of the previous order. Gloucester Corporation Electric Supply Order, 1896: The undertakers are the Corporation of Gloucester. The area of supply is the city of Gloucester. The order contains provisions similar to those referred to in the case of the previous orders. Huddersfield Electric Lighting Order, 1896: The undertakers are the Corporation of Huddersfield. The order is to be read in conjunction with the Huddersfield Electric Lighting Order, 1890, and extends the area of supply authorised by that order. King's Lynn Electric Lighting Order, 1896: The undertakers are the Corporation of King's Lynn. The area of supply is the borough of King's Lynn. The order contains provisions similar to those referred to in the case of the Cowes Electric Lighting Order, 1896, above mentioned. Manchester Electric Lighting Order, 1896: The undertakers are the Corporation of Manchester. The order is to be read in conjunction with the Manchester Electric Lighting Order, 1890, and extends the area of supply authorised by that order. City of Wells Corporation Electric Lighting Order, 1896: The undertakers are the Corporation of Wells The area of supply is the city of Wells. The order contains provisions similar to those referred to in the case of the Cowes Electric Lighting Order, 1896, above mentioned. The following is a copy of memorandum stating the nature of the proposals contained in the provisional orders included in the Electric Lighting Provisional Orders (No. 2) Bill:—Colwyn Bay and Colwyn Electric Lighting Order, 1896: The undertakers under this order are the Urban District Council of Colwyn Bay and Colwyn The area of supply is the urban district of Colwyn Bay and Colwyn. The order contains provisions that the District Council shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions. The order also contains provisions similar to those mentioned in No. 1 Bill Devonport Corporation Electric Lighting Order, 1896: The undertakers are the Corporation of Devonport. The area of supply is the county borough of Devonport The order contains provisions similar to those referred to in the case of the previous order. Godalming Electric Lighting Order, 1896: The undertakers are the Corporation of Godalming. The area of supply is the municipal borough of Godalming. The order contains provisions similar to those referred to in the case of the previous orders. Kettering Electric Lighting Order, 1896: The undertakers are the Urban District Council of Kettering. The area of supply is the urban district of Kettering. The order contains provisions similar to those referred to in the case of the previous orders. Kingstown Township Electric Lighting Order, 1896: The undertakers are the Commissioners of the township of Kingstown The area of supply is the township of Kingstown. The order contains provisions similar to those referred to in the case of the previous orders. Middleton Electric Lighting Order, 1896: The undertakers are the Corporation of Middleton. The area of supply is the borough of Middleton. The order contains provisions similar to those referred to in the case of the previous orders.

PROVISIONAL PATENTS, 1896.

APRIL 20.

8262. Apparatus for fastening and tightening wires for electric streams to insulators by means of a lever. Max Commichau, Zwickau, Saxony.

8269. An improved system of running and insulating concentric electrical conductors and appliances in connection therewith George Wilkinson, 73, St. Stephen's-road, Upton Park, London.

Digitized by Google

8271. Improvements in or relating to electric traction. Wilfred Swanwick Boult, 111, Hatton-garden, London.

8308. Improvements in or connected with electrical resistances. Valere Alfred Fynn, 47, Lincoln's-inn-fields, London.

APRIL 21.

8316. Improvements in electric switches. Elmer Howard Wright, James Jean Heckman, Albert Henry Graves Charles Calvin Carnahan, and William Henry Carnahan 11, Southampton-buildings, Chancery-lane, London. (Complete specification)

8320. Support or bearing for electrical accumulators or other apparatus; having for its object the minimising of vibration. Guiseppe Fabbro, Morton House Trott street, Battersea, London.

8323. A new or improved process of electrically treating fabrics for waterproofing and other purposes. Charles Melbourne White, 27, Southampton-buildings Chancery lane, London. (The Electro Waterproofing and Dye-Fixing Company, United States) (Complete specification.)

8336. Improvements in and connected with electric tramways or railways. Andrew George Adamson, 154, St. Vincent-street, Glasgow.

8338 Improvements in the mode of connecting the car with the overhead wire in tramways worked by electricity. William Henry Kenway, 66, Corporation-street, Birmingham.

8380. Improvements in printing telegraph instruments. Benjamin Frederick Merritt and John Marston Joy, 45, Southampton-buildings, Chancery-lane, London (Complete specification.)

8382. Improvements in automatic circuit breakers for use in electric tramcars or other electrically-propelled vehicles. James Devonshire, 70, Chancery-lane, London. (William B. Potter United States) (Complete specification.)

8397. Improvements in electrical cut-outs. Henry Edmunds, 47, Lincoln's-inn-fields, London.

8398. Improvements in or connected with electrical resistances. Henry Edmunds, 47, Lincoln's-inn fields, London.

8399. Improvements in apparatus for completing, interrupting, and controlling electrical circuits. Henry Edmunds, 47, Lincoln's-inn-fields, London.

8410. Improvements in the electro-deposition of metals, particularly applicable to the deposition on wires. John Cameron Graham, 18, Southampton-buildings, Chancery-lane, London.

APRIL 22

8428. A new or improved electric switch. John Benjamin Verity, Plume Works, Aston. Birmingham.

8458 Improvements in electrical recording instruments. William Turvey, 4, Aubrey-walk, Campden Hill, London.

8483. An improvement in joints for electrical cables. Siemens Bros. and Co , Limited, and Wilhelm Dieselhorst, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

8507. Improvements in chandeliers, gasoliers, electroliers, and other hanging lamps. James Hinks and Son Limited, and Francis Robert Baker, 7, Staple-inn, London.

8512. Improvements in or connected with drain pipes, water or electric conduits, and the like. George William Dolman, 7, Southampton-buildings, Chancery-lane, London.

8514. Improvements in electric glow lamps. Illius Augustus Timmis, 2, Great George-street, Westminster.

APRIL 23.

8541. Improvements in electric lamps for miners and in the method of lighting said electric lamps. William Woodhead, Commercial-street, Halifax.

8569. Improvements in apparatus for making electrical contact by passage of a railway train. Edward Tyre, 28, Southampton-buildings Chancery lane, London.

APRIL 24.

8630. Improvements in magnetic motors James Chandler, 10, St. George's-crescent, Liverpool

8647. Improvements in induction electrical machines. Frederick Tudsbury, 15, St. James-row, Sheffield.

8659 Improvements in paste-carrying plates for electric accumulators. Friedrich Wilhelm Schneider, 18, Buckingham-street, Strand, London. (Complete specification.)

8660. Improvements in the construction of cells for electric accumulators. Friedrich Wilhelm Schneider, 18, Buckingham-street, Strand, London. (Complete specification.)

8666. Improvements in and connected with battery electrodes. The Battery and Motor Company, Limited, and Harry Theodore Barnett, 433, Strand, London.

8682. Improvements in hand grenades and in electrical firing apparatus applicable for firing the same. Charles Ambrose McEvoy, 24, Southampton-buildings, Chancery-lane, London.

8684. Improvements relating to telephones. Francis Lauder Muirhead, 124, Chancery-lane, London,

8695. Improvements in electrodes for accumulators. Wilhelm Majert, 115, Cannon-street, London. (Complete specification.)

APRIL 25.

8743. Improvements in speaking-tube, telephone, and the like receivers. Hahnemann Adolphus Cutmore, 7, Quality-court, Chancery-lane, London.

NOTES.

The Mechanical Engineers.—At the anniversary dinner last week of the Institution of Mechanical Engineers, held at the Freemasons' Tavern, the principal guest was Mr. Bayard, the American Ambassador.

Vienna and Berlin Telephone.—According to the *Zeitschrift für Elektrotechnik*, telephonic communication has been in operation between Berlin and Vienna since April 1. The cost of a single conversation is about 3s.

Northern Electrical Engineers. — Mr. John Hesketh is to read a paper on the use and economies of rectifiers in arc lighting before the Northern Society of Electrical Engineers at Manchester on May 11.

Bacteria.— According to some experiments of Mr. Lortet communicated to the Paris Académie des Sciences, active bacilli are sensitive to the action of an alternating current, and arrange themselves parallel to the direction of it.

Sir John Pender Gold Medal.—This medal, of the value of £5. 5s., which is presented to the best student of electrical engineering at the Glasgow and West of Scotland Technical College, who at the same time obtains the college diploma, has just been awarded to Mr. Alexander H. Waddell, from Uddingston.

Petroleum Lamps.—The dangers of petroleum lamps have been enforced over and over again, but nobody troubles about "safety rules" for using them. To the list of deaths caused by these lamps must now be added that of Prof. Geffcken, who was suffocated in his sleep at Munich last week by the explosion of one left alight in his room.

Winkelmann's Solution.—As the basis of a solution for impregnating wood used in electric installations in order to render it uninflammable, the *Elektrotechnischer Anzeiger* gives the following (Winkelmann's process): 33 parts (by weight) of manganese chloride, 25 of ammonium chloride in 1,000 of water, 20 of ortho-phosphoric acid, 12 of magnesium carbonate, and 10 of boric acid.

Zirconium Carbides.—The researches of Mr. Henri Moissan and others with the electric furnace have shown that under the influence of the electric arc zirconium forms a carbide of the formula ZrC_2. It now appears that at lower temperatures another carbide of the formula ZrC is produced. This does not decompose water, but is attacked by acids and by oxidisers—in the latter case very vigorously.

Obituary.—There died last week in London, from heart disease, at the age of 75, Peter John Margary, one of the assistants of I. K. Brunel in the construction of the Bristol and Exeter Railway, and subsequently of the South Devon line, of which and its branches he became chief engineer on the death of Brunel. On the amalgamation with the Great Western Company, Mr. Margary was appointed resident engineer of the western division of the system, a position he retained until 1891.

The Earl's Court Show.—The electric illuminations were always a striking feature at the Indian Exhibition, and it will be remembered that the machinery of the generating station there has been the subject of an article in this paper. It may now be noted that one of the additions to the show for the present year is to be a Belvedere tower, 250ft. high, with a "4,000,000-c.p. lamp" at the top of it. That ought to be a noticeable feature in the neighbourhood at night-time.

Institution of Electrical Engineers.—There is to be a students' visit to the Robertson incandescent lamp factory at Brook Green, Hammersmith, on Friday, May 15, at 5 p.m. The party is limited to 20, and those desiring to be included should communicate with Mr. Allingham, at Eldon House, Lyndhurst-road, Hampstead. It should be added that "an assurance is required by the General Electric Company from each student joining the party that he is not commercially interested (directly or indirectly) in incandescent lamp manufacture."

Exhibitions.—May 1 was the day for the opening of the Swiss National Exhibition at Geneva, and also of the Berlin Industrial Exhibition, which occupies an area to the east of the Kaiserstadt, on the Spree, the grounds being nearly one-third larger than those occupied by the last Paris exhibition, or by any other exhibition ever held in Europe. The Hungarian Exhibition was also opened on the same day at Budapest. In Vienna, which likes to look down upon the Hungarian capital, having no exhibition to open, they had a labour riot instead. On the whole, this time Budapest seems to have had the best of it.

Royal Institution.—The annual meeting of the members of the Royal Institution of Great Britain was held last week, Sir James Crichton-Browne presiding. The annual report of the committee of visitors for the year 1895, which showed the continued prosperity and efficient management of the institution, was read and adopted. The real and funded property now amounts to above £100,000, entirely derived from the contributions and donations of the members and of others appreciating the value of the work of the institution. Seventy-two new members were elected in 1895. The Duke of Northumberland was elected as president, Sir James Crichton-Browne, F.R.S., as treasurer, and Sir Frederick Bramwell, F.R.S., as secretary for the ensuing year.

Trinidad Rock.—It will be remembered that when the British flag was hoisted on the island of Trinidad in the South Atlantic, in order that it might be secured for the purposes of a cable to the Argentine, the Brazilian Government, to whom the island did not belong, and who had no use for it, protested vigorously. Among our multifarious foreign difficulties this particular one has been nearly forgotten; but the Brazilians are keeping it alive and in case purely "patriotic" motives might not be sufficient, they have started a report in Rio Janeiro that there are rich mines of the precious metals in the island. Considering the formation of the island, this is excessively unlikely. It is true that Mr. Knight went there years ago to find some silver—not with success. But then he thought he knew that someone had put the silver there first.

Waterloo and City Railway.—This company having successfully met and dealt with the engineering and natural difficulties incidental to such an enterprise, appears now to be likely to have to face a serious one of artificial manufacture. At a special meeting of the executive of the Engine and Crane Drivers' Union held at the chief offices, Barking-road, it has been decided to call out their members to enforce an advance of ½d. per hour and a code of working rules similar to those demanded by the members of the various federated building trades unions who are at present on strike. Between 300 and 400 engine and crane drivers engaged in the building industry in the Metropolis will be affected by this decision. It is stated in the *Daily Mail* that, as a result of this, the men working the engines and cranes for the Waterloo Railway have come out and that the pumping operations have ceased, and the entire foundations of the works are in danger of becoming flooded.

Proposed Spanish-American Cable.—A good deal of space continues to be devoted by *El Telegrafista Español*

Digitized by Google

to the proposed Transatlantic cable from Spain to Cuba. No further details are at present obtainable of the conditions under which it is stated this cable will be laid by a "foreign firm" (a well known one); but Mr. Angel Guerra hopes that it will be stipulated that the cable shall be worked by members of the Spanish telegraphic service, deprecates the results of precipitate action, and complains of the habitual want of foresight of the Spanish authorities. Too rapid conduct of business is not usually a Spanish fault, and the position of the Spanish Government is just now a very difficult one. Admittedly it cannot lay the cable itself, and if it can get a cable laid for it on anything like the terms set out in Mr. Guerra's former articles, it will on his own showing be doing an exceedingly good piece of business, while the Spanish telegraph service will be no worse off than before.

"Knowledge."—The May number of *Knowledge* has been forwarded to us with a request for review. It is a magazine with a record of which no one need be ashamed. If at one time it was perhaps too exclusively astronomical and at another too photographic, it has always maintained a high standard for the work that has appeared in it, which is more than can be said for a great deal of what passes under the name of "popular science." The present number is a fair example of the wide range covered. Three articles relate to biology or natural history and two are astronomical. Mr. Hill writes about early English coins, and Mr. Vaughan Cornish endeavours to elucidate some of the phenomena of wave motion—an exceedingly difficult subject for popular treatment; but the article of the number is Mr. T. G. Pinches's article on three fragments of a Babylonian tablet, in which he has discovered some long-wanted information with reference to Chedorlaomer and the strength and importance of Elam about 4,000 years ago.

Cables to Spain.—Mr. Henniker Heaton wants the telegraphic rates to Spain reduced. Last Friday in the House of Commons he asked the Secretary to the Treasury, as representing the Postmaster-General, whether, seeing that the telegraph rate from England to Spain is 4d. per word, and only 2d. per word from England to Germany, he would state when the concession of the cable company to Spain will expire; and if any measures would then be taken for the acquisition of the cable by the British Government, with a view to a reduction of the rate. Mr. Hanbury said two companies had cables between England and Spain, the Direct Spanish and the Eastern. The license to land the cable of the former company on the shores of this country would expire in 1903, and the license for the cable of the latter in 1904. It was too soon to say what the action of her Majesty's Government would be at the time in question. Considering the way in which cables are being laid, or, at any rate talked about, it would certainly be rash to say what would be the proper thing to do in eight years' time.

Field Magnets.—Induction coils are wound in a number of sections, which effectively prevent too close proximity of those portions of the winding between which there is a high difference of potential. The New York *Electrical World* says "the frequency with which the insulation of 500-volt shunt field coils is punctured by abruptly breaking the field circuit suggests that the same method of isolated sections be applied to field windings." Our American contemporary adds that the sectional construction would greatly promote ease of repair. With sectional construction a fault could be located in its particular section and thus avoid the necessity of unwinding the whole magnet. Again, "if the magnet winding were designed to be highly efficient and used but little current, the breaking down of one of its sections would not disable it. By simply short-circuiting the defective section, or, in case of a ground, removing it from the field circuit altogether, the magnet winding would generate exactly the same magnetising flux as before, with the exception that it would run a little hotter and use a little more current."

Three-Phase Arcs.—In a paper read before the American Institute of Electrical Engineers, Mr. W. L. Puffer has given the results of observations on the alternating-current arc, which he has been studying mainly by stroboscopic methods. So far as the simple alternating arc is concerned, Mr. Puffer has not brought out much that is new, but he has carried on his investigations to arcs produced by three-phase currents. He states that the three-phase arc is less noisy than the single-phase, and its light is steadier and has less variation in its total intensity, owing to the fact that the current never stops, and there is always a positive carbon. Three-cored carbons, placed parallel side by side, with slight magnetising coils to keep the arc at the ends of the carbon, will give a very satisfactory light in the direction away from the tips, and may be used when it is desirable to throw the light all in one direction. Four carbons at 90deg. apart, each with a suitable resistance in series with it, and connected to quarter-phase tap wires on a Gramme ring or other generator giving quarter-phase circuits will also produce a rotary field arc of great beauty and interest.

The American Pacific Cable.—A telegram from Washington, dated May 6, states that the United States Senate Committee on Foreign Relations have agreed to the Bill for the construction of a United States-Hawaii-Japan cable, and authorise the Postmaster-General to contract with any company to lay the cable, the subsidy not to exceed 160,000dol. yearly. The report of Mr. Frye to the Senate on the subject declared that the Hawaiian cable was demanded by the exigencies of commerce. It referred to the importance of Pearl Harbour and the necessity for telegraphic communication with Hawaii to direct the operations of the Pacific fleet in case of war. The Americans seem to derive a fearful joy from talking about what they would do in the event of a war with Great Britain. This has to come into the report somehow, so it is mentioned that in the event of the severance of peaceful relations with Great Britain communications by way of Nova Scotia would be immediately cut off, and the United States would be dependent upon the cable from Brazil to Portugal. The cost of the new cable is estimated at 3,400,000dol., and the maintenance at 586,000dol. yearly for the first five years.

A Wonderful Lamp.—Mr. Rudolf Schnabel, of Dresden, has written to the *Elektrotechnischer Anzeiger* (May 3) to say that he has discovered a new material which will be of great service in electric lighting work. No details are given as to the constitution of the material, but it appears to be a powder. The weight used is a quarter of a gramme, and the price of it 6s. a kilogramme. The lamp takes the form of a marble slab, with a groove and a shallow cavity to receive the powder. Carbon leads are used. It is stated that 16 watts (four amperes at four volts) give a power of 20 candles; that the light is whiter than that of an incandescent lamp, but contains more yellow than violet rays. The temperature of the incandescing material is such that iridium wire at once melts and is vaporised within three or four minutes. Editorially, the *Elektrotechnischer Anzeiger* points out that the new lamp claims an efficiency of ·8 watt per candle as compared with 2½ to 3 watts for an ordinary incandescent lamp (in England we use lamps of lower efficiency than this), and makes the obvious remark that a low-potential lamp

Digitized by Google

of this kind could not be used in parallel on any existing systems. It is added that the discovery of Mr. Schnabel will be one of far-reaching importance if the particulars given above can be maintained; the life of the lamp is reasonably long, and the cost of installation not too great. The result of trials of the lamp is still to be awaited.

Chronographs in Gun Ballistics.—Last Friday, at the Royal Institution, Colonel H. Watkin, C.B., in his "discourse" on "Chronographs and their Application to Gun Ballistics," remarked that in designing chronographs for gun work the object in view was to discover the resistance offered by the air to projectiles, and to measure the rate of the passage of a shot up the bore of a gun in order to determine the pressure exerted by the powder, and therefore the shape the gun should assume in order to resist that pressure. Colonel Watkin explained and showed in action his improved apparatus employing a revolving drum driven very rapidly by an electromotor, and he explained how the speed was determined accurately by comparison with the time taken by a weight to drop through a known distance, and also described a method of smoking the drum which ensured minute records. If it were just rubbed over with benzole in which a small piece of paraffin wax was dissolved, the records left by the spark were large and easily found, but at the same time had a minute centre which could be read with great nicety. Explanations were given of the modes of testing the accuracy of the records obtained by means of the induction coil and of measuring the retardation which, with the drum of the instrument as shown revolving at a circumferential speed of 65 miles an hour, was only equivalent to ·015in. Artillerists had not yet found a satisfactory way of ascertaining the velocity of shot just in front of the muzzle when for a certain time it was still gaining speed, but Colonel Watkin proposes to resort to photographic methods for this purpose.

Motorcart Legislation.—The Walsall Chamber of Commerce evidently do not like motorcarts. They have been discussing the subject and want a few provisions introduced into any Bill legalising their use. In the first place, all self-propelled vehicles should carry a red and a white light. They should be limited to eight miles an hour in towns, and should carry a "conspicuously-placed" speed indicator so that there should be no doubt about the speed they are going at. Besides the lamps, they should carry bells which must ring the whole time the vehicle is in motion. Also they must stop whenever anyone with a horse signals them to do so. Probably a motorcart with the above-mentioned bell-ringing arrangement would get signalled to stop a good deal in the course of a journey down the Strand. Lastly, when used for hire there must be a "certificated" person in charge. This is in the interest of the passengers. The harmless pedestrian may, it appears, be run over by an unlicensed person if the latter is riding for pleasure only. Copies of these preposterous regulations have been sent for approval to the six Saddlers' Associations, the principal Chambers of Commerce, all the M.P.'s on the Executive Council of Associated Chambers of Commerce, the Worshipful Company of Saddlers, Worshipful Company of Farriers, Worshipful Company of Loriners, Worshipful Company of Curriers, Worshipful Company of Leather Sellers, Worshipful Company of Skinners, Royal College of Veterinary Surgeons; and each association has been asked to obtain the support of Members of the House when the amendments are moved. Some of these bodies seem to be hardly the best qualified or disinterested judges as to the safety of motorcarts, but probably that is why the Walsall Chamber chose them. Unkind persons might suggest that what the Walsall people are afraid of is not so much being run down by motorcarts as that, if the latter come into use, there may not be so many horses in the streets, and therefore the harness and leather trades will suffer. Their fears are likely to be groundless in this respect for many years to come.

Methods of Teaching.—In last week's issue of *Nature*, in the course of a review, there occurs a remarkable plea in favour of teaching electricity on the historical method. Apparently, we are to begin with Gilbert and Cavendish, or even earlier. If life were long enough it might be possible for the student to acquire his knowledge in this manner, passing gradually from one incomplete conception to another, and taking up the properties of more or less impossible "fluids" only to discard them. But what would be the good of it all? Useful as the historical method has been in philosophy and politics in tracing the origin of laws, customs, and ideas, and explaining how it has come to pass that people have been ready to die for the sake of demonstrable falsehoods, in the teaching of practical physics it seems to have no place. It is not easy to judge how much a general knowledge of mathematics is retarded by the fact that under literary and historical influences we are compelled to obtain our introduction to geometry by means of a text-book written about 2,100 years ago before arithmetic was rationalised or algebra thought of. Experience shows that the way in which a principle is discovered is rarely or never the way in which it can be most clearly and succinctly stated. The first thing for the student to do is to understand. If he has time and inclination, he can go into history afterwards. Even now, most elementary electrical teaching begins with the frictional machine and its equivalents instead of with the dynamo and transformer. When some of our highest authorities are considering how in the interests of education this state of things can best be altered, it is curious to meet with a proposition to take electrical teaching further away from, rather than to bring it nearer, existing knowledge and practical needs.

Tramway Law.—In the United States each State makes and unmakes its own laws much as it pleases without regard to the rest of the country. This may have its inconveniences, but, if there are any, it is the Americans who feel them, while we on this side of the water can, if we are wise, profit by their experience. One result of the work of the Legislature of the State of New Jersey, which has just risen, is the addition to the statutes of five laws of importance relating to electric railways. These were drawn by the Association of Traction Companies of New Jersey, which includes every horse and electric railway in the State. Senate Bill No. 115 is intended to prevent the institution of suits for damages against any railway company by lawyers who offer to hunt up the evidence for the injured, and who take most of the money for their services. It appears that in America a number of law firms make a business of sending out detectives immediately after an accident to hunt up evidence, and that they get most of the money recovered and the injured person very little. Senate Bill No. 116 bears also on the subject of damage suits. It allows the trolley companies, when a suit for personal damages is brought, to apply to the court to have a physician appointed to make an examination of the injured person, so that the physician can qualify as an expert. Senate Bill No. 134 limits the time within which action for personal injury can be brought to two years from the time the person is injured. Senate Bill No. 181 gives the governing body of any municipality the power to grant a franchise by two ordinances instead of one—one granting the right of way, and the other containing a description of the places for poles, etc. Should

Digitized by Google

any change be desired in the latter, the one ordinance can be amended without affecting the franchise of the road. Senate Bill No. 182 validates all franchises of trolley roads now established which might be invalidated by mere technical defects in the placing of poles or some similar cause. The Bill prohibiting trolley roads from carrying freight passed both Houses and is in the hands of the Governor. It was amended in the Senate so as not to apply to roads already carrying freight.

Liability for Crossed Wires.—Canadian law is not necessarily the same as English law, particularly in the province of Quebec, but the following case given by the Montreal *Star* may be of interest on this side of the water. It will be noticed that the inevitable fuse which does not act when it is wanted comes into the case and plays an important part. It should be added that the decision will be appealed from. Our contemporary says: "Hon. Justice White has rendered an important judgment at Sherbrooke, Que., in the case of the Richmond County Electric Light Company *v.* the Sherbrooke Telephone Association, condemning the defendants to pay plaintiffs 218·63dol., on account of the wrecking of a dynamo at the plaintiffs' station, through the act of the defendants in allowing one of their wires to cross the plaintiffs' and produce a short-circuit. There was a fuse placed on the plaintiffs' line, which was designed for the protection of the dynamos in the station; but this did not blow or melt at the time of the cross. The defendants contended that the fuse was an absolute protection, and that if there had been a short-circuit outside it surely would have blown; consequently the wrecking of the machine was caused, not by a short-circuit from outside, but by the defective construction and state of repair of the machine. Judge White ruled against this pretension, discounting the evidence of the experts, who, he said, were always interested in favour of the parties summoning them. More reliance could be placed upon the opinions of the electrical engineers, members of the American Electrical Institute, who had recently met to discuss this very subject, at Niagara, where the distinguished electrician, Walter E. Harrington, closed his paper with these words: 'The natural conclusion arising from the knowledge of the above data is that fuse metals are under no circumstances to be considered in the light or nature of a protection.' Out of the nine experts who joined in the discussion, not one of them expressed an opinion that the fuse is an inevitable protection. One of them said it was 'in most cases'; another said it was 'in some cases'; while Mr. Harrington was of opinion that in no case could it be absolutely relied upon as a protection. Judge White held the evidence adduced showed that the injury to the dynamo could have been so caused although the fuse did not blow; that the damage resulted from the contact which it was established had taken place; and that the defendants were to blame for that contact."

Very Long-Distance Transmission.—Paragraphs have appeared in the American Press to the effect that at the opening of the New York Electrical Exposition this week power would be conveyed to the Exposition from the dynamos of the Niagara Power Company at Niagara Falls. There were the usual allusions to Mr. Tesla, who appears to serve as a second string to the American journalist's bow when Mr. Edison has been done with, and so far as the general public were concerned there was nothing to show that there was not to be a transmission of power on a practical scale. As the distance from Niagara to New York is something over 450 miles, as things stand at present anything of the sort is out of the question. How long it may remain so is of course a different matter. The New York *Electrical Engineer*, however, tells us what is really intended to be done. It was desired to mark the completion of the electric power plant at Niagara and the contract made by the city of Buffalo for its delivery within the city limits by June, 1897, in some way at the National Electrical Exposition in May. With this end in view, the management obtained a model made to scale by Mr. G. R. Allen, of Philadelphia, for the Hon. Peter A. Porter, of Niagara Falls. The model was constructed under the direction of Dr. Coleman Sellers, of the Niagara River, and shows the power-house, the town, and the long discharge tunnel, with the turbines in actual play operated by water from the canal and driving the generators. The model is 12ft. by 4ft., and will be given a place of honour on the main floor. It then occurred that, as little power was required to drive the turbines, it might be comparatively easy to switch on a modicum of current from the Falls plant and actually run the model with it, not as an ideal exemplification of what might be done, but more as a pretty *tour de force*. To get the circuit was the problem, but General Eckert, president of the Western Union Telegraph Company, authorised Mr. A. S. Brown, the electrical engineer of the company, to place two of their ordinary copper commercial wires at disposal, for use every evening, say for an hour or so, when the weather conditions are normal. Mr. L. B. Stillwell, of the Westinghouse Company, was asked to co-operate with Mr. Brown in working out the details, it being the intention to use the Tesla two-phase system and apparatus. A further suggestion was to hang some American Bell long-distance telephones over the exhibit and thus give the roar of Niagara as well as the model, and steps are now being taken to realise this.

The Metric System.—It is now no longer a secret that the articles in the *Times* in opposition to the adoption of the metric system were from the pen of no less a person than Mr. Herbert Spencer. They were doubtless somewhat of a surprise to many admirers of Mr. Spencer, who believed that the whole of his time was occupied with other matters. His last words on the subject are: "Arguments and expressions of opinion may be continued without end. Against those of Lord Kelvin and Dr. Stoney I will simply set some facts already stated, joined with one other: (1) Always mankind had the decimal system at their finger ends, and used it for counting. In the course of civilisation they departed from it in their systems of weights, measures, and values, gradually adopting instead sets of easy aliquot divisions, especially duodecimal divisions. (2) For half a century and after the metric system had been legally established the French did not discover its convenience. The alleged discovery of its convenience went along with the discovery that they would be punished if they did not use it. (3) In the United States, where the decimal division of money is used, it has been departed from in the centre of most active business, the Stock Exchange, and a system of easy aliquot divisions employed in its place. (4) The additional fact not yet named is sufficiently striking. The ancient wise men of the East and the modern working-men of the West have agreed upon the importance of great divisibility in numerical groups. The Chaldean priests, to whom we owe so much, doubtless swayed in part by their astronomical arrangements, adopted the sexagesimal system of numeration, which at the same time facilitates in a special manner the division into aliquot parts. For 60 may be divided by 10 different numbers—2, 3, 4, 5, 6, 10, 12, 15, 20, 30. From this significant fact turn now to the fact presented in our ordinary foot-rule. Each of its 12 inches is halved and rehalved, giving halves, quarters, and eighths. And then if we consider the subdivided

Digitized by Google

foot as a whole, it gives us 10 sets of aliquot parts. Beyond its twelfths the divisions yield $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{3}$, $\frac{1}{6}$, $\frac{1}{8}$ ($1\frac{1}{2}$in.), $\frac{1}{16}$ ($\frac{3}{4}$in.), $\frac{1}{24}$ ($\frac{1}{2}$in.), $\frac{1}{32}$ ($\frac{3}{8}$in.), and $\frac{1}{48}$ ($\frac{1}{4}$in.). And this ordinary mode of dividing the foot-rule results from the experience of centuries; for builders, carpenters, and mechanics, always buying foot-rules which best serve their needs, have gradually established the most useful set of divisions. Yet now, though the early men of science and the modern men of practice are at one in recognising the importance of great divisibility, it is proposed to establish a form of measure characterised by relative indivisibility."

Motorcarts.—On Friday last the Motorcar Club gave a private view of several of the self-propelling carriages and cycles which will form part of the forthcoming exhibition at the Imperial Institute. The majority of the machines were driven by oil-motors of various types, but there was an electrical carriage designed by the Universal Electrical Carriage Syndicate and a Serpollet steam-carriage. The latter, though heavy and clumsy in appearance, made as little noise as any of the machines, and gave off no smoke or smell. The show was attended by many well-known people, including Lord Harris, who, as under-secretary for the Board of Trade, has charge in the House of Lords of the Bill removing existing restrictions on the use of self-propelled vehicles on the public roads. The inaugural dinner of the club took place on the same occasion, the chairman of the club, Mr. H. J. Lawson, presiding. Among the speakers was the Comte de Dion, president of the Automobile Club of France. The International Horseless Carriage and Roads Locomotion Exhibition at the Crystal Palace was opened last Saturday by the Lord Mayor. Prior to the opening function the palace directors entertained a large party to luncheon in the grand summer dining-room, Mr. G. T. Rait presiding. In addition to the City functionaries, there were present, among others, Sir Redvers Buller, Lord Harris, Sir David Salomons, Lord Provost Dewar, Sir A. Harris, Mr. Wyndham Portal, Sir E. M. Shaw, Major Flood Page, and Prof. D. E. Hughes. As for the show of motorcarts, the Universal Electric Carriage Syndicate exhibit an electrically-propelled phaeton to carry four persons. This carriage has already run over 100 miles in London. The same exhibitors show an electrically-propelled landau to carry four persons inside and two out, and also an electric van in course of construction for a London firm of contractors. The Electric Motive Power Company have on view an omnibus propelled by electricity to carry 26 persons. In appearance it is very like the ordinary tramcar, but it does not require metals to run upon, and it is constructed to give each passenger 4in. more room than the horse-drawn omnibuses. This has been built for the London Electric Omnibus Company, who anticipate having 125 similar conveyances running in the London streets at an early date. In the same class there are shown an electrically-propelled cab, and a victoria to carry two persons. In the class for vehicles propelled by petroleum motors Sir David Salomons exhibited a very neat carriage for four persons propelled by benzoline; but though it worked admirably, Sir David has not got over the two drawbacks of benzoline carriages—the disagreeable smell of the benzoline and the extreme vibration when the vehicle is stationary. There were, of course, a number of other steam and benzoline vehicles.

The Royal Society.—The first conversazione of the Royal Society was held on Wednesday night. There was, of course, a distinguished company present, and the exhibits were even more varied and interesting than in past years, and some of the demonstrations and experiments were extremely striking. So far as the exhibits connected with magnetism and electricity are concerned, Prof. Ewing showed a new apparatus for measuring the magnetic permeability of iron and steel. Prof. Roberts-Austen showed several curious experiments which are modifications of one recently described by Margot, of Geneva. A fine wire of aluminium is heated to no less than 400deg. above its melting point, but the wire nevertheless remains intact. This is owing to the formation of a fine film of alumina on the surface of the wire, and the metal, being very light, does not run into globules, as it might be expected to do. As the molten wire has a current passing through it, it will, if approached by a similar wire or by a magnet, enable all the effects of mobile conductors carrying currents to be illustrated. One experiment showed that the molten wire can even be twisted on itself without rupture, and the effects of a tenacious thread of molten metal moving in response to electrical influences are very singular. Mr. E. H. Griffiths showed a novel self-testing resistance box and bridge; Mr. F. W. Burstall showed a resistance-box, standard coils, and wire bridge, and bare wire resistance thermometers for use in vessels under high pressure. Mr. Joseph Goold exhibited a new synchronising sound generator, which is a vibrating bar having the pitch or vibration period of the note to be elicited. The separate partial tones can thus be developed singly with remarkable power and sweetness, and the clear gong-like note of the bars could be heard in all parts of the crowded rooms. These appliances have already led to the further curious discovery of vibration axes and vortices, examples of which were exhibited. Prof. Boys's exhibit was a geometrical arrangement of wall brackets and steady blocks, likely to be of great service in conducting physical experiments. The Cambridge Scientific Instruments Company exhibited a very delicate bifilar pendulum in action, designed by Mr. Horace Darwin, for observing and recording slow tilts and pulsations of the earth's crust, by whatever cause they may be produced. It is a modification of that used by the Messrs. Darwin in 1881 at the suggestion of Lord Kelvin. Prof. Dewar is not a frequent exhibitor at the Royal Society soirées. Last night he projected on the screen by means of the electric lantern some of his famous experiments with liquid air. Prof. Worthington and Mr. R. S. Cole showed instantaneous photographs of splashes taken each with an electric spark giving an exposure of less than three-millionths of a second. The spark could be so timed as to pick out any desired stage of the splash. In this way the progress of a great variety of splashes has been followed in minute detail. Especially interesting are those which illustrate the formation of a bubble. Prof. Hartley exhibited photographs of spectra illustrating his discovery of the presence of the rare metal gallium in the Middlesbrough iron ore Of course the "new photography" was much in evidence. Mr. Sydney Rowland exhibited a series of Röntgen photographs, and the process was demonstrated by Mr. Campbell Swinton. Several of the distinguished visitors seized the opportunity for having their hand and arm bones "skiagraphed," and a number of pictures previously taken were thrown on the screen by the electric lantern. These included a view of Lord Salisbury's hand, exhibiting, said the demonstrator, "distinct marks of incipient gout." Mr. Herbert Jackson gave a beautiful demonstration of the use of phosphorescent materials in rendering Röntgen rays visible. For the rest there was an opportunity of comparing Mr. Ives's and Mr. Lippmann's methods of colour photography, and a quantity of the mangled gas-bottles, the results of experiments on steel gas cylinders, exhibited by the Gas Cylinder Committee lately nominated at the request of the Home Office, should have been of practical interest to lecturers using limelight lanterns.

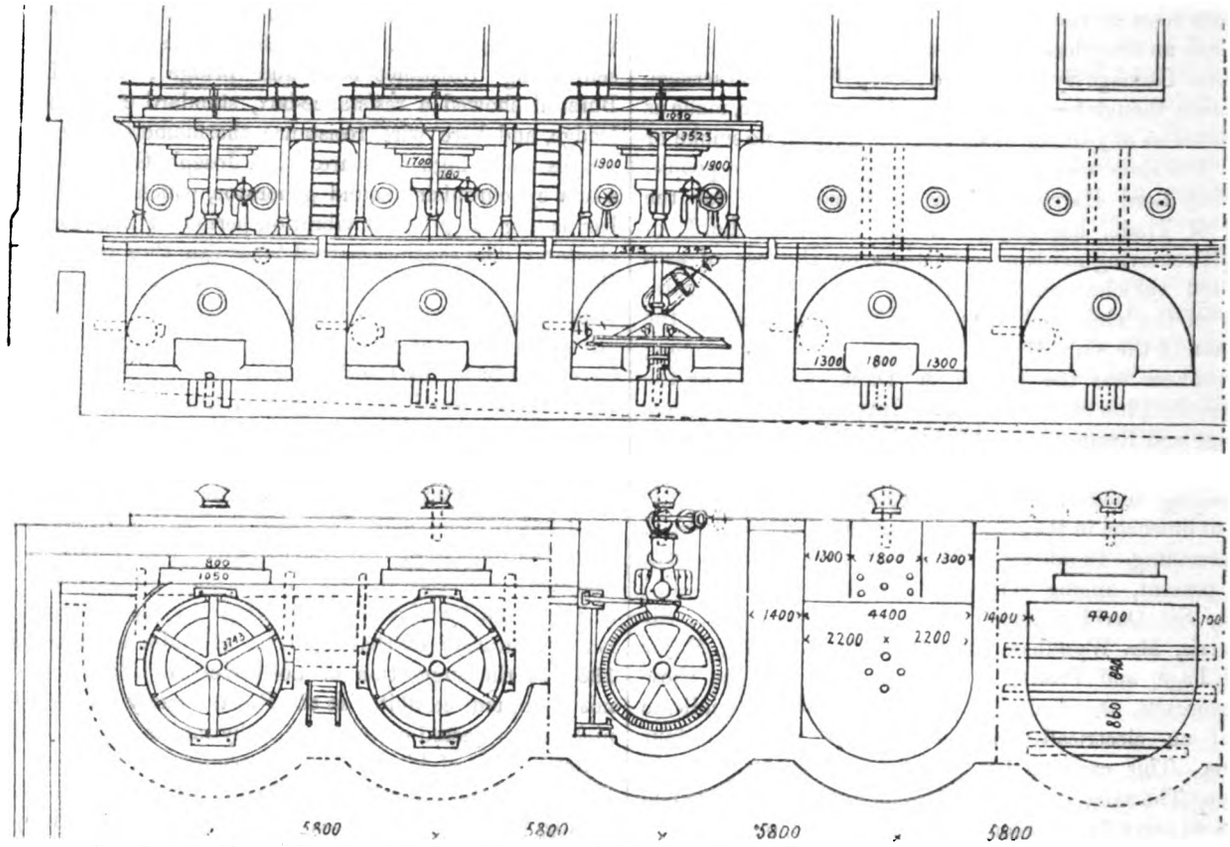
THE BRITISH ALUMINIUM WORKS AT FOYERS.

(Concluded from page 459.)

The arrangement and the details of the turbines can be seen from the plan, elevation, and section of the general arrangement of the plant (Figs. 7, 8, and 9). As will be seen, the shaft is vertical. It rests on a lens-shaped footstep of hardened steel. The control of the turbine is effected by the hand-wheel on the left side of the machine, while the handle controlling the sluice-valve on the pipe is on the right. No governors are provided, as the load is fairly steady and can be regulated by attention to the furnaces. The turbines were designed and manufactured by Escher, Wyss, and Co., of Zürich.

The large dynamos, five in number, have each an output of 7,500 amperes at 64 volts. They are direct coupled to the vertical shaft of turbines, and run at a speed of



FIGS. 7 AND 8.—Plan and Elevation of the General Arrangement of the Power Plant at Foyers. The Dimensions are in Millimetres.

150 revolutions per minute. The 480 kilowatts output is guaranteed by the makers under the following stringent condition: each machine is to be run continuously 24 hours a day for seven consecutive days at full load, without any sparking at the brushes even when the load is suddenly varied, and also without undue heating at any part of the dynamo. The general view of a dynamo as it appears when erected is shown in Fig. 10.

The construction of these machines can be seen from the section (Fig. 11). The magnet frame is of soft cast iron, and is supported on lattice-work columns from the floor of the engine-room. The machine has 24 poles, so designed that the magnetic coils, each of which weighs some 3cwt., can be slipped on easily. The iron is worked considerably above the saturation point so as to neutralise the back magnetisation of the armature at varying loads.

The armature has an external diameter of 8ft. The core is built up of soft-iron stampings carried on a strong cast-iron spider. The winding is on the multipolar drum winding system, with parallel connections at the ends. There are special equalising connections between all the bars of equal polarity, so as to prevent equalising currents passing through the sections of the armature winding if the voltage generated in the various sections should not be exactly the same. The bars are placed on the periphery of the iron core, and are held in place by passing through holes in five sheet-brass discs, which are specially inserted into the armature body for this purpose. Thus no binding wires are necessary, but they are nevertheless used as a special security. Additional insulation is used where the bars pass through the brass discs. Some such method of resisting the centrifugal stresses must be adopted in such large-diameter armatures running at a speed, like in the present case, of 3,750ft. per minute. Fig. 12 shows a finished armature of this type, but of rather smaller size.

The commutator has a diameter of 6ft., with a surface 15in. long. It is of special hard bronze, and insulated with mica. It has 216 segments. (Machines of the same type have been running continuously for nearly four years at Neuhausen, and up to the present moment no appreciable wear on the commutator has been noticed). Besides this main commutator there are two auxiliary commutators on the armature, for the purpose of making the armature-bar connections. Thus the main commutator can be removed and renewed, if necessary, without disturbing the armature winding.

A very important feature with a machine for large currents is the brush arrangement, and therefore special care has been taken in designing it. There are two large rings of solid cast copper, which are fastened horizontally

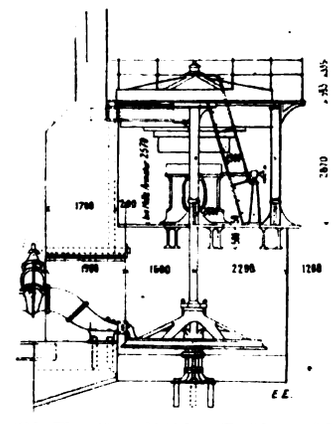


FIG. 9.—Side Elevation of 700-h.p. Turbine and Dynamo.

to a cast-iron support with bolts and insulating bushings. Each of the rings carries 12 massive brush-holder studs of copper-bronze. Each stud carries five brushes, so that there are 120 brushes all around. The dynamos have been supplied by the Oerlikon Company, and were designed

Digitized by Google

by Mr. Emil Kolben, who kindly showed the machines while in course of construction to our special correspondent at the Verband meeting last year. The details of the machines now published were then kindly promised to us. We gave a little information about the design of these dynamos in the "Interview with Mr. Kolben," published on August 30, 1895.

The whole of the British Aluminium Company's plant will be placed under the superintendence of the resident engineer, Mr. C. T. H. Weiss, A.M.I.C.E., who has also charge of the erection of the electrical machinery, and will act as general manager at Foyers. The civil engineering in connection with the tunnel, pipe line, and general arrangements has been placed in the hands of Mr. W. Graham, who has superintended the work throughout.

The landing stage has had to be enlarged to meet the requirements for landing the heavy part of the dynamos, and the approach to it has also been widened by blasting.

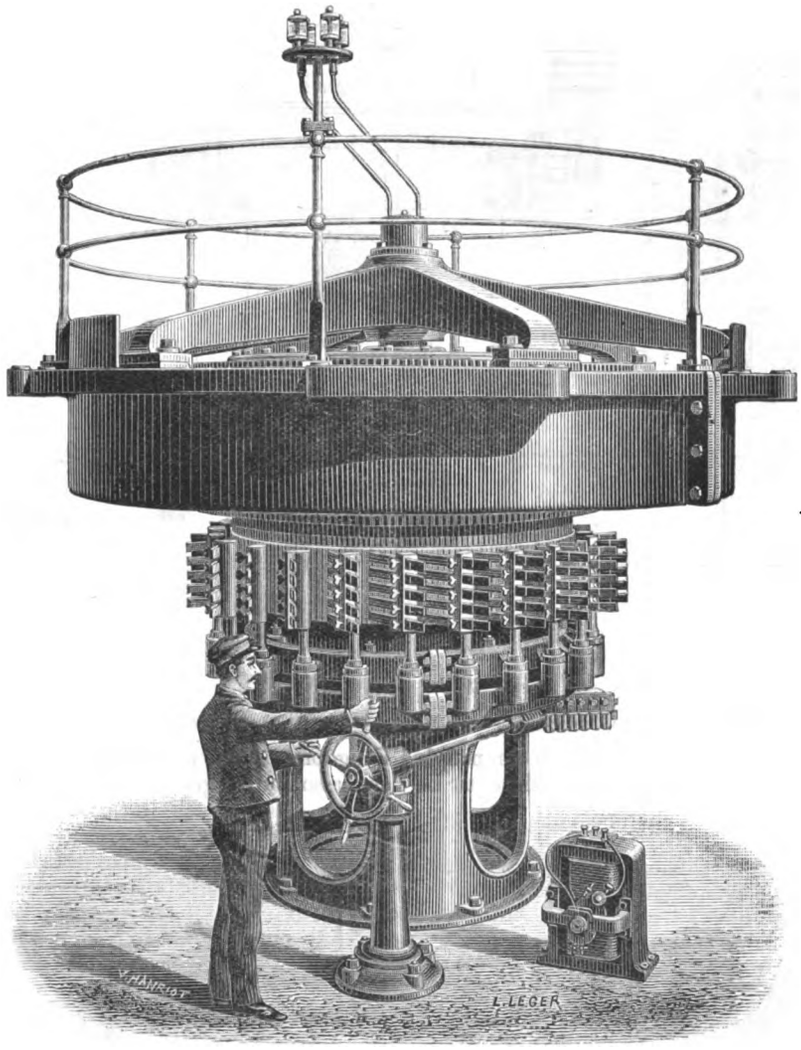

FIG. 10.—Perspective View of 480-K.W. Direct-Current Dynamo used at the Aluminium Works at Foyers.

A general view of the landing stage, as far as now completed, is shown in Fig. 13.

As explained above, the process for making aluminium at Foyers will be the same as that so successfully used at Neuhausen—hence the following details of the process used there, taken from Mr. W. Richards's valuable book on aluminium, will be of interest to our readers. The operation is begun by placing copper broken into rather small pieces in the crucible. The carbon anode is then approached to the copper, which is quickly melted by the current. The bath of fluid copper then becomes the negative pole, and ore is immediately fed into the crucible. It also is soon melted, and floats on the top of the copper. The electrolysis now proceeds, care being taken that while the anode dips into the molten ore it does not touch the molten cathode. Particular stress is laid on the economy of keeping the distance between the electrodes small, the reason given being that the space between, being filled with a layer of badly conducting molten ore, offers a resistance which increases with the distance, and although resistance is necessary, in order that the current should produce heat, it is not economical to have more heat than necessary to melt the ore, the work of separating the metal from the oxygen being chiefly done by the electrolytic action of the current, and not by the high temperature. In practice, this intervening space is not over three millimetres ($\frac{1}{10}$in.) The workman in charge, by watching the indication of the ampere-meter, is enabled to maintain the anode at its proper distance without any difficulty; it is proposed to do this regulating automatically by means of an easily constructed electrical device. The oxygen liberated gradually burns away the anode, it being found that about 1lb. of the anode is consumed for every pound of aluminium produced. After the operation commences, the alumina is introduced as required, and cryolite is added to reduce the resistance of the bath of fluid ore.

The plant at the Rhine Falls as now operated consists of the 300-h.p. turbine used since 1888, two 600-h.p. Jonval turbines, and five others of 610 h.p. The water rights obtained by the company in 1887 from the Canton Schaffhausen allowed it to take from the Rhine 700 cubic feet of water per second, which at a fall of 20 metres (65ft.) give an effect of 4,000 h.p. The combined power of the above turbines exceeds this, but one is always kept at rest and only seven regularly run. The 600-h.p. dynamos are also of the Oerlikon make, and at 150 revolutions give a steady current of 7,500 amperes at 55 volts. This plant, working to its full capacity since the middle of 1893, turns out daily 5,500lb. of aluminium. The financial prosperity of the Neuhausen works is shown by the fact that the dividends paid have risen from 8 per cent. in 1892 to a steady 10 per cent. ever since, although the price of the aluminum produced has fallen considerably.

The British Aluminium Company have kindly sent us an

Digitized by Google

interesting pamphlet on the uses of aluminium and its alloys, from which we learn that the aluminium made at Foyers will be cast into ingots and sent to the company's foundry and rolling mills at Milton, Staffordshire, to be worked up into forgings, sheets, rods, bars, tubes, etc. This industry will prove, therefore, when in full working order, essentially British in character, the power and all the raw materials being obtained within the United Kingdom. The properties of the metal and its alloys are also fully given. The following brief *résumé* may be of interest. The tensile strength of castings in aluminium of about 98 per cent. purity is 5 to 5½ tons per square

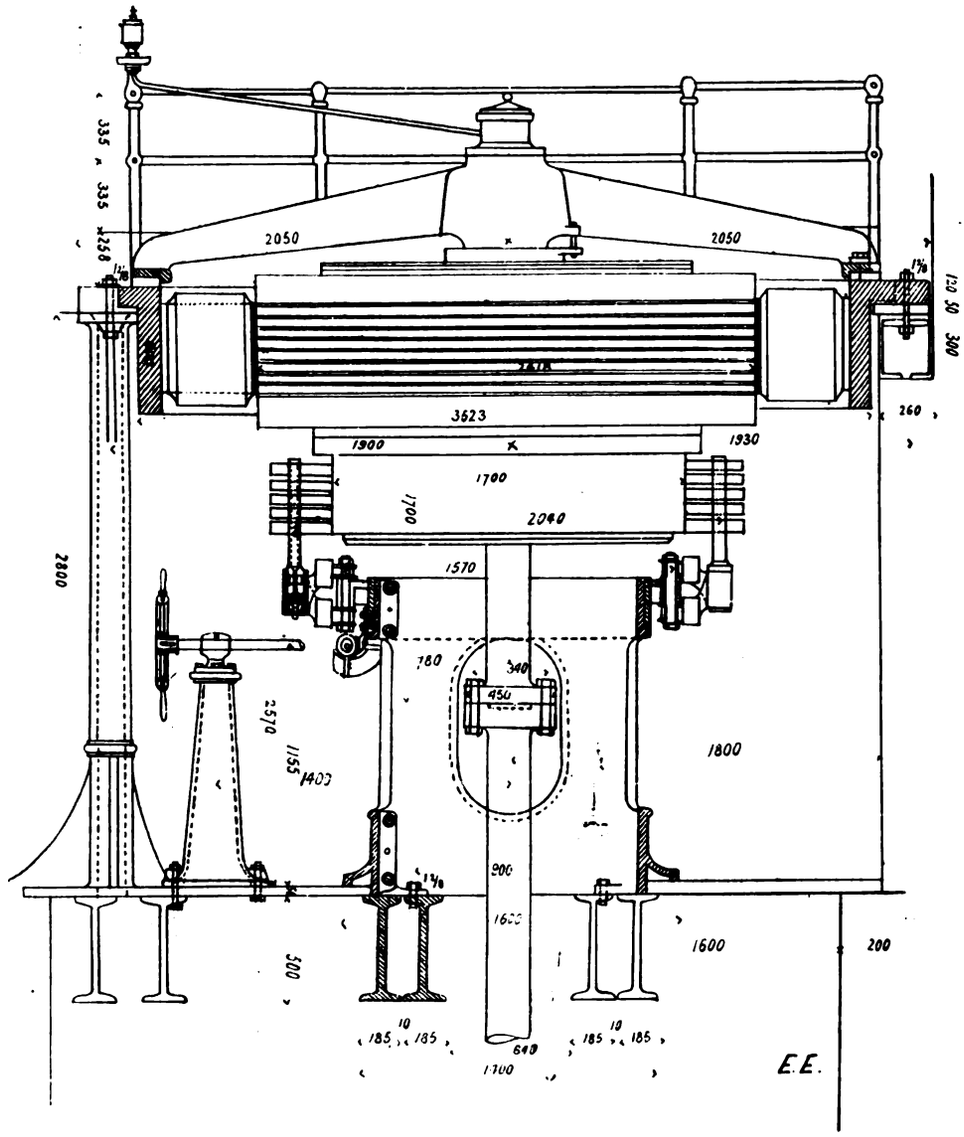

FIG. 11.—Detailed Sectional Elevation of the Oerlikon 480-K.W. Dynamos Installed at Foyers. The Dimensions are in Millimetres.

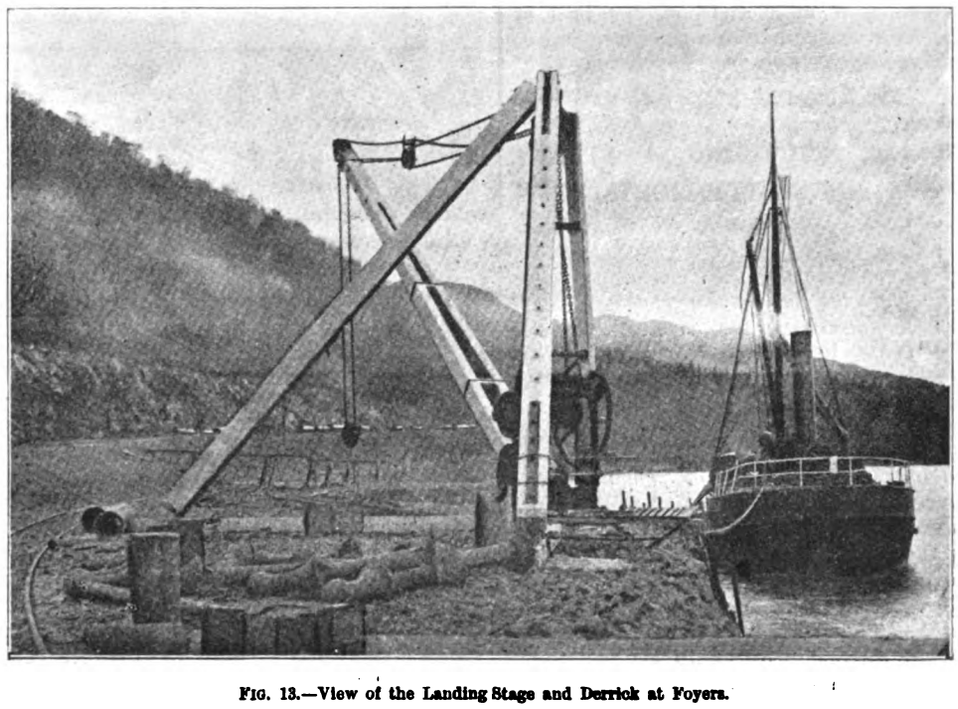

FIG. 13.—View of the Landing Stage and Derrick at Foyers.

Digitized by Google

inch, with an elongation of about 2 to 3 per cent. (like ordinary cast iron). The specific gravity of pure aluminium is:

Cast in sand	2·56
Cast in metal moulds	2·60
Hammered or rolled	2·67
Hammered and drawn (wire)	2·71

The weight per cubic foot of cast aluminium is 158·90lb. The weight per cubic foot of rolled aluminium is 169·50lb. A cubic inch of cast aluminium weighs 0·092lb. Aluminium is practically non-magnetic. The specific resistance of the pure metal is 58·59, as compared with copper of 100. Pure aluminium is less affected by dry and damp air at ordinary temperatures, as well as at red heat, than any other metal, with the exception of gold and platinum. It also resists well the action of most of the acids met with in commercial processes.

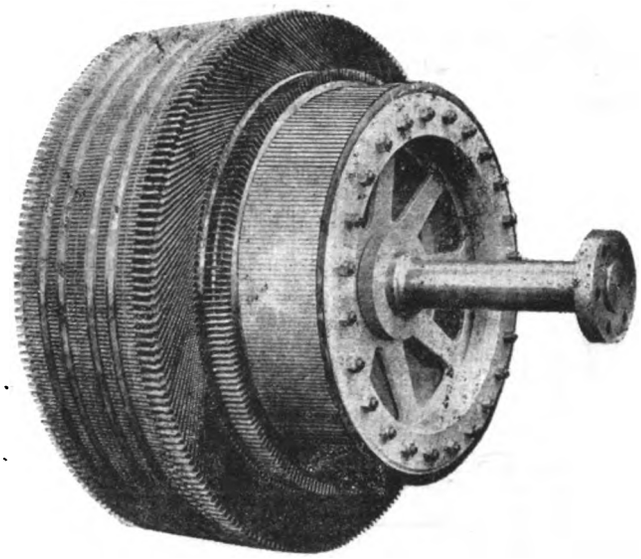

FIG. 12.—View of the Armature of an Oerlikon Multipola Dynamo.

The mechanical processes of forging, rolling, wire-drawing, spinning, etc., can be carried out with ease in the pure metal, and there is little difficulty in casting the metal. The melting point is 1,160deg. F., as no fluxes are required to prevent oxidation as when melting most metals.

A comparison of the present market prices shows that aluminium is at present, bulk for bulk, 5,433 times cheaper than platinum, 5,109 times cheaper than gold, 91 times cheaper than silver; that wolfram manganese, nickel, German silver, gunmetal manganese, and phosphor bronzes stand higher in price, and that aluminium can now successfully compete with copper, tin, and even brass.

AN APPARATUS FOR PROVIDING A STEADY PLATFORM AT SEA FOR SEARCH-LIGHTS, ETC.

BY BEAUCHAMP TOWER.

The author commences by stating that many intelligent people, when considering this subject for the first time, have suggested that this object may be attained without difficulty by hanging the to-be-steadied object in gimbals and attaching a good heavy weight underneath. They point to the bowl of the mariner's compass, or to the swing table commonly used on board yachts, as examples of objects steadied by these means. He then showed the fallacy of the idea that a pendulum hangs perpendicular on board a ship in a seaway. The swing table and the mariner's compass do not maintain a constant attitude with the horizon in a seaway, as looking along the top edge of either at the horizon will prove.

The late Mr. William Froude, in a paper on "The Rolling of Ships," read before the Institution of Naval Architects in 1861, describes the following experiment which he tried: He took an ordinary ring lifebuoy, and on it he erected a tripod, from which he suspended a plummet. When this was floated on waves, he observed that the plumb-line hung perpendicular to the wave-slope under all conditions, even in the extreme case of a curling-over wave breaking on a beach. In short, he found that a plumb-line afloat on waves departs as much from the vertical as the surface of the wave does from the horizontal, and cannot, therefore, be depended on, under those conditions, as an index of the true perpendicular. The author then proceeded to describe an apparatus for giving absolutely perfect steadiness to search-lights, machine guns, or other objects, even on a small, quickly-rolling vessel in a very rough sea.

A search-light projector throws a narrow ray of light not much more than a degree wide; and, in order that it may be of use for detecting the approach of torpedo boats or other objects at night, it must be held so steady as to

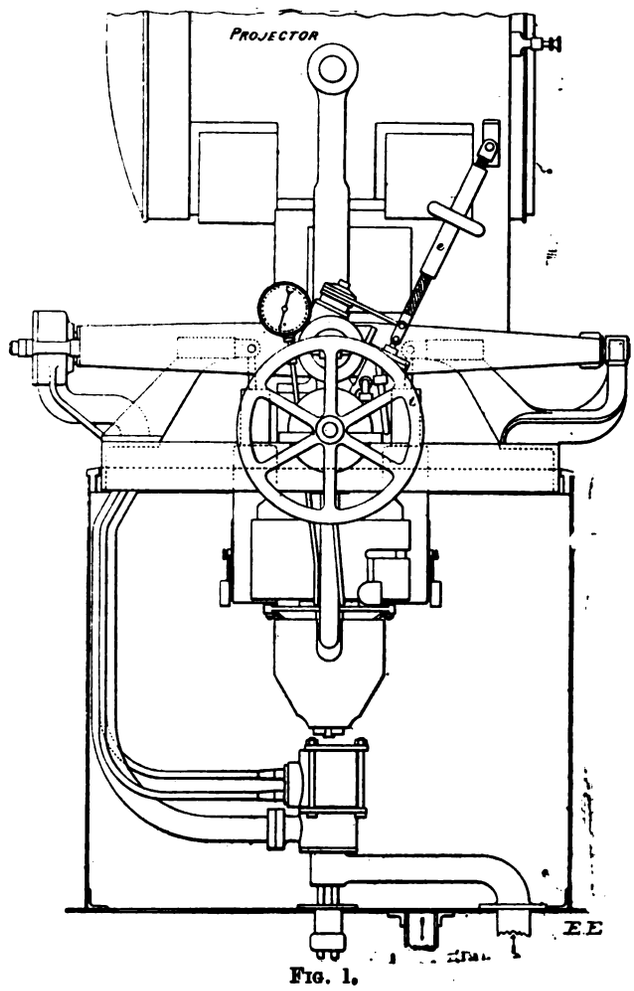

FIG. 1.

have no angular motion in a vertical plane comparable with the angle subtended by the ray of light, or it is impossible to keep the object in the field of illumination.

In this apparatus the platform (see Figs. 1 and 2), or part to be kept steady, and to which the search-light is attached, is hung in gimbals, so as to have angular freedom in every direction, in the same manner as the bowl of a mariner's compass. The gimbals are supported on a turn-table which runs on wheels on the top edge of a tank or pedestal, so that the light may be trained to any point of the horizon. At each of the four corners of the platform is fixed a cylinder, *k*, having a ram or plunger projecting upwards out of it, connected by a rod with a point, *e*, fixed relatively to the ship. If one of the rams is forced out of its cylinder by water pressure, it will cant the corner of the platform to which it belongs downwards in the gimbals, so that, by regulating the admission of water pressure to the four cylinders, the attitude of the platform in the gimbals can be controlled. This is done by the gyroscope revolving in a horizontal plane on a ball-and-socket bearing, supported on the centre of a cross-shaped frame which connects the bottoms of the four cylinders. The bodies of these cylinders project downwards

* Abstract of a paper read before the United Service Institution.

Digitized by Google

from the platform, and are connected together by plates in such a way as to form a square cell within which the gyroscope revolves. The ball-and-socket bearing allows the gyroscope freedom to wobble or depart from the horizontal plane in every direction through an angle of about 3deg.

A supply of sea-water at the rate of 50 gallons per minute, and having a pressure of 100lb. per square inch, is pumped by a donkey engine to the platform, which it reaches by passing through the interior of the gimbal ring. This is made hollow for the purpose, and is provided with watertight oscillating joints in its bearings. The water can thus pass without leakage through the moving parts of the gimbals to the platform, and is conducted by pipes, *p* (Fig. 2), to the ball-and-socket bearing of the gyroscope, which is made hollow so as to provide a passage for the water into a chamber in the interior of the gyroscope. From this chamber passes two radial passages, *r r*, to the outside rim of the gyroscope, where they terminate in tangential jets, *t t*. These two jets are each $\frac{3}{16}$in. in diameter, and by their reaction cause the gyroscope to rotate at about 1,500 revolutions per minute. About one-third of all the water escapes through these tangential jets, and is used in giving the gyroscope rotation. The remaining two-thirds pass upwards from the chamber, and issue from a jet $\frac{3}{8}$in. diameter, which forms a prolongation of the upper axis of the gyroscope. It is this axial jet which provides the motive force for the controlling cylinders, *k k*, of the platform.

In order to make the gyroscope seek to revolve in a horizontal plane, four small pendulums are hung outside it. Each of these pendulums has a horizontal arm projecting from it; on the end of each there is a small wheel, *w*, which rests and presses lightly on the upper rim of the gyroscope. If the gyroscope is revolving in a horizontal plane all these pendulums press on it equally with their horizontal arms, but should the gyroscope be out of the horizontal plane, then one pendulum presses more and one less hard, in such a way as to cause it to seek the horizontal plane. Of course, these pendulums are subject to the disturbing forces of the wave-motion, as all pendulums are on board ship, and consequently do not tend to hang truly perpendicular to the horizon during the passage of a wave, but the gyroscope yields too slowly to the unequal pressure of the pendulums to take notice of these disturbances, which last only during the passage of a wave. Its position is that due to the mean of all the forces acting on the pendulums during a long period of time, which mean is the true perpendicular force of gravity.

We thus have a gyroscope revolving in a horizontal plane and throwing a truly vertical jet out of the axial jet nozzle. Immediately above the axial jet, and about $\frac{1}{2}$in. from it, are four open-mouthed ports, forming in a circle, divided by radial divisions into four equal sectors; their open mouths are directed downwards towards the axial jet. The passages, of which they form the terminations, communicate each to one of the four cylinders, *k*.

If the platform is truly horizontal, the axis of the axial jet passes through the centre of the circle containing the four ports, and the jet is equally distributed between them, but should the platform be the least bit out of the horizontal plane, some of the ports receive more of the jet than others, and this causes an inequality of pressure in the cylinders which cants the platform into the horizontal plane. The reason for using the jet as a connection between the gyroscope and platform is that it enables the gyroscope to powerfully control the platform and yet suffer no reaction on itself. A very small force would be sufficient to disturb the gyroscope from its horizontal plane of rotation, but no force can be communicated to it from the platform, as it makes no difference to the gyroscope what the axial jet strikes against after it has left the nozzle.

The first practical machine of this type was fitted up on a small steam yacht 50ft. long and 11ft. beam, and subjected to a laborious course of experiment, extending over about two years. It was experimented with by the officers of H.M.S. "Vernon" as a means of mounting search-lights, and by the officers of H.M.S. "Excellent" as a means of mounting machine guns. In both cases their reports showed that the machine answered the purpose for which it was designed perfectly. After these experiments a machine for mounting a 24in. search-light projector was ordered by the Admiralty to be fitted to H.M. gunboat "Bloodhound," tender to H.M.S. "Vernon," for further experiment, which showed that the machine could be depended on to keep a search-light ray absolutely steady on a small vessel in a heavy sea. Since then, Sir W. G. Armstrong, Mitchell, and Co. have taken up the manufacture of these machines, and are fitting it to the torpedo destroyers "Swordfish" and "Spitfire," which they are constructing for the navy. They are also supplying these machines to the order of the Chilian Government for a cruiser building at Elswick. There would be no difficulty in mounting the smaller class of quick-firing guns on these machines, of

PLATFORM.

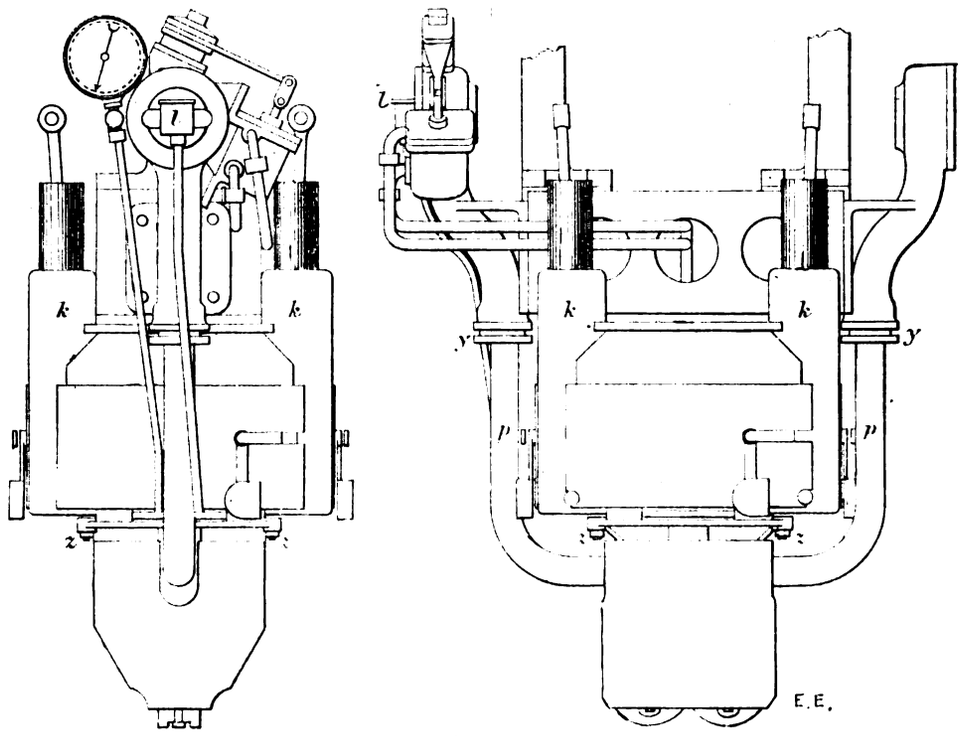

FIG. 2.

Digitized by Google

course specially designed for the purpose; and on a small vessel, in which the motion is very quick and the difficulties of accurate shooting great, it ought to be very effective. For larger guns, an automatic firing apparatus has been designed for attachment to this machine, so as to fire the gun electrically at the right moment in the roll.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XXX.

(Specially Contributed.)

Before sketching briefly the progression of invention in this class of magneto machinery, there is just one other experiment I want to show you. Fig. 1 shows a galvanometer which, for ease in making such experiments, instead of terminals, has contacts made by little mercury-cups in the base of the instrument, into which the ends of a conductor are brought. W represents a conductor

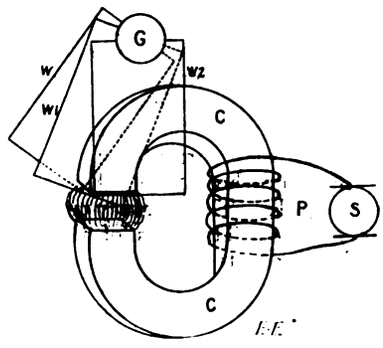

FIG. 1.

of insulated wire of a number of turns, the ends of which are taken into the mercury-cups of the galvanometer. I can swing the coil backwards and forwards without breaking contact with the galvanometer. Arrange this coil and galvanometer so that the coil can be swung backwards and forwards through the air-space of the core, C C. When connection is made with the source by means of the primary wire, P, around C C, lines of force are generated in C C and pass through the air-space, bulging out to cover more area according to the length of the air-space. For our purpose, suppose the lines go through the air, as shown.

First, let the conductor in connection with the galvanometer be in the position W.

If I make and break contact of the primary with source, no indication is shown by the galvanometer, because *none of the lines of force* loop, thread, or link—whichever term you like best—the coil W.

Second, let the coil with the galvanometer be in the position W_2. Now, when I make the primary contact, I get a deflection on the galvanometer, and the needle goes back to zero if I keep the contact made. Let the needle get back to zero, and then break the contact. The indication of the galvanometer is in the opposite direction to what it was before, but equal in value. We take it, then, that when making contact the lines of force looping W_2 caused a current flow of a definite magnitude, and when contact was broken there was an equal current flow, but in the opposite direction.

This is the common way of looking at the matter, but I would prefer to say that the looping of a coil by lines of force changes that coil from a normal condition to a different condition, and that when the lines are taken out or unlooped from the coil it returns to its normal condition. However, there is no manner of doubt but that the looping and unlooping of equal numbers of lines of force around a coil does produce equal but opposite effects.

Third, keep primary contact closed, and swing coil from position W_2 to position W; we get the same effect on galvanometer as when contact was broken.

Fourth, keep primary contact closed.

Swing from W to W_2, and note effect on galvanometer.

Swing from W_2 back to W, and note effect on galvanometer.

The effects are equal and opposite.

Swing from W to W_1, and note effect on galvanometer.

Swing back from W_1 to W, and note effect on galvanometer.

Still the effects are equal and opposite, but the value is less than in the previous cases, because the coil has only been looped and unlooped by a part of the lines of force.

Lastly (I am supposing C not saturated in any of these experiments), double the turns of the primary, and thus double the number of lines of force.

Swing from W to W_2 and back from W_2 to W as before, and you will find the effect as indicated by the galvanometer doubled, because the coil W is looped and unlooped by double the number of lines of force.

Such experiments can be multiplied a hundredfold, and all tend to prove that the current in any given coil depends absolutely upon the number of lines of force looped around that coil. It is as absolutely certain that when we consider the effect on a coil moving through a magnetic field we must consider the phenomena occurring both on looping and on unlooping (linking and unlinking seem to meet recent approval) of the lines of force. This has not been done by writers except in one or two cases. "Linking" and "linkages" are becoming common terms, and thus we have great hopes for the due recognition of unlinking.

From Faraday to De Meritens.—All the earlier machines had permanent magnets for the field magnets, hence are called magneto machines. This type of machine has now almost entirely given place to those having electromagnets as field magnets that I shall trouble little more than to briefly describe a few machines bridging, as it were, the time for half a century from the time of Faraday, and bringing us to that time when a marvellous development of electrical work took place. Not only did these early designers produce machines that acted as generators like those of Pixii and Saxton, but they designed motors, and endeavoured to transform electrical back again into mechanical energy. There are four machines of this latter kind that I would like to mention: Davenport's, because he was about the first—he ran a printing press with his machine; Sturgeon's, because he applied his to domestic uses—in fact, to a roasting-jack; Jacobi's, who applied his to the propulsion of a boat on the Neva; and Davidson's, which was used to propel a railway car.

Davenport, Sturgeon, Jacobi, and Davidson.—Davenport's machine is shown in Fig. 2, where C shows

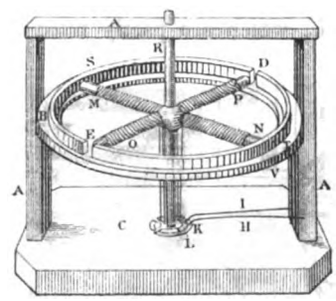

FIG. 2.

the base-piece, A, A, A the framework; H and I are conductors from a battery connected to copper contact-pieces, K L, in the form of segments of circles and corresponding in number with the magnets to be mentioned. The contact-pieces are around the shaft, with air-spaces between each other and the shaft. The alternate copper contacts are connected to the zinc pole of the battery and to the copper pole. Wires go from the contact-pieces to the electromagnets above. These magnets, M, N, O, P, are shown round the vertical shaft, R, which turns on pivots. The stationary magnets, S T, were either permanent, as shown, or might be electromagnets, with north and south poles at D and E respectively.

I ought, perhaps, here to explain that a dynamo machine is a reversible machine. Thus, if I link lines of force through a conductive circuit, I get an electric current in that circuit. Generally, I manage that linking by carrying

Digitized by Google

the conductive circuit into and out of the magnetic field, and thus use mechanical energy. If, however, I send a current through a conductive circuit which is in a magnetic field, the conductive circuit by the current creates its own magnetic field. The two fields react on each other, and if one field is fixed in space, the other moves towards a space wherein there exists no field but that it takes. This motion gives us mechanical energy. A machine which some part is mechanically moved in order to get a current of electricity is called a generator; one in which a part moves because of the reaction between two fields is called a motor.

These machines I am now describing are motors. Davenport had his fixed permanent magnets, S T, with their fields. He sent a current through A I, around his electromagnets, M, N, O, P, and thus created their fields. The reaction between these fields causes the axle, R, with its radiating magnets, to spin round.

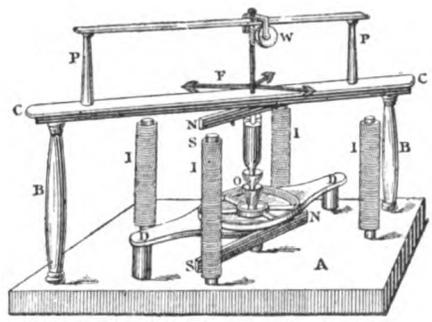

FIG. 3.

Sturgeon's apparatus is shown in Fig. 3. The base, A, carries pillars, B B, cross-piece, C C, with pillars, P P, cross-piece, and wheel, W. A central vertical shaft runs in collars, as shown, and passes through and is fixed to two circular channels, one above the other, also through a cross-piece, D D, supported by pillars. On D D are four quadrantal metal plates separated by air-spaces. Two compound bar magnets, N S, S N, are carried near the top and bottom of the shaft, as shown. Electromagnets, I, I, I, I, are fixed as shown. Each straight core carried six insulated coils. Each set of extremities of these copper wires is soldered to one stout copper wire; hence the extremities of the 24 coils terminate in eight of these latter wires, four of which proceed from the lower extremities of the coils, and are soldered to four quadrantal metallic plates, one to each. The other four stout wires proceed from the upper parts of the coils and terminate by proper connections in the circular channels, which are partly filled with mercury.

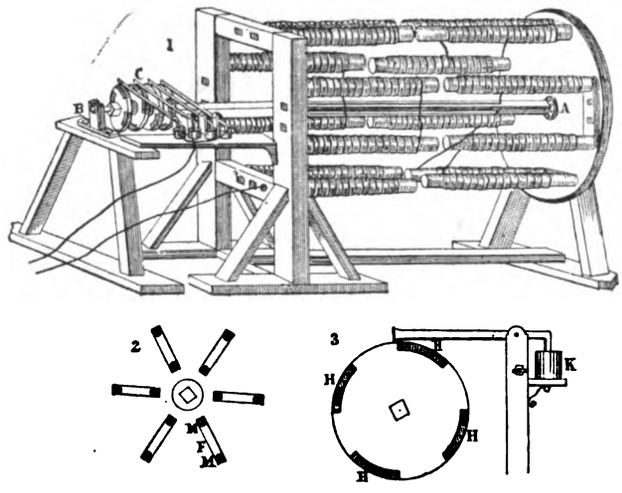

FIG. 4.

Through the sides of the channels pass four metallic stems, two through each, their inner extremities being in contact with the mercury in their respective channels. The stems of each pair are placed at 90deg. from each other, and the whole at right angles to the shaft. The right angle which the upper pair forms is on the opposite side of the shaft to that formed by the lower pair. From each stem hangs a metallic wire, reaching obliquely to its respective quadrantal plate on the cross-piece, D D, which maintains a connection between these plates and the mercury in the circular channels, transferring the electric current from one plate to another, and consequently from one coil to another in their progress of revolution. To prevent the figure being distorted, none of these connecting wires are drawn. Battery connections were made through the cross-piece, D D, and properly connected the electromagnets were magnetised in succession. This done, N S, S N and shaft rotated, and this rotation was conveyed to a roasting-jack.

Jacobi's apparatus (Fig. 4) was used to propel a boat on the Neva. It was rather cumbrous, but Jacobi himself, and soon after Stoehrer, of Leipsic, and Wagener, of Frankfort, greatly improved on the original, Stroehrer claiming to be able to get 45 h.p.—to propel a train of wagons with the usual complement of passengers from Leipsic to Dresden on the railroad for 6s. The fixed and revolving magnets of Jacobi's machine are shown at 1 (Fig. 4) in the illustration. He used electromagnets and a commutator to reverse the poles of the fixed magnets. 2. The commutator consisted of four pieces of copper on the axle, connected electrically two and two. The pairs were separated by a hollow axle of wood. The edge of each plate was divided into eight parts, four of which were hollowed out and filled with ebonite, the surface being flush. The copper plates are shown (No. 1, Fig. 4) arranged on the axle so that the sectors of wood and metal alternate. C C are contact-pieces or brushes to carry current from the battery. No. 3 shows one of these brushes better, the short end dipping into a mercury-cup, K. The mercury-cups were electrically connected by a wire. The coils of the moving magnets were electrically connected to the pairs of plates of the commutator. The coils of the fixed magnets ended in a mercury-cup connected to one pole of the battery, the other pole being connected to one of the mercury-cups, K, of the commutator.

PHYSICAL EXPERIMENT IN RELATION TO ENGINEERING.*

BY DR. ALEXANDER BLACKIE WILLIAM KENNEDY, F.R.S., M.I.C.E.

It has been the expressed wish of the gentleman in whose honour the "James Forrest" lectures have been instituted, that they should deal with the relation of various sciences to our own profession. To those of us (and they are many) who have long enjoyed his friendship, and who are to some extent familiar with the extent to which our profession is in his debt in matters innumerable, it is practically a duty to meet his wishes in such a matter. But it must be acknowledged that the duty—as regards the lecturer—must grow every year more difficult, as the field becomes limited by his predecessors; and even at present it was with no little nervousness as to the selection of a subject that I accepted last year the invitation to give this lecture in 1896.

There is perhaps no science, except those in the biological group, of which it might not be argued, with some degree of plausibility and reasonability, that the profession to which we all belong was a direct application. The sciences of mathematics and of physics, of chemistry and of geology, concern themselves with the exact statement of the nature and relations of facts and phenomena with which we as engineers have continually to concern ourselves. But the point of view of the purely scientific investigator and of the engineer, in regard to these facts and phenomena, are no doubt very different. In rare and exceptional cases one man can play both *rôles*, but this happens so very seldom that for all practical purposes they may be regarded as distinct from each other. And no one who is not terribly narrow—on one side or the other—would deny that either might form a worthy life-work for any man, however high his aims or ambition.

I excepted just now the biological sciences from those with which engineers were directly in touch. But, in spite of this, I confess that I have had a great wish for years past to devote some time to the working out of a theory of evolution in relation to engineering progress. I cannot help thinking that there is something in relation to things inorganic which closely resembles the position of natural selection in the organic world. The struggle for existence, which too obviously exists among engineers themselves regarded as organic beings, seems also to exist

* The "James Forrest" lecture delivered before the Institution of Civil Engineers, Session 1895-1896.

Digitized by Google

in effect among engineering productions. There is also among them a survival of the fittest, and the laws which determine what is the fittest at any time, and how the standard of fitness alters as time goes on, are probably capable of fairly exact statement—in correlation with the laws of general human progress—at any rate they are very well worthy of examination. This biologico-engineering investigation would be no doubt rendered more difficult by the fact that artificial selection continually comes in to help and accelerate, or it may be to hamper and impede, but in any case to modify, the inorganic equivalent of natural selection. I have found this whole subject a most tempting one, full of fascination, and to some extent also of surprises. But finally I felt constrained to leave it, at least as far as this lecture is concerned, to someone—some fortunate person—whose mind was not so overcrowded with the innumerable details of everyday work as my own, or who was able, in spite of these details, to obtain at the same time a broad and comprehensive view of the whole subject from a point higher and more commanding than any that I seemed able to attain to. I hope that in some future year I may have the pleasure of listening to a "James Forrest" lecture in which "Evolution in Engineering" may be adequately dealt with. For myself I have found it necessary to be content with a much more limited subject, although one perhaps on which my own work gives me more right to speak, "Physical Experiment in Relation to Engineering."

We are all at this present time so familiar with the idea of physical laboratories—places in which physical experiment is carried out systematically and continuously, both for purposes of scientific investigation and of education—that it is hard to realise how very modern an institution the physical laboratory is. Until quite lately the most distinguished investigators worked in laboratories which they had made for themselves and which were essentially their own private studies. The Royal Institution laboratories—originally, I think, rather chemical than physical in conception—nevertheless became to a great extent physical, and in this way were early and notable extensions of the purely private laboratory, and happily exist still to furnish admirable physical work. But it is practically only within the last 30 years that physical laboratories, as we know them to-day, have come into existence. Thanks very much to this growth of experimental and physical teaching, we have now an army of trained physical investigators distributed all over the country, whose principal occupation (besides teaching) is the making of researches in experimental physics, and in this way contributing to our knowledge of the phenomena of the world around us, the phenomena which it is our business to turn to the "use and convenience of man." Not only this, but within the last 20 years there have come into existence numerous well-equipped engineering laboratories in connection with our technical colleges and schools. These engineering laboratories are, of course, simply physical laboratories modified in a certain special direction for our special purposes, and the investigations carried on in them are of the nature of physical experiment as fully and completely as those which are carried out in physical laboratories proper. The aim and scope of the two classes of experiment, however, differ considerably, as do their relations to our own work, and it will be my object this evening to put before you what, according to my own view, are the relations between these classes of experiment, and especially between each class and our own work. I need hardly say that I am bound to look at the whole matter throughout from the point of view of the engineer. I do not for a moment pretend that I am capable of taking up the position of the physicist, and, of course, I keep in mind also that I have to speak to an audience consisting essentially of engineers and not of physicists.

Physical experiment, so far as it has relation to our own profession, may fairly be considered to serve three distinct purposes. In the first place, from the purely academic or educational point of view, it is most important and helpful in the training of engineering students. (And it is well to remember that although a great many of us never were engineering students, nor had any opportunity of obtaining such training, yet the most conservative must now recognise that in the future our sons and successors must look on the student stage as being as essential as the pupilage or the apprenticeship.) Then, secondly, what may be called purely physical experiment is necessary to supply us with most of our most important constants, whether connected with the thermal properties of steam, the E.M.F. of a Clark cell, the density of water, the elasticity of steel, the coefficient for a *vena contracta*, or a thousand other matters of similar nature. Lastly, technical experiments, which are essentially physical experiments, but of a much more complex nature than those of the physical laboratory (although not on that account more difficult to carry out) are necessary for determining many matters, such, for example, as the efficiency of a dynamo, the steam consumption of an engine, the flow of a river, the resistance of a ship, or even the deflection of a girder under a moving load.

Let us consider, in the first place, the purely educative or academic type of experiment. Here the first requirement is the very simple one—which, indeed, may be served by an endless variety of experiments extending far beyond the limit of physics—that the student should learn first to see and to measure, and then to write down what he has seen and measured. Anyone who has had to do with laboratory work knows very well how necessary it is to differentiate in this fashion. The experiments require to be as far as possible quantitative rather than merely qualitative, but otherwise the simpler they are the better. It is unnecessary here to go into any details about them, but with a view to emphasising their importance it is worth while just to look for a moment at the sort of thing by which, in actual engineering work, these simple experiments may be said to be represented. Perhaps those whose work lies greatly in experimentation, like my own, know best how very hard it is to find assistants, unless they have been trained in a laboratory, who can be trusted at first even to take quarter-hourly readings of a steam-gauge or a counter, or any such duty, ridiculously simple and easy as it appears. To ask an untrained man to count the revolutions of an engine which has no continuous counter attached, or to read the dials of an ampere-hour meter, at exactly regular intervals of time, is merely to court disaster! The story is familiar of how Robert Houdin had so trained his faculty of general observation, that one look at a shop window would impress its contents on his mind more vividly and accurately than 10 minutes of hard looking would do in the case of an ordinary man. It is really just the same with the simplest of our observations. The ordinary mind does not naturally and at once see, and see accurately, the simplest thing that is before the eyes. One has to look, to exercise conscious mental effort, as well as merely to see, and we all of us require to be taught how to look, even in these most simple matters. And when the enforced looking has to be done at exactly a particular time and no other, the average mind is apt to find the whole process an intolerable burden, all the more because it is inclined to despise the work as being too childishly easy for consideration at the very time when it is failing to carry it out!

(To be continued.)

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

May 12, 8 p.m.—At the Institution, Great George-street, Westminster. Resumed discussion on "American and British Methods of Manufacturing Steel-Plate," by J. Head, and "Four American Rolling Mills," by S. T. Willmer.

Institution of Electrical Engineers.

May 8, 8 p.m.—At the Library, 28, Victoria-street. Students' meeting. "Single-Phase Transformers in Practice." By A. F. Berry.

May 9—Students' visit to the London Electric Supply Corporation's station at Stowage Wharf, Deptford. Train leaves Charing Cross at 10.20.

May 14, 8 p.m.—At the Institution of Civil Engineers, 25, Great George-street, Westminster. "The Influence of the Shape of the Applied Potential-Difference Wave on the Iron Losses in Transformers." By S. Beeton, C. Perry Taylor (student), and I. M. Barr.

May 15, 5 p.m.—Students' visit to Brook Green Works, Hammersmith.

Physical Society.

May 8.—"On Dielectrics." By R. Appleyard. "On the True Resistance of the Electric Arc." By Messrs. Frith and Rodgers.

Royal Institution of Great Britain.

May 8, 9 p.m.—At Albemarle-street, Piccadilly. "Electric Shadows and Luminescence." By Prof. S P. Thompson.

May 12, 3 p m—"Ripples." Prof. C. V. Boys.

May 14, 3 p.m.—"Japanese Metal Working." By Mr. Gowland.

May 15, 9 p.m.—"Cable Laying in the Amazon." By Alexander Siemens.

Institution of Junior Engineers.

May 8, 8 p.m.—At the Westminster Palace Hotel. "Notes on Belgian Electrical Engineering Practice." By A. Anstruther-Thomson and G. C. Allingham.

Society of Arts.

May 11, 8 p.m.—At John-street, Adelphi. Cantor lecture. "Applied Electro-Chemistry." By James Swinburne. (The third of four lectures.)

May 12, 8 p.m.—"Wood Engraving." By W. Biscombe Gardner.

May 13, 8 p.m.—"Tunnelling by Compressed Air." By E. W. Moir, M.Inst.C.E.

Northern Society of Electrical Engineers.

May 11, 8 p.m.—At the Palatine Hotel, Manchester. "The Use and Economies of Rectifiers for Arc Lighting." By John Hesketh.

Liverpool Engineering Society.

May 16.—Visit to the Southern Extension Works of the Overhead Railway.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE 1896 JAMES FORREST LECTURE.

The lecture under the above title delivered annually at the Institution of Civil Engineers is always looked forward to with interest. The subject this year is the relation of physical experiment to engineering. In the able hands of Prof. A. B. W. Kennedy the subject has received most careful treatment, which will cause the lecture for 1896 to be regarded as the classical work on these matters. The lecture is reproduced in our columns, and we only regret that space will not permit of it being given in its entirety in one issue. The whole of the treatise is worthy of close reading, and the views expressed have our complete approval. Dr. Kennedy draws a great distinction between the experiments of the scientific investigator and those of the engineer, and points out how few men can work in both of these widely-varying pursuits. Still, either course of research is worthy of the life-work of any man. The professor's introductory remarks on the theory of evolution in engineering matters opens out a wide field for thought, and we can only hope that this subject may be more extensively dealt with by the author at some early date, as his experimental studies of the details of certain branches of engineering enable him to speak with no uncertain voice on these matters. The three classes of physical experiments detailed by Prof. Kennedy are those undertaken from the purely educational point of view, the purely physical experiment for the determination of scientific facts, and, lastly, the technical experiment. The first class, as a training, is very essential to anyone who is afterwards to undertake experiments of the other classes, as an untrained man cannot as a rule observe and record his observations with any degree of accuracy. In this respect the members of the technical Press are apt to be specially at fault, more, perhaps, owing to the sunny side of engineering usually shown to them. We have often noticed in a description of some plant the expression that "the writer has never seen an equipment more complete and satisfactory," and yet it has been known to accurate observers that certain parts were even then in a disabled state. As pointed out in the above lecture, "the ordinary mind does not naturally and at once see, and see accurately, the simplest thing that is before the eyes. One has to look, to exercise conscious mental effort, as well as merely to see, and we all of us require to be taught how to look, even in these most simple matters. And when the enforced looking has to be done at exactly a particular time, and no other, the average mind is apt to find the whole process an intolerable burden, all the more because it is inclined to despise the work as being too childishly easy for consideration at the very time when it is failing to carry it out!"

The pure physicist has a much wider field of research than the engineer, and his researches are most useful in many ways to the engineer, as providing the constants used in engineering formulæ. Yet the engineer, having a more limited field for his researches, has a greater interest in his particular field of investigation because of its limitation. Thus, Prof. Kennedy justly "resents the way in which

Digitized by Google

physical writers and speakers are occasionally inclined to instruct us how to express our ideas—for example, as to mass and weight, and sundry vital matters of that kind." He thinks "that people who have to deal with these matters as much, as often, and as thoroughly as we have, and who are on the whole reasonably competent beings, may be assumed to know how best to manage our own affairs in these respects. Mechanics are to us the breath of our nostrils, and not a mere vehicle for examination papers, and it should be remembered that the requirements of the latter case may be very different from those of what he ventures to call 'real life.'"

Again, the pure physicist carries out his observations on lines which tend to eliminate all but the effect he is investigating. His whole object is to one single end for the time being, and he so designs his apparatus as to exaggerate the special phenomena to be measured. The engineer, on the other hand, is always combated by conflicting interests. Thus, the £ with two crosses is as important in electrical matters as the £ which stands for self-induction, and in all engineering matters the cash considerations oft tend to prevent abnormally efficient work from being carried out. Again, the physicist aims at absolutely correct figures, which in the engineer's observation would be absurd. Thus, in the experiments made by the engineer the limitations as to accuracy are considered by Prof. Kennedy. It is useless to give the results of coal consumption per kilowatt-hour in the trial of a complete central-station plant in five or six significant figures, as some people delight to do, although at the same trial commercial voltmeters and ammeters are used to determine the outputs and are not checked. We entirely confirm the concluding remark in this lecture, stating the fact that the great strides made in perfecting the various engineering appliances during the last twenty years are due in a very great measure to physical experiment carefully made and carefully used as a guide to future work.

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

BY DR. ARMSTRONG, F.R.S.

(Continued from page 495.)

To explain the formation from chloracetic acid, for example, of salts on the one hand and of hydroxyacetic acid on the other, Ostwald assumes that it not only dissociates into the ions H and $CH_2Cl{\cdot}CO_2$, but also to a slight extent into Cl and $CH_2{\cdot}CO_2H_2$; his theory, in fact, forces him to assume that an electrolyte may ultimately split up in different directions. But no such difficulty arises in connection with the association theory. According to this, the manner in which change will occur depends on the nature of the substances present and the extent to which they are compatible—a compound, such as chloracetic acid, behaving as an acid when substances are present to which the acid radicle is attractive, as a chloro-derivative when substances are present which are more attracted by the chlorine, "local" circuits being established which proceed from and include one or the other part of the molecule, according to circumstances. As the changes which take place when such circuits are established will depend on the nature of the circuits, it is easy to understand the formation from chloracetic acid, on the one hand of hydroxyacetic acid, and on the other of dichloracetic acid, even supposing the chlorine to be the attracting element: the difference would depend primarily on the association with the chlorine atom either of an alkali or of chlorine—*i.e.*, on the difference in the associate. To account for the formation of dichloracetic acid on the ionic hypothesis, it is necessary to assume that chloracetic acid will ionise not merely in two ways, but also in a third—viz., into H and $CHCl{\cdot}CO_2H$. Nay, more, if the argument be extended, in order to account for the formation of chloracetyl chloride, $CH_2Cl{\cdot}COCl$, a fourth possibility must be admitted—viz., into $CH_2Cl{\cdot}CO$ and OH!*

I have dwelt thus fully on these questions, as, apart from the interest attaching to such problems, it is all important to establish the exact nature of the changes which attend the dissolution of metals and the precise character and functions of substances which act as depolarisers, our power to utilise chemical change at will as a source of energy depending on the extent to which we comprehend the inner meanings of all such changes. The function of the depolariser is far from appreciated, there being too marked a tendency to regard it merely as an agent whereby polarisation is prevented, the fact being often overlooked that it directly contributes in a very important manner to the energy of the cell, in many cases making changes possible which could not otherwise occur.

In all cases of chemical change energy is ultimately degraded, but in most cases a switchback rather than a simple inclined plane is the graphic analogue of a circuit of chemical change. Or, still better, we may liken it to a system of pipes laid up and down hill through which water is supplied to a town, in which case the function of the depolariser is comparable with that of the standpipe or accumulator at the pumping station, up and through which the water is forced in order to secure the head which is necessary to overcome the friction in the pipes and to cause water to mount the hills in the district supplied, as well as to raise it to the tops of the houses and in the fire-mains. Such hydraulic systems can only be constructed of pipes which can be fitted together, just as chemical changes can only be brought about between compatible substances. Lastly, those who enjoy a constant service have no right to assume that the supply of water is automatic. On the contrary, a complex organisation which may altogether escape notice is required to secure it. And so it may be in the case of electrolysis and chemical change.

Before concluding this section it is desirable to refer to the behaviour of electrolytes which yield a variety of products according to the conditions under which their electrolysis is effected. For example, that of sulphuric acid solutions which afford not only oxygen and hydrogen, but also persulphuric acid, hydrogen peroxide, and ozone. If action take place primarily in an electrolytic circuit in but one way, how are we to account for the formation of persulphuric acid? Its production would appear to afford evidence that the acid acts both as electrolyte and as "oxygen depolariser," which is against the conclusion previously arrived at. The difficulty disappears if it be supposed that the first products of electrolysis are hydrogen and persulphuric acid—*i.e.*, that instead of water being directly resolved into 2H and O, or the acid into H and HSO_4, or 2H and SO_4—the conventional views—the acid is couverted into 2H and $H_2S_2O_8$. Richarz some time ago advocated this view (*Zeit. physikal. Chem.*, 1889, 4, 28), and it is also in accordance with Ostwald's contention that the dissociation of dibasic acids of the form H_2R'' primarily takes place (in relatively concentrated solutions) into $H+HR''$. It may be supposed that under ordinary conditions, when the electrode surface is large, the decomposition of the persulphuric acid is determined by the tendency of the electrode to attract oxygen, whilst, if the electrode surface be small and the current density high, much persulphuric acid has the opportunity of escaping into the solution, and of remaining to a considerable extent unchanged if the acid at the electrode be more or less concentrated and favour its survival, but somewhat rapidly undergoing hydrolysis into sulphuric acid and hydrogen peroxide in weak solutions. The formation of ozone may in like manner be regarded as the outcome of oxygen depolarisation by the persulphuric acid—*i.e.*, of the interaction of oxygen on the electrode with the acid under the special conditions which attend high current density—or it may be that ozone, not oxygen, is the ordinary product, and that this in turn suffers decomposition at the electrode surface when this is large.

It is commonly assumed that we know what happens when a solution of hydrogen chloride is electrolysed—that, in fact, it is directly resolved into hydrogen and chlorine; indeed, the primary article of faith in the creed of the ionic dissociationist carries us even further, asserting, as it does, that the chloride spontaneously breaks up into hydrogen and chlorine ions, and that these, giving up their charges at the electrodes, form hydrogen and chlorine molecules. The production of chlorine may, however, be the outcome of secondary changes. Assuming that muriatic *acid* consists of hydrated molecules, let us suppose, of the composition $H_2O{\cdot}ClH$, these may yield a peroxide, $H_2O_2{\cdot}(ClH)_2$, which, in concentrated solutions, either breaks up into chlorine and water, or is so resolved under the influence of the acid, but in weak solutions undergoes hydrolysis, oxygen being evolved by the decomposition of hydrogen peroxide at

* Presidential address delivered before the Chemical Society.

* Why, it may be asked, should the atoms keep together at all, if they are thus willing to separate in so many ways?

Digitized by Google

the electrode surface. Or it may be that the chlorine is oxidised, and a chlorous compound formed from the acid, from which chlorine and water are then liberated by the action of hydrogen chloride. There is reason to think also that the electrolysis of organic acids may, in like manner, involve initially the formation of "peroxidised" products.

All those are questions which require further experimental investigation and consideration. Meanwhile, it is all important to bear in mind how little we really know of such matters. They fall into the same category as the enquiry into the constitution of acids generally, which, I venture to think, must be regarded as still open to discussion, for in scientific work, as in ordinary life, we are much subject to the influence of waves of fashion, and are even apt to be misled by the beauty of a new conception. Faraday taught that the water was decomposed on electrolysing diluted sulphuric acid, and formerly chemists believed that when a metal dissolved in an acid solution it displaced hydrogen from water, and that the oxide thus formed combined with the acid. The binary theory of electrolysis introduced by Daniell in 1839 (*Phil. Trans.*, 1839, 97), however, shook faith in this interpretation; but this theory did not gain full acceptance until after the publication of Williamson's entrancing views on the nature of salts and his discovery of chlorosulphonic acid in 1851-53, from which time onwards the old Berzelian system of representing oxy-acids and their salts was fairly generally abandoned. Yet if we now, without prejudice, calmly review the facts we cannot but admit, I think, that the verdict must still be "not proven." If we, however, in any way return towards the old view, we shall probably have to steer a middle course, and consider that water is not initially active as such, but rather what may be termed combined water. Should a view of this kind ever prevail, especially if it be admitted that in the case of muriatic acid the active substance is a hydrate, $(H_2O)_x(ClH)_y$, the insight and prescience displayed by the older workers, whose minds were untrammelled by the weight of theory, will deserve fuller recognition than is now accorded to them, and Lavoisier's choice of the name oxygen will be more absolutely justified than it has ever been admitted to be since Davy's investigation of chlorine.

The discovery of the nature of the phenomena underlying electrolysis—and therefore those underlying chemical change—may not improbably be assisted by the study of substances other than conducting solutions: and for other reasons also the study of the electrical properties of such substances appears to be of the highest importance.

Thus it is well known that whereas metals generally are relatively good conductors, non-metals oppose a very great resistance to the passage of an electric current. A question of the utmost importance to consider is whether non-metals may not be capable of opposing an infinite resistance, and whether it may not be possible to base on electrical behaviour an absolute distinction between metals and non-metals, although hitherto we have been obliged, on general chemical grounds, to conclude that no line can be drawn, and that, in fact, the metals insensibly shade off into non-metals through the metalloids such as arsenic, tellurium, etc.

As long ago as 1887, in the course of the discussions which took place within the British Association Electrolysis Committee, I drew attention to the importance of making further observations on the specific resistances of the non-metals—pointing out that as these appeared all to behave as electrolytes of very high resistance, it became a question whether this might not arise from the fact that impure substances had been studied, and adding "if sulphur, etc., are found to behave as water—that is, to increase in resistance as they more nearly attain a pure state—then I think we may fairly divide elements into two distinct classes, and define a metal as an element which conducts, and a non-metal as an element which insulates."

The behaviour of sulphur, selenium, and other well-defined non-metals, in fact, is such, that there is hope, I think, that eventually we may be able to draw such a distinction. It is true that Monckmann in 1888, in a paper communicated to the Royal Society on the specific resistance, etc., of molten sulphur, showed that this substance had a not inconsiderable conducting power; and that when objection was raised against the results on the ground that no special care had been taken to purify the sulphur, he extended his experiments, recognising the necessity of obtaining "the purest possible specimens of sulphur," but arrived at results essentially in agreement with his earlier observations. Apart, however, from the fact that the methods of purification he adopted can scarcely be regarded as calculated to afford a "pure" material, and that there is internal evidence in the paper that he was not dealing with a pure substance (it can scarcely be doubted that "pure" molten sulphur would be without action on platinum), it may be noted that only about six months intervened between the presentation of his two papers; had six years been devoted to the task, the conclusion arrived at might, perhaps, have merited confidence.

(To be continued.)

INSTITUTION OF ELECTRICAL ENGINEERS, April 30.

Dr. J. HOPKINSON (president) in the chair.

ON RAILWAY TELEGRAPHS, WITH SPECIAL REFERENCE TO RECENT IMPROVEMENTS.

BY W. LANGDON, MEMBER.

(Concluded from page 489.)

Staying.—It is no exaggeration to say that to the more perfect manner of staying the telegraph lines of the present day, and to the employment of machine-stranded staying wire, are we indebted for that greater immunity from heavy breaks-down which we enjoy at the present time. It is, in cases of snow, falling under those conditions which cause it to cling to the wires, a question of strength of pole *versus* strength of wire. Needless to say it is preferable the wires, rather than the poles, should suffer; and, as a rule, such is the status at which well-built telegraph lines of the present day have arrived. On railways there is usually more room for staying poles than is the case on roads. The greater the spread of the stay the greater its advantage. In order to be of the greatest service its attachment to the pole should be somewhat above the centre of the full complement of wires which the pole is designed to carry. It is seldom, however, one can determine the number of wires which a line shall ultimately support, and thus it is well to fix that point which may be most serviceable under any condition. The practice pursued by the author has been to fix the upper stay between the third and fourth arm, and where a second stay is required—as is frequently the case with heavily wired lines—between the eighth and ninth. Formerly the practice was to form the stay on the pole, wire by wire. A single wire was first attached to the pole and strained up tightly to

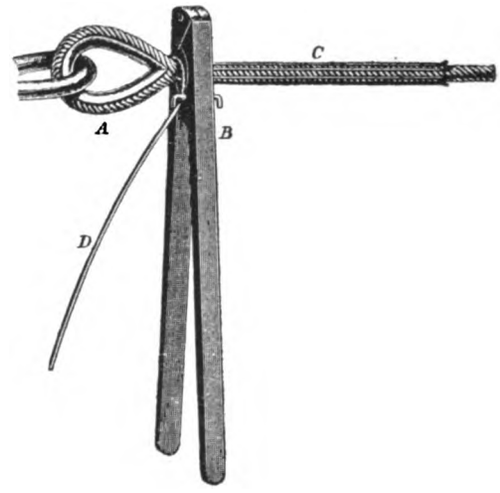

FIG. 4.

the stay-rod; then a second wire was attached and strained up, as nearly as could be judged, to the same degree of tension; and so on, till the necessary strength was attained. The objection to such stays is the absolute improbability of so arranging the several wires of which the stay is composed that each shall bear its share of the strain. As a rule the strain falls upon one wire more than another. Under great stress this wire is the first to give way. The rest follow in like manner. With machine-stranded staying wire each wire bears its own proportion. If properly stranded—*i.e.*, with a long lay—it is easily handled. Where attached to the stay-rod it should be passed around a pear-shaped eyelet. To Mr. W. H. Preece, C.B., F.R.S., past-president, we are indebted for the introduction of machine-stranded wire for this purpose. Staying wire should be of a steely character. The Midland specification provides that each No. 8 gauge wire (which is the only gauge used for stranded staying wire) shall stand a strain of 1,800lb., with a maximum stretch of 4 per cent., without breaking, and that it shall bear 12 twists in a length of 6in. without fracture and without scaling. An excellent device for binding stranded stay wire has recently been introduced by Mr. Roberts, of the Postal Telegraph Department, which enables the workman to accomplish his task well and with ease. The tool itself will be found upon the table.

The strand wire is first bent so as to form the loop around the stay thimble, A (Fig. 4), the splicing tool, B, being employed to draw it closely into the groove. The free end of the stay wire is then unstranded and the wires straightened out, as shown at C. One wire, D, is picked out for the purpose of forming the first lap of the binding. The tool is then employed to arrange the remaining wires symmetrically parallel with and around the main strand so that they may bind into it without

Digitized by Google

spoiling its circular shape. The free wire is now placed under the hook of the stay tool, which is revolved around the stay and the remainder of the wires. When the first selected wire has been used up another is chosen, and the same course followed with each until all have been evenly bound around the main stay. All stay-rods planted in soil formed of cinders or ashes should be protected by fillets of creosoted wood, or they will rapidly succumb to the electrolytical action set up by the ashes and the galvanised iron. On railways it frequently happens that the top ballast is composed entirely of refuse cinders or ashes.

Insulation.—For many years a practice has prevailed of using a minor form of insulator for short-circuits or block-signalling wires. The author raises the question whether such a degree of refinement is desirable. It is inconvenient, inasmuch as it does not admit of interchange of wires where such changes are desirable. On the Midland the practice has long been abandoned. But one class of insulator, and one gauge of iron wire—

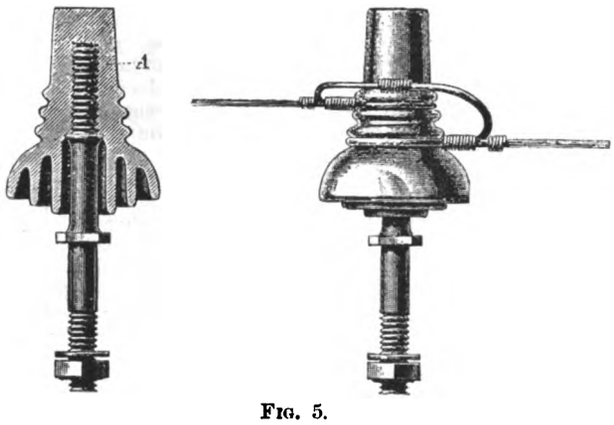

FIG. 5.

viz., No. 8—is employed. Thus, when required, through wires may be joined in with the shorter lengths, and the uniformity of the line preserved by maintaining the shorter lengths below the longer ones. Moreover, it would appear that, however important other wires may be, none can be more important than those which govern the movements of the trains. It is believed that the best insulators are those known as the "Post Office" and the "corrugated," samples of which are on the table. Samples of the form of terminal insulator and leading-in cup, employed largely by others as well as by the author, are also before the meeting. The terminal insulator is made in two sizes, the smaller kind being employed where the strain is small, as, for instance, for leading across from one side of the line to the other for signal-box and other like purposes. The larger kind is employed for terminations of line wires. The great advantage of this insulator resides, not merely in the shape of the ware, but in the extent of the bolt, A (Fig. 5), which, it will be seen, passes far beyond the corrugations at which point the line wires are attached—a provision which renders it practically impossible for a wire to fall, even when the porcelain

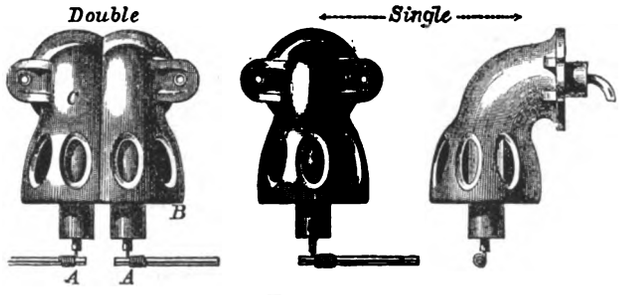

FIG. 6.

is from any cause broken. Another advantage is that these corrugations, or grooves, not only help the insulation, but make provision for the attachment of different gauges or different descriptions of wire, as, for instance, if it is desired to attach a No. 11 to a No. 8. If the No. 8 is placed in the lower groove, and the No. 11 in the upper groove, the strain on the bolt will be about equalised, and the insulator will retain its vertical position. They are equally useful for joining two descriptions of wire—say, iron and copper—the one being terminated on one ring, and the other on another, the two wires being joined by a loop. At the termination of all important wires, and, in many instances, at important signal-boxes, "leading-in" cups are employed. They are formed (Fig. 6) of a porcelain tube, A, in which the G.P. wire is threaded, the tube being contracted at B, so as to keep the wire central and free from the edges of the tube. This tube is protected by an iron hood, C, perforated, so as to admit of the rain cleansing the porcelain tube. Where round creosoted poles are employed for leading-in wires, it is necessary to carry the G.P. wires in boxing fixed between the arms. If this boxing is strongly made, it will admit of the leading-in cups being fixed to either side of it, and will thus form a very complete and durable termination.

Wire.—Considerable progress has of late years been made in the employment of copper wire. The first copper wire erected for telegraph purposes was, it is believed, that erected by Mr. A. Graves, of the North-Eastern Railway, at York, about 1877. Mr. Graves on that occasion employed No. 14 gauge (·080 S.W.G.), and shortly afterwards, in 1880, copper wire of the same gauge was erected on the Midland. The copper wire of various gauges in use on the Midland now extends to some 5,000 miles, of which 3,000 odd is maintained for the Post Office. The objection to iron wire is the shortness of its life, and—in comparison with copper—its higher electrical resistance and greater inductive capacity. Under the auspices of the Post Office a class of iron wire largely superior to that formerly in use has for some years past been obtainable. This improvement—embracing conductivity and the general construction and character of the wire—does not, however, extend to prolongation of life. In a few years, more or less, dependent very much upon the condition of the atmosphere, the galvanising is gone, rust sets in, and thereafter the strength of the wire, as also its conductivity capacity, rapidly degenerates. Covered iron wire is frequently found to be of great service in smoky localities. The best is that served with what is known as "West's compound." The wire is lapped with cotton, and

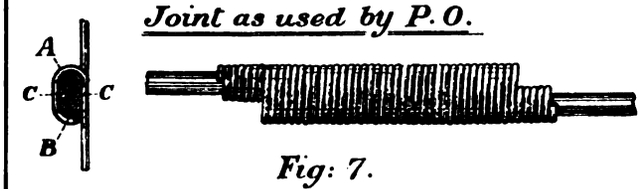

Fig: 7.

then passed through a special liquid composition, so that the cotton covering may become saturated by it. It differs from all other covering processes in that the composition hardens when exposed to the air, is unaffected by changes of temperature, and when hardened is impervious to wet. So long as the covering remains sound the wire beneath it retains its original condition, and when the covering is removed appears as fresh as when new. A sample of some of this wire which has been in use on the Midland for some years will be found on the table. The conductivity resistance of a 12½ gauge (·097) copper wire is 5·934 ω per mile; that of No. 8 (·160) gauge galvanised iron wire is 12 ω per mile. The breaking strain of the 12½ copper is 409lb.; that of No. 8 galvanised iron, 1,100lb. The cost of a mile of 12½ copper is about £4. 4s.; the cost of a mile of No. 8 galvanised iron wire, £2. 10s. The difference in price is considerable, but against this we are able to place many advantages: durability—which means less cost in renewal, a saving of certainly two out of three, which at 20s. a mile more than covers the additional cost; reduced strain, and less load on poles, which admits of their reception of a greater number of wires; and last, though not the least important, less liability to

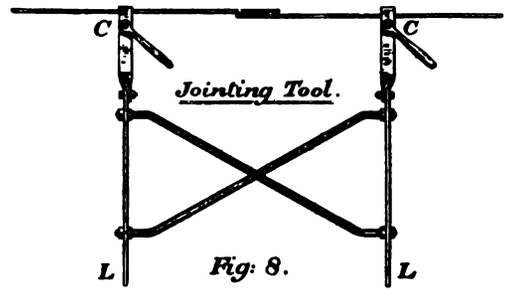

Fig: 8.

fracture. It is probable that 12½ copper, or possibly a slightly larger gauge, will entirely supersede galvanised iron wire; for, although when new the galvanised iron wire has the advantage in tensile power, it retains that power a portion of its life only, and during the latter part of its existence its tensile strength is even less than that of the 12½ copper. Its electrical resistance is, even when new, more than twice that of the copper wire. It is desirable in using 12½ gauge copper wire, where possible, to slightly reduce the length of span—to limit it to 70 yards on the curve and 75 on the straight—say 24 poles to the mile, instead of 22. In all newly constructed lines for the Midland Company's own purposes, copper wire is now used; and in the renewal of existing wires, iron is, as a rule, being replaced by copper. In the erection of either copper or iron wire, the degree of tension to which the wire is pulled up is a factor which plays an important part in its durability. Wiremen, until they are taught otherwise, have a profound contempt for the

Digitized by Google

effect of temperature upon the material they are using. On a hot summer day, or a bleak winter morning, they will pull the wire up to the same degree of tension. The consequence is that the wire erected under its maximum expansion in the hot noontide is either broken or stretched under the influence of a lower temperature. The dip, or the stress, imparted to a wire must always be governed by the temperature, for which purpose a thermometer, placed in a position analogous to the wire, must be used. Where wires are run on the parallel system, if the top wire is erected to the required degree of tension, the eye of the wireman can by it readily regulate other wires in the same span. To impart to this wire the proper degree of tension its stress must be determined by its "dip," or by what is known as an indicating tension-ratchel, the latter by preference. Where wires are erected on the "revolving" system, it is impossible to avoid the use of the tension-ratchel if the wires are to enjoy a uniform degree of tension. To Mr. W. H. Preece, C.B.,

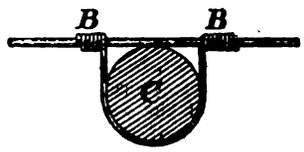

Fig: 9.

F.R.S., we are indebted for much careful investigation of this important question, and by his courtesy I am enabled to add, in the appendix to this paper, tabulated statements adopted by the Post Office showing the stress at which both copper and iron wires should be erected at various temperatures.

Jointing.—The "Britannia" joint still holds its own, whether for iron or copper wire, but the ends (or "tails"), which for years have been left bent up, are now cut clean off, it being evidently better for a joint to *draw* than to form an intermittent fault. The Post Office, with regard to copper wire of large gauge, before soldering, fill the interstices between the two wires, A, B (Fig. 7), and the binding by two pieces of smaller gauge wire, C. The object is to facilitate the soldering of the joint, and so prevent overheating the copper. The joint when completed is wiped clean, and allowed to cool. It should not be overheated, and it should not be chilled. Where joints are made in this manner, a jointing frame becomes necessary. This consists merely of a couple of clips, C, C (Fig. 8), in which the ends of the wire are held. It can with convenience be fixed by the legs, L, L, to the wiring barrow, or the legs may be thrust into the ground; and here, perhaps, although a minor matter, it may not be out of place to call attention to an improved "wiring barrow" which has recently been brought into use. These barrows are made with a frame similar to that of a garden barrow, but longer. The drum for the reception

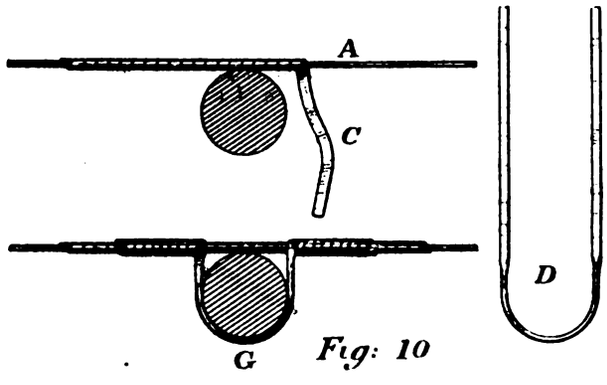

Fig: 10

of the wire is made of sheet iron, and works vertically, instead of horizontally as hitherto. Ordinarily the barrow is wheeled along the sides of the line by one man, as on a public road; but where it cannot be wheeled, two portable arms, provided for the purpose, are placed in position, and the barrow is then carried in the usual manner by two men. The arrangement will be understood by reference to the photographs on the table.

Binding.—For many years the author has abandoned the use of No. 16 galvanised iron wire for binding, and has employed in its place a specially made No. 11 galvanised iron wire. It is necessary this class of binding wire should be more ductile than the ordinary conductivity No. 11 galvanised iron wire, and that it should be capable of being lapped around a No. 8 wire without scaling. If it scales it will rust, and the oxide will be carried by the rain down the outside of the insulator cup, to which it will adhere to such an extent as may in damp weather materially affect the insulation of the wire. In Fig. 9, C represents a cross-section of an insulator at the point at which the binding wire is attached. The binder is merely lapped some five times around the line wire, as shown at B. It will be found that this form of binder will prevent a broken wire from running back quite as well as any form of binding with No. 16 gauge wire. Its advantages are great durability, absence from stretch under influence of gales, less cost in construction and maintenance, and greater freedom from chafing, the line wire being much more firmly held. The practice thus pursued by the author has in a modified form been adopted by the Post Office with respect to copper wire. That portion of the line wire, A (Fig. 10), which rests against the insulator, B, as well as the portion which is to be lapped by the binder, is first overlaid by a copper tape, C, a piece of copper wire rolled out flat. The binder, D, is formed of a large gauge wire which has its two ends flattened so as to be readily laid around the taped portion of the line wire. Both the tape and the binder are first laid on by hand, the copper strip being exceedingly ductile, and finally tightened by the aid of a suitable pair of pliers, the complete binding being as shown by G

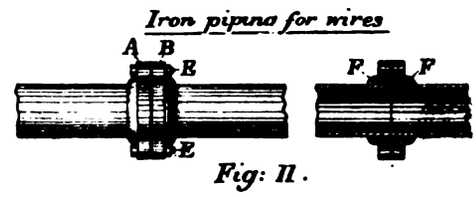

Fig: 11.

(Fig. 10). Samples of these binders and tapes, as well as of the complete form of binding, are on the table. The author is of opinion that wherever a sufficiently ductile wire can be obtained for the purpose it is better to employ a binder of a gauge equal, or nearly so, to that of the line wire. The Post Office, under the direction of the engineer-in-chief, have recently issued tables of sizes, weights of tapes, and binders for the different gauges of copper wire, which, by Mr. Preece's permission, I have the privilege to append to this paper.

Guttapercha and Covered-Wire Work.—It is believed there is very little to record in the matter of guttapercha-covered wire. In making it a practice to use ozokerite taped wire in all instances for underground work, or for wooden casing, it is probable the author is merely following the practice of others. The taping adds very little to its cost and very largely to its life. The number of wires which are now required for signalling purposes—the fact that, as a rule, the "leading-in" pole is placed in the rear of the signal-box, while the instruments are invariably arranged over the signal lever frame in the front of the box—leads to a large consumption of guttapercha-covered wire, and renders it all the more necessary that every precaution should be adopted to preserve the life of the insulation. To this end all G.P. wires should be boxed in, and the boxing (which should be grooved from the solid), when carried underneath the floor of the signal-box, should be inverted, so that any moisture from the washing of the floor of the signal-box may not penetrate the boxing and impair the percha. The author has for some years employed wire covered with indiarubber, plaited cotton, and compound, for signal posts. It withstands the heat much better than G.P.; the conducting wire is less liable to become decentralised; and he has good reason to believe that it will prove very durable. Although instances have arisen where armoured cables composed of from

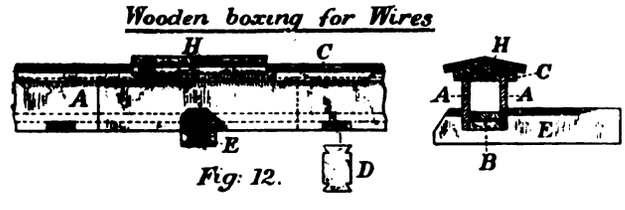

Fig: 12.

three to ten conducting wires have been employed for telegraph and signal purposes, it cannot be said such are in general use. In station yards, where the wires are generally laid underground, and in other equally crowded places, armoured cables for odd lengths will probably be found not only useful, but, in order to avoid disturbing the body of through wires, a necessity. Such cables are extremely useful for crossing the line of railway for repeater or similar purposes, where, unless the wires are carried underground, a large alteration is necessary in the poles in order to carry them overhead. In laying down some underground work at Leicester and Nottingham, a simple form of cast-iron piping, which, having an indiarubber joint, is very quickly placed in position, has been used. It is inexpensive and readily handled. An illustration of the joint will be found in Fig. 11. A B are clamps which slide over the pipe, D, which is merely a straight tube. A B are recessed at A' B' so as to receive the small piece of tubing, C, together with an indiarubber washer, at either end. The pipes, D, are laid out so as to meet at C. A and B, as well as C, are then slipped on, the tube, C, is brought into its proper

Digitized by Google

position, and A and B are then closed up and tightened by the bolts, E. The indiarubber washers afford a firm grip, so that the pipes, D, are not readily drawn apart. The arrangement is better suited for level ground than for heavy slopes. Fig. 12 represents a form of wooden boxing for tunnels and wall work. It is the production of my inspector carpenter, Hobday, and is set together and maintained in position without the aid of a nail or screw. It is formed of four pieces of wood. The side pieces, A A, are grooved to accept the bottom board, B; the top, C, is grooved to accept the side pieces; the two sides are held together by tie-pieces, D, inserted at intervals of 3ft. Instead of iron supports, wood blocks, cut from flawed or otherwise unsatisfactory oak arms, are shaped as shown by E to receive the boxing. These supports are fixed in the masonry by wood wedges or cement 6ft. apart. A piece of wire passed around the support and the boxing holds the entire structure safely in position. No two pieces of wood from which the boxing is composed terminate at the same point, with the exception of the lid. At the junction of these pieces a wooden capping, H, is employed to cover the seam.

Instruments.—In telegraph message instruments the vertical handle "single needle" remains that generally used in Great Britain. For some years it has been the practice on the Midland to employ, at the transmitting or terminal station of all busy single-needle circuits, a "Bright's Bell" in place of the single needle—an arrangement which will be found to aid dispatch and lighten the labour of the clerk. The Bright's Bell is also largely used by the Great Northern between telegraph offices. The Lancashire and Yorkshire and the Great Eastern employ it on single-needle circuits in a similar manner to the Midland. Although the "sounder" is very generally employed for railway message work in Ireland, it cannot be said to have taken root on English railways. For direct and long circuits it is occasionally used, but it is believed not to any great extent.

Fig: 13.

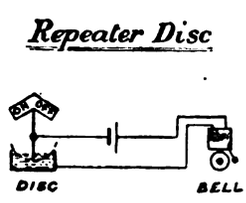

Fig: 14.

For "quadruplex" working the demand does not appear to have been very urgent. It is employed by Mr. Hollins on the Great Eastern, between London and Harwich. "Duplex" working is employed on the Great Eastern, Caledonian, London and South-Western, and London and Brighton, and on the Midland. On the Midland a duplex circuit between Derby and London also provides for a phonopore communication. The phonopore is employed to a very limited extent on the Midland, Great Western, Great Eastern, Brighton, and North British lines. Telephones, as was to be anticipated, are now very generally employed for *viâ voce* communications between signal-boxes, and at busy centres between the administrative offices. That their employment largely aids the disposal of traffic there can be no question. At many points, and under exceptional conditions of weather, they are invaluable. On the Continent, as well as at home, serious rumours have from time to time, arisen with respect to the dissemination of disease by means of these instruments. It has been contended that a person suffering from throat or other internal affection, on speaking into a transmitter, may leave in the interstices of the instrument germs of the disease, which may be inhaled by others using the same instrument. Fig. 13 represents a transmitter which has been designed with a view to obviate any such evil effect. The ordinary mouthpiece is removed, and in its place the entire face of the instrument is covered by a diaphragm, A, made of wood or metal—the former by preference—which encloses an air space, C, between it and the ordinary or electrical diaphragm, B. On speaking in the neighbourhood of the outer diaphragm its vibrations are transmitted by the pressure of the enclosed air to the electrical diaphragm. Speech is marvellously clear, and only when used for long-distance telephony—as between London and Glasgow—is any diminution in the sound noticed, and then only in a very slight degree.

Block-Signalling Instruments.—The practice of arranging the block-signalling instruments apart from the signal frame has with most companies been abandoned. As a rule, all block apparatus is now fixed on a shelf immediately over the signal frame so that they may be readily manipulated by the signalman, and their indications remain present to his view. With the exception of the introduction of Tyer's tablet block, and Messrs. Webb and Thompson's electric staft for working single lines, there is little of novelty in block instruments to record. Interlocking the electric with the mechanical signals has made but little progress. The mileage of railway lines in Great Britain (see Table A) worked under the absolute block is 26,398. A very small fraction of this has the electric signals interlocked with the mechanical signals. It appears almost marvellous that the enormous traffic which now passes over our railways should be conducted with so few casualties under an arrangement which entails a perfectly independent action for both the electric and the mechanical signals. The former are provided for the regulation of the traffic between signal-post and signal-post, but where they are not interlocked with the mechanical signals, which are those which actually guide the engine-driver, they merely indicate to the signalman how he is to work his signals; they in no way control them. That so few casualties arise testifies in the highest degree to the care and watchfulness

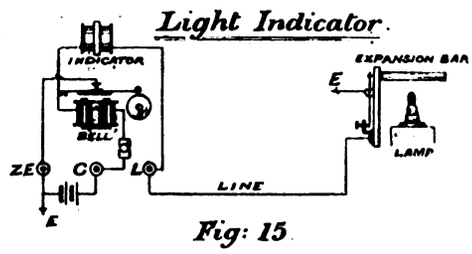

Fig: 15.

exercised by the signalmen to whom falls the duty of working the traffic under such conditions. The subject is one which may well lay claim to further consideration at the hands of some member of this Institution. In the meanwhile, it may be desirable to point out that the interlocking which has, so far, been employed is still wanting in finality. As now used it is the first vehicle which releases the lock. Needless to say, it should be the last. Electric "signal repeaters" and "light indicators" have become indispensable adjuncts. On the Midland there are no less than 3,000 of the former and some 800 of the latter in use, and with many other companies the number is no doubt as large. Another useful adjunct is that termed the "repeater disc," employed to indicate the movement of the lever of "slotted" signals. It differs from the signal repeater in that the indicator when passing from the "on" to the "off" indication directs the signalman's attention to the alteration by ringing a bell (Fig. 14). "Light indicators" should be so constructed that they may indicate any failure in the light by a continuous ringing of the bell. The entails the maintenance of the "Light in" signal by permanent current. Two No. 1 Leclanché work the instrument perfectly well. Fig. 15 is a diagram of the connections. Fig. 16 is a diagram of the signal repeater arrangement, the batteries being placed at the signal-post. The "on" contact, B, is fixed, and the contact which the tongue-piece, A, makes with it is only

sufficient to a movement of 2deg. The contact, C, is adjustable. Samples are on the table.

Batteries.—To the bichromate and Leclanché battery the author ascribes the palm of merit for a good and useful battery for railway purposes. For hard and constant work the former is unsurpassed. For occasional purposes and for constant action, under certain limitations, the Leclanché commands attention. The old form of Daniell (sulphate) of copper battery, it is assumed, no longer finds a profitable field in railway telegraph work. The Leclanché-Barbier cell is the latest development of the liquid Leclanché type of battery. It differs from the preceding types in the form of the positive element, together with other mechanical details. The positive element consists of a hollow cylindrical agglomerate of carbon and peroxide of manganese, around the upper part of which is cast a metal ring, caused to fit the neck of the jar, between which and the metal ring an indiarubber washer is inserted. The centre of the cylinder is covered by a wooden block, which serves to support the zinc and to close the jar. There is thus little possibility of evaporation; the cell is practically hermetically closed, and is in every way satisfactory.

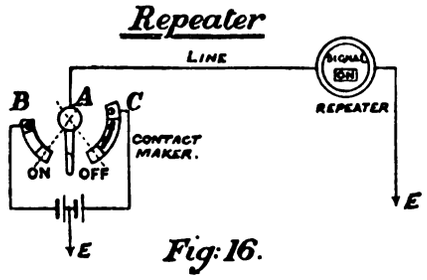

Fig. 16.

The most recent innovation in batteries is the so-called "dry cell," but of them the author cannot profess to any lengthened experience. In their early days they were frequently disappointing and unreliable. Much of that has now been remedied; yet it is doubtful if their employment on railways would be economical, for it would still be necessary to retain linemen and battery men, or assistant linemen, to attend to failures of instruments, etc., when such arose. General freedom from such failures would in no way modify this demand for the presence of the lineman. Failure at some time would be certain to arise. Whenever it did, the lineman must be there promptly to attend to it, or the traffic would necessarily suffer. I feel that, in submitting to your consideration so lengthy a paper, I have largely encroached upon your time and patience. It has, however, been impossible for me to deal with the subject in less space, and equally impossible to divide it into two parts. I believe that you will, under these circumstances, generously accord me your kind indulgence. As it is, I fear I may still have omitted some points of interest; and that, possibly, a want of knowledge of that which has been, or is being, done by others may even now render my treatment of the subject incomplete. Where such is the case, I must trust to my *confrères* to supply any such deficiency in the discussion which the paper may elicit.

APPENDIX.—Post Office Tables for Stresses to be Observed in Erecting Iron Wires at Various Temperatures.

Discussion.

On the conclusion of his paper **Mr. Langdon** remarked that he had received a letter from Mr. Graves, of the North-Eastern Railway, who wished to make a correction. The first copper wire he

Digitized by Google

erected was a short length at Gateshead in July, 1871. He (Mr. Langdon) had also received a letter from Mr. Preece on the same subject. Mr. A. Graves was not the first to erect copper wire, because all the very early lines erected in England were of copper—the Paddington and Slough line, for example. In more recent times the great start in the use of copper was when he (Mr. Preece) induced Mr. Patey to put up a copper wire between London and Newcastle. The Post Office also introduced copper wire for the telephonic service.

The reading of the paper was not concluded till past nine, and the **President,** before the discussion was opened, remarked that as they had only two more meetings, and papers for each of them, it was absolutely necessary to furnish the discussion of Mr. Langdon's paper that evening. Gentlemen who had written remarks would hand them in to the secretary for publication.

Mr. Wyles, who opened the discussion, remarked that, so far as concerned the progress of electrical interlocking, the congested traffic out of London, at all events so far as affects the railways on the southern side, was completely interlocked. He might mention the work done on the South-Western, at Cannon-street Station, on the South-Eastern Railway, and on the London and Brighton and also on the Great Eastern lines. On his own line (the London and South-Western) they had a good many cases in which the signals were thrown to danger electrically, and complete electric interlocking was fitted between Waterloo and Esher on the main line, and as far as Twickenham on the Windsor branch, and the system was being extended. The whole of the Chatham and Dover Railway and the District was also electrically interlocked by the Sykes system. Besides this, he might mention that he had also working on single lines electric interlocking, whereby the starting signal could not be lowered unless the tablet was previously drawn. This system was patented by Mr. W. R Sykes, and worked out in conjunction with the speaker.

Mr. C. Goldstone said that, in reference to what had been said in the paper as to duplex working, he thought that South-Western must be a slip for North-Western. They had not got it on their line, but on the South-Western he might say that they had something like 150 miles of electrical interlocking, and he expected by the end of the year about a third of the line would be electrically interlocked—certainly all the busy portions would. At no period of his experience of block signalling had there been greater activity than at present, especially in the direction of interlocking, which was making great progress.

Mr. Spagnoletti took exception to the system of poles in Figs. 1 and 2. If one of the poles sunk, there would be a hinge action on the other. The cross-pieces would stop that and the cross-arms to a certain extent, but it would cause a heavy strain on them. His practice was to put flat pieces at the bottom of the poles, which gave a firm foundation. With reference to staying, he had found that the heads of the bolts pulled through when the stay blocks got rotten. To obviate that he had introduced a cast-iron plate. He had not done much with iron arms, so could not speak of them; nor had he always earth-wired the arms. Stays were very important in case of snowstorms. He had had as much as 40 miles of posts down from snow. The difficulty was when the snow adhered to the wires and increased on them until they grew together. Then the wires broke on one side, and down went the pole from the pull on the other. He therefore had stayed the poles on both sides. He could not see why in open country iron wire should not be used. Mr. Langdon seemed much to prefer copper. As to iron not lasting in country wires, with a pure atmosphere he found that they simply did not know the life of them. They had had some up over 35 years. If they looked at the list of instructions and cautions issued by the manufacturers to be observed in putting up copper wires, it would be almost enough to frighten them. The terminal insulator shown was a good form, but the strain was not equalised as it was in the shackle, and it might therefore pull over. There was no advantage over the shackle in case of the earthenware getting broken, as the wire was held by the metal in both cases. Leading-in cups were excellent things, but they were not new. Mr. Latimer Clark had introduced them many years ago. As to the life of wires, it all depended where they were fixed. In some parts of South Wales, for instance, it was very short—not more than 3½ years. He had found that an excellent coating for wires was made by heating them and dipping them in boiled tar, and he referred to the experience of wires between Wolverhampton and Birmingham (a bad district) which had been treated in this way. The worst of all coverings was that they were liable to be damaged in putting up. The grip of the vice would do this, so that the wire had to be painted afterwards at places so damaged. As to electrical interlocking, it had been adopted on the Metropolitan Railway, and also for protecting trains when on their wrong lines and in crossing over. Iron tubing he did not like for crossing work, as he found that workmen were apt to break the pipe with their picks. It was better to use wood, in which the pick stuck fast, and made the workman see he was going where he should not. With reference to the telephone, using the phonopore there was no difficulty in holding a conversation and working the telegraph wire simultaneously.

Mr. C. Bright asked the author of the paper why it was the custom to use guttapercha instead of indiarubber as a covering for wire, and what was the advantage of keeping the former dry.

Mr. R. von Fischer Treuenfeld was pleased to hear that at least one branch of telegraphy—he referred to interlocking—was still wanting in finality. It had been stated by some that the sphere of telegraphy had been worked out. On the contrary, he believed that there was still plenty of room for intelligence and skill in its development. On the subject of iron telegraph poles, these had been much employed in the Colonies. But iron telegraph poles of certain dimensions did not now seem to be able to stand the strain that they did 25 years ago. The makers might, perhaps, be able to explain that. Moreover, they had now to carry more wires than formerly. Most poles were made with a wrought-iron top and a cast-iron base, and it was at the joint that the weak point occurred. Mr. Siemens, to obviate this, had designed a pole in which the wrought-iron top was carried down into the cast-iron base. As to copper wire, he (Mr. von F. Treuenfeld) was well aware of its advantages. Its smaller capacity, and consequently greater speed, might amount to an advantage of 25 per cent. But there was another side to the shield which was not so bright, and that was the very poor breaking strain of copper wire In case of snow and wind, iron would have a considerable reserve of strength remaining when the breaking point of copper wire had been already exceeded. Further remarks he would hand in for publication.

Mr. Langdon replied briefly to the various speakers. It was unfortunate that the meeting of the Institution clashed with the date fixed for the committees of many of the railway boards, and consequently several gentlemen connected with the railways were unable to be present. As to what Mr. Wyles had said, interlocking was no doubt making progress, particularly on the South-Western and Great Eastern Railways, but he thought it a matter of regret that the companies in undertaking it had not dealt with it in a final manner. At present a train entering a section puts on the block signals, which control the section; but if the train happens to be, divided, the first vehicle which passes over the point of redress enables the signalman to clear the line. The system was not a perfect or final one. The only plan was to make the release of the signals dependent on something attached to the last vehicle. With reference to what Mr. Goldstone had said to duplex working on the London and South-Western, he would look into the mistake and correct it. Mr. Spagnoletti had taken exception to the H poles. He had probably overlooked the diagonal block that was provided specially to prevent the scissors action that Mr. Spagnoletti feared would occur. Of course, with the double pole in the second figure there was nothing to prevent the sinking of one pole, and that was why he had enforced the necessity of letting the second pole stand for some time before arming it. After all, the proof of the pudding was in the eating, and he had had some hundred miles of poles on this plan without the difficulty occurring. He thought the bottoms must be very rotten if the stay bolts pulled through. If creosoted, they would not rot. Lateral staying had not been mentioned in the paper, but he had used it for many years. It was done at every tenth pole whenever the wires on the poles exceeded 20. He must congratulate Mr. Spagnoletti on having a district where wires lasted 35 years. The difficulties mentioned in erecting copper wire he had not found arise in practice As to the question of shackles or terminal insulators, the shackle no doubt took the strain better, but it was not nearly so good an insulator. Referring to the tarring of wires, he imagined the preservative value of the tar lay in the oil it contained. When this evaporated, the sediment that was left would not give much protection. He had used the phonopore to a limited extent, and if Mr. Spagnoletti could arrange to dispense with the induction they got from it, it would be an excellent instrument. In reply to Mr. Bright, he thought indiarubber became somewhat plastic on exposure to the air. If the guttapercha could be always kept in water it would be all right, but it could not, and when it became porous the access of water destroyed the insulation. Iron poles, if large enough to give the strength required, were too expensive. In reference to what Mr. von F. Treuenfeld had said as to the behaviour of copper and iron wire in case of snow, curious as it might seem, experience had shown that there was little difference between them.

The **President,** in conveying a vote of thanks to Mr. Langdon for his paper, said it had long been somewhat of an opprobrium to the Institution that they had had no papers from railway telegraph engineers. Mr. Langdon, with his excellent paper, had been instrumental in removing that opprobrium, and had done so under very considerable difficulty owing to ill-health.

The next meeting is on May 14.

STEAM SUPERHEATING.

It will be remembered that Mr. Patchell's paper "Notes on Steam Superheating" was the last one read at the meeting of the Institution of Mechanical Engineers on January 31, and the discussion on it was adjourned. This was resumed at the meeting on the 29th ult.

At the outset, **Mr. Patchell** remarked that a certain form of superheater he had alluded to as that of Messrs. Hick, Hargreaves, and Co. was really the work of Messrs. Musgrave, of Bolton. He might also say that the fan draught used at the Maiden-lane station was not greater than that of many factory chimneys. As to his not having given any opinions in his paper, he had understood that it was facts that were wanted rather than opinions.

After a description of an experimental engine by **Mr. E. Perrett,** **Prof. Unwin** remarked that as for the question of facts or opinions, there were any amount of the former on record. What was now wanted was an adequate theory. Although the vast mass of experiments made in England and on the Continent had shown that superheating was economical, the system had not been generally used because engineers had not understood the principle of it. They might use steam in three ways—that is, they might use ordinary boiler steam, which was

Digitized by Google

always wet; or moderately superheated steam, which was wet in the cylinder; or, again, highly superheated steam. This latter was, so far as he knew, only used by Mr. Schmidt in Germany. With moderate superheating, say 120deg., all the additional heat was used to warm the cylinder, and might be taken in place of jacket heat. Although what had been said about Trevithick's report of 1828 might be true enough, the practical value of the discovery of the use of superheated steam should be attributed to Hirn in 1855. The great defect in Mr. Patchell's paper was that it mixed up engine and boiler economies. Nor had he always given sufficient information to show whether the advantages claimed were really due to superheating. In all boilers the largest waste was the chimney waste. It might fall to 20 per cent., but was always the most considerable. Details as to this were wanting, but it appeared that in two cases compared the chimney waste was not the same If the McPhail and Simpson superheater was really a superheater, it was so rather by accident than by design. Of the trials quoted only those of Prof. Kennedy were at all complete, and in these the superheat at the engine was only 7deg. There was apparently a boiler gain of as much as 1lb. of water evaporated per pound of coal, but from the table it appeared that the temperature of the gases on leaving the boiler was 309deg. F. without the superheater and 376deg. when the superheater was used. Consequently the boiler could not have been working in the same way on each occasion, and he suspected that the air supply was not the same. In two or three other trials mentioned there was no means of ascertaining the ratio between the heating surface in the boiler and the superheating surface. His opinion was that the apparatus of Hirn, as used in Alsace, was the one that would come into use. If the superheaters were properly designed and placed, there was no necessity for a special device to regulate the temperature. The up take of the funnel was not the right place. In most cases a properly-designed superheater would give 15 to 20 per cent. gain.

Mr. Phillips mentioned that he saw a superheater in a steamship in 1851, though it was not used. The system was given up about 1878. The credit of introducing superheating belonged to an American—Wetherhed.

Mr. Bryan Donkin agreed that regulation of the degree of superheating was not important. The reason superheated steam was more economical than saturated steam was because cylinder condensation was reduced. The locomotive engineer had not tried superheating, and the marine engineer seemed only to remember the failures of years ago, which were really due to bad material and unsuitable lubricants. A good commercial thermometer was wanted to ascertain the temperature of the steam.

Mr. Burstall described some thermometers designed for Prof. Kennedy at the Edinburgh electric light station. With mercury thermometers errors of from 30 to 50 per cent. occurred. The thermometer he referred to consisted of two coils of fine platinum wire wound on mica strips, and the temperature was obtained from the resistance.

The discussion had to be adjourned to May 1, when a further contribution to it was made by **Mr. Geipel.** That gentleman did not think that superheating should be employed indiscriminately—at any rate, to such a high limit as had been mentioned for all purposes—without first weighing thoroughly the advantages against the disadvantages. It was generally acknowledged that superheated steam had materially less effect on the economy of high than of low speed engines; in fact, Cotterill went so far as to state that the initial condensation in a cylinder varied inversely as the square root of the speed of the engine, which showed how important was the bearing of speed on the advisability of superheating. Mr. Geipel thought tests given by Mr. Patchell went to prove this, for although, unfortunately, in none of the tables did the speed of the engine appear, yet from the description it seemed that they were, with one exception, slow-speed engines, that exception being the test made by himself using the Willans engines, which showed a much less saving. With slow-running engines, especially those which have Corliss or other automatic cut-off gear, the economy due to superheating was by no means overstated by the author. Superheating had, broadly speaking, less beneficial effect in multiple expansion engines than in engines where the whole of the expansion took place in one cylinder—at any rate where the multiple expansion reduces, as it ought to do, the range of temperature. Another point was the increase in the loss by radiation and conduction in the steam-pipes. The speaker had pointed out in the discussion on Mr. Burstall's recent paper on the electric lighting of Edinburgh, that with saturated steam at 150lb. of pressure this loss was as much as half a ton of coal per annum for every square foot of pipe uncovered which is in use during the whole year; or, if lagged, one-third of this amount. Thus for a pipe surface of 1,000 square feet, which was certainly not much for a central station, the loss would amount to, say, 250 tons of coal per annum. Now, if the steam were superheated to such an extent as that mentioned by some of the speakers, this loss would be nearly double. He (Mr. Geipel) would be interested to know if Prof. Unwin, in estimating the saving of coal by superheating at 15 to 20 per cent., included any deduction for this important source of loss. The speaker quite agreed with all Prof. Unwin had said as to the McPhail and Simpson superheater, and that the plan of first superheating the steam, and then taking away the superheat by again passing it through the boiler, was but a makeshift arrangement. Mr. Patchell referred to the great increase in the capacity of his own boiler since adopting this superheater, but before its adoption, on his own showing, the boiler was doing far less than its rated capacity, and he thought that the better boiler efficiency was at least partly attributable to the use of the thicker fire.

ST. PANCRAS VESTRY.

The following is a report of Mr. Albert E. Pycraft, chief clerk of the electricity and public lighting department, on the working of the Regent's Park station installation for the year ending December 31, 1895, together with an abstract of the accounts:

Of the total amount of loans received—viz., £99,700—the sum of £5,616. 1s. 8d has been repaid A further loan of £10,000 has been applied for, but is not yet received. The total capital expenditure on account of the Regent's Park station amounts to £113,889. 2s. 1d., being an increase on last year's account of £4,522. 18s. 4d, which is mainly for extensions of mains, services to consumers' premises, meters, and switches, and an application for a loan for this amount is required to adjust the account. In accordance with the resolution of the Vestry of April 17, 1895, the item £554 4s. 7d. for preliminary expenses appearing in last year's accounts has been written off and charged to the net revenue account. The total revenue for the year amounts to £18,921 17s. 5d., which is a net increase over last year of £1,990. 0s. 10d., but inasmuch as the charge for public lighting for the year shows a reduction of £857. 7s. 4d., the actual increase from private consumers amounts to £2,847. 8s. 2d., or nearly 23 per cent. increase. The total generation expenses amount to £6,737. 14s. 5d., an increase over last year of £561. 4s. 6d., the larger portion of which is for coal. The distribution expenses show an increase of £1,623. 13s. 11d., the large increase under this head being chiefly attributable to the necessity of replacing the whole of the insulators and bearers in the manholes, as a consequence of the explosions in culverts that occurred early in the year. Nearly £600 has been paid to contractors for this work, besides a sum of £300 for extra staff employed in cleaning the incrustation off the old insulators, and other work during the time the new insulators were being put in—a precaution which was absolutely essential owing to the nature of the incrustation and the liability of further explosions should any accumulation of gas be present in the manholes. After providing for the whole of the foregoing expenses a profit of £6,575. 15s. 4d. on the year's trading has been made (equivalent to nearly 6 per cent. on the capital expenditure) to meet the repayments and interest on loans, etc., which absorb £5,640. 10s. 9d., leaving a net profit on the year's working of £935. 4s. 7d. This sum added to the balance on last year's accounts of £1,768. 6s. 7d., less the sum of £554. 4s. 7d., written off for preliminary expenses, leaves a net balance to be carried forward of £2,149. 6s. 7d. The following table shows the yearly progress since the commencement of the electricity undertaking:

Year ending Dec.	No. of consumers.	Current sold to private consumers. 3d. per unit. £ s. d.	Current sold to private consumers. 6d. per unit. £ s. d.	Lamps, etc., applied for. Incandescent. 16 c.p.	Arc.	Motors.

The number of public lamps is 97, and the total maximum supply demanded was 11,240 amperes low tension and 80 amperes high tension.

LEGAL INTELLIGENCE.

ELECTRIC CONSTRUCTION CORPORATION v. SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

The first portion of the hearing of this action, before Mr. Justice Romer, in the Chancery Division of the High Court of Justice, was given in our last week's issue. It was resumed on Friday last, when the evidence for the defence having been closed, Mr. Eve, Q.C., decided not to call rebutting evidence.

Sir Frank Lockwood, Q.C., said the two men, Ebbsmith and Wain, were admittedly coupled together for the purpose of defrauding the South Staffordshire Company, and that being so the whole thing must be looked at with suspicion. It seemed to him a most extraordinary thing that any company could have been found to have accepted a contract such as this one.

Mr. Justice Romer said he should like to ask what Mr. Wain's object could have been in entering into a contract which he must have known would mean bankruptcy to the company.

Sir Frank Lockwood pointed out that at this time—1891 and 1892—Mr. Wain was absolutely at the mercy of Mr. Ebbsmith.

Mr. Justice Romer said he should doubt whether Mr. Wain was so absolutely at the mercy of Mr. Ebbsmith as to do an injury to a company out of which he was to get no benefit for himself.

Sir F. Lockwood said that in this particular case they had conduct that was absolutely inexplicable otherwise than by accepting the explanations he gave. What straightforward, honest object could there have been in concealing from the company what the actual contract was, and in packing the meeting with bogus shares for the purpose of carrying resolutions which should enable them to carry out this contract. In conclusion, he submitted they had here a contract impossible of performance. One was bound to ask oneself how it was those responsible so ill advised the company, whose destinies they should have protected. The answer was that they had not the interests of this company at heart, that they were in the hands of a man who was willing to betray, and had betrayed, the company, and his co-negotiator was his criminal associate. That being so, had they far to go to answer the question which should be asked in this case—viz., would it have been possible for such a contract to have been entered into by the South Staffordshire Company unless that company had been betrayed? The answer to this was, no; but for this betrayal the contract could not have existed.

Mr. Eve, in reply, said the real point, and practically the only one, was that the contract was brought about by a claim of fraud, and was so tainted with fraud that it could not stand. He submitted that the evidence did not support any such contention, for up to the end of 1893 there was no suspicion that the men with whom the company were dealing were notperfectly honest, and they were at the very head of their profession, and it was not until just before the trial of these men in this year that the details of the frauds were discovered. It was said that the terms of the purchase were onerous, but even if it would have been better to obtain new engines than to have electric traction, that was a long way from fraud. Mr. Eve pointed out that the defendant company had obtained powers to provide electricity, and having that power they set to work to find a company to supply the motive power, and when the plaintiff company entered into the contract they knew the company could not purchase for cash, and it was under those circumstances that the contract was made both a working and a financial one. He submitted that, taking everything into consideration, it was not a case in which they would impute fraud. If that was disposed of, then the question whether it was an onerous contract was not before the Court. He submitted that the charges of fraud had not been proved. The onus of proof rested upon the defendants in this case. He asked, therefore, for a declaration that the contract was binding on the defendant company, that an account be directed on that footing, and that the counterclaim be dismissed with costs.

His **Lordship** reserved judgment.

COMPANIES' MEETINGS AND REPORTS.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.

The report of this Company for the half-year ending December 31 states that the total earnings amounted to £80 315, as against £82,815, showing a decrease of £2,500 compared with the corresponding period of 1894. The working expenses were £38,122, as against £36,404, an increase of £1,718. Including £5,803 brought forward, and the dividend received upon the shares held in the "Platino" Company, the balance to the credit of the revenue account is £52,614, from which has been deducted £11,148 for debenture interest and £7,952 for the debenture redemption fund, leaving £33,514, of which £3,000 had been placed to the reserve fund. The directors recommend the payment of 5s. 3d. per share, free of income tax, on the ordinary shares, making, with the dividend paid in November, £3 per cent. for the year, the same as paid for 1894, leaving a balance of £4,953 to be carried forward. In the case of shares which have been divided into "preferred" and "deferred," the 5s. 3d. per share now recommended will be payable—3s. 9d. to the "preferred" shareholders, making up the full dividend of £5 per cent. on these shares for 1895, and 1s. 6d. per share to the "deferred" shareholders. It is stated that there is no change in the position of affairs between the Government of Brazil and the Company as to the purchase of the cables. The shareholders' meeting will take place on May 14.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY, LIMITED.

The directors' report of this Company for the half-year ending December 31 states that the revenue amounted to £106,168, and the working expenses to £21,623. After providing £3,200 for debenture interest and sinking fund, and £1,706 for income tax, there remains a balance of £79,639, to which is added £4,410 brought forward, making a total of £84,049. First and second interim dividends, amounting to £39,000, have been paid, and £30,000 transferred to the reserve fund, leaving £15,049 to be carried to the next account. The receipts include £1,500 dividend to June 30 last on the Company's shares in the African Direct Telegraph Company, Limited. The various sections of the lines are in good working order. The shareholders' meeting takes place on the 13th inst.

SUBMARINE CABLES TRUST.

The annual meeting of certificate-holders was held last week at Winchester House, E.C., the Marquis of Tweeddale presiding.

After referring with regret to the absence of Sir John Pender, who had occupied the chair at every previous meeting, the **Chairman** proposed the adoption of the report, remarking that on the whole the year had been a prosperous one. The revenue had

Digitized by Google

been £22,313, or an increase over that of the previous year of £849. This was owing to the larger dividend which had been received from their investment in the Anglo-American Telegraph Company. The total expenses for the year had been £1,099, or £95 less than in the previous year. Their revenue had enabled them to pay the equivalent of two coupons of £3 each and clear off an additional 5s. of the remaining portion of the overdue coupon, still leaving a balance of £1 in arrear, which there was every reason to anticipate would soon be extinguished.

Mr. J. Denison Pender seconded the adoption of the report, and it was carried unanimously.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadtrath, Prague.

Penaranda de Bracamonte.—Tenders for electric lighting of the town for a period of 15 years may be sent to the authorities at the Casa Consistoria, Peneranda de Bracamonte, Spain, by May 28.

Bruges.—Tenders are wanted by May 13 for the supply and erection of an electric water-level indicator for the River Lys. Particulars from Le Gouvernement Provincial, Bruges, Belgium.

Chapelle-lez-Herlaimont.—Tenders are wanted by May 15 for erecting three lightning conductors on the Hôtel Communal. Address, M. le Bourgmestre, Chappelle lez-Herlaimont, Belgium

Spezia (Italy).—Tenders are wanted by May 11 by the Torpedo and Electric Department at the Spezia Arsenal and Dockyard for the supply of a quantity of copper and brass in wire sheets, and nails, etc.

South African Republic (Transvaal).—The Consul-General of the South African Republic at Amsterdam will receive tenders up to May 15 for the supply of 10,000 insulators and supports for the telegraphs of the republic.

Paris.—Tenders will be received by the Prefect of the Seine at the Paris Tribunal de Commerce on May 23 for the installation and working for 10 years of the electric light at the Hospice de Brévannes. The estimate is about £5,533, and the maximum annual payment 27,000f. (about £1,080).

Bray (Ireland).—The Town Council want tenders by May 17 for (1) a steam alternator, 75 kilowatts; (2) a Lancashire boiler, 200 h.p.; (3) economiser and feed-pump; (4) a vertical high-speed engine. Specifications, etc., can be obtained from Mr. P. MacDonnell, town clerk's office, Town Hall, Bray, on deposit of two guineas.

Portsmouth.—The Guardians of the Portsea Island Union invite tenders for wiring part of the main building of the workhouse for lighting by electricity. Specifications and all other particulars can be obtained from the Superintendent, Portsmouth Corporation Electricity Supply, Gunwharf-road. Tenders must be sent to the workhouse before 4 p.m on 13th inst.

Bucharest.—The Administration of the Roumanian Posts and Telegraphs at Bucharest want tenders by May 15 for the supply of about 21½ tons of bronze and copper wire and a quantity of fastenings. Tenders are wanted by the Municipal Administration of Bucharest by June 24 for a concession for lighting the city for a period of five years. A security of 15,000 lei (about £600) will be required.

Oldham.—Tenders are wanted by May 12 for an engine and dynamo of 360 h.p. from makers only who have previously constructed dynamos of that size. Particulars of Mr. A. Andrew, Gas and Water Offices, Oldham. The Electric Light Committee also want tenders for one Lancashire steam boiler 28ft. long and 7½ft. diameter, to work at a pressure of 125lb. A copy of the specification may be obtained on application to Mr. Andrew, to whom tenders are to be sent by May 12.

London, E.C.—The Great Eastern Railway require tenders for telegraph materials, etc. Forms of tender may be had on application to the Secretary's Office, Liverpool-street Terminus, E C. The patterns may be seen at the Company's Stores, Stratford, between 10 a m and 4 p.m. up till the 13th inst. The company's patterns cannot be sent away for inspection. Tenders, endorsed "Tender for Stores," to be forwarded by post to Mr T. D. Genlloud, secretary, Liverpool-street Terminus London, E.C., so as to be received by 10 a.m on 14th inst.

Wakefield.—Tenders are invited for the construction and erection of Contract No. 2, electric lighting buildings, etc., at Calder Vale, Wakefield, for the Council Plans and specification may be seen and bill of quantities and form of tender obtained (on payment of £1. 1s., to be returned on receipt of bona fide tender) at the office of Mr. R. Porter, city surveyor, Town Hall, Wakefield. Tenders for the whole of the works, or for the works comprised in each separate trade, addressed to the Town Clerk, Town Hall, Wakefield, should be delivered by 13th inst, endorsed "Tender for Contract No. 2."

Hammersmith (London).—The Vestry want tenders for the following: (*a*) the supplying and laying of high pressure and low-pressure cables and pipes; (*b*) the supply and erection of arc lamps and lamp-posts; (*c*) the supply and erection of transformers and sub-station equipment; (*d*) the supply and erection of a five-ton overhead travelling crane. Specifications, general condition, and form of tender can be obtained at the office of Mr. A. H. Preece, 39, Victoria-street, Westminster. Applications for any one or all of the above sections must be accompanied by a cheque for £2. 2s. which will be refunded on receipt of a bona fide tender. Sealed tenders, endorsed "Cables," "Arc Lamps," "Transformers," or "Crane," must be delivered at the offices of the Vestry, 57, Fulham Palace-road, Hammersmith, by noon on 27th inst. Mr. W. P. Cockburn, vestry clerk.

Coventry.—The Electric Lighting Committee require tenders for the supply and erection of the following plant: (Section A) boiler-house plant—boilers and fittings, mechanical stokers and economiser, feed pump, etc.; (Section B) engine-house plant—steam-engine, alternator, oil filter, fittings, etc., steam, exhaust, feed blow-off, sundry pipes, valves, etc. Tenderers are at liberty to tender for either section, but not for part of a section. The ground plan of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on payment of £2. 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to Mr. Lewis Beard, town clerk, St. Mary's Hall, Coventry, and delivered by May 12.

RESULTS OF TENDERS.

London.—For the construction of a section of the Central London Railway the tender of W. Scott and Co., Newcastle-on-Tyne, has been accepted.

Leeds.—At a meeting of the Tramways Sub-Committee of the Leeds Corporation tenders have been opened for the supply of about 1,000 tons of rails which are required for the relaying of the tramway lines along portions of the proposed electrical tramway route from Roundhay to Kirkstall. There were a dozen tenders sent in, the prices ranging from £6. 9s. per ton down to £5. 15s. The committee decided to recommend the acceptance of the tender of Mr. Leonard Cooper, whose quotation for the rails was £5. 15s. per ton. There will be a small allowance in addition for fastenings.

Hull. — The Electric Light Committee have received the following tenders for the supply of coal from the 1st inst. to December 31, 1896: A. Bannister and Co., 11s. 4d. (accepted); Denaby Main Colliery Company, Limited, 11s. 1d.; Hickleton Main Colliery Company, Limited, Thurnscoe, near Rotherham, 11s. 2d.; Hoyland Silkstone Coal and Coke Company, Limited, near Barnsley, 11s. 8d.; G. D. Strachan, 11s. 6d., 11s. 8d., and 11s. 8d.; M. Strachan and Son, 11s. 4d., 11s. 2d.; Sylvester and Co., Eastcheap-buildings, London, E.C., 11s. 2d.; W. Thorp, 11s. 7d. Rest of Hull.

Bradford.—The following tenders were accepted for the erection of a building required for the new electricity station at the junction of Valley-road and Lionel-street in the borough, for the Bradford Corporation. Mr. Thomas Barker, A M.I.C.E., 5, Bond-street, Bradford, architect:

J. Moulson and Sons, Bower-street, masons	£7,350
H. Thirkhill, Ripley-street, joiner	810
Hill and Nelson, Edmund-street, slaters	810
Roberts and Co., Limited, Dudley-hill, ironfounders	1,188
R. Townsend, Croft-street, plumber and glazier	333
T. Bolton, Tudor-street, plasterer and concretor	395
G. J. Walton, Horton-road, painter	117
Wood Block Flooring Company, London, flooring	55
Coalbrookdale Company, Salop, gates and railings	124
Rest of Bradford.	

BUSINESS NOTES.

Wakefield.—The electric light has been inaugurated at Belle Vue.

Merthyr.—The provisional order for electric lighting has been granted.

Direct Spanish Telegraph Company.—For the month of April the receipts were £2,422.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,583.

Great Northern Telegraph Company.—For the month of April the receipts were £23,200.

Manchester.—The Town Council have decided to apply for power to borrow £100,000 for extending the electric light.

Bangor (N. Wales).—The Board of Trade have refused the license applied for by the Town Council for lighting the city electrically.

Eastern Telegraph Company.—The receipts for the month of April were £72,824, as against £67,046 for the corresponding period of 1895.

Cheltenham.—A scheme is on foot to run a light railway to Cheltenham, taking in the Cleeve Common Golf Links, and then on to Winchcombe.

Eastern Extension Telegraph Company.—For the month of April the receipts show an increase of £9,356 as compared with the corresponding period of 1895.

Walsall.—The General Purposes Committee will submit for formal adoption at the next Town Council a resolution for acquiring the tramway lines within the borough.

West India and Panama Telegraph Company.—For the two weeks ended April 30 the receipts were £2,776, as against £2,656 for the corresponding period of 1895.

Digitized by Google

Paddington.—At the last meeting of the Vestry a proposal to obtain estimates for lighting the workhouse chapel by electricity for three months was adjourned for six weeks.

West Hartlepool.—Another satisfactory trial of the cars on the electric tramways took place the other day, exciting considerable public interest. The service will shortly commence.

Lydd.—An electrical plant has been laid down near the camp for the purpose of working the search light. This will be used for heavy gun firing practice at various objects at night-time.

North Staffordshire Tramways Company.—The annual supper of the employés of this Company took place at Shelton last Wednesday evening. Mr. W. J. Carruthers Wain, chairman of the directors, presided.

Chichester.—A company has been registered by Messrs. C. Doubble, 14, Serjeants'-inn, E.C., with a capital of £12,000 in £5 shares in order to construct and work a tramway between the city of Chichester and Selsey.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending May 3 amounted to £1,145, as compared with £1,148 in the corresponding week of the previous year, being a decrease of £3.

Battersea (London).—The Board of Trade have decided to grant a provisional order to the Battersea Vestry authorising them to supply electricity within the area of their jurisdiction. The order authorises the expenditure of £50,000.

Blackpool.—The *Blackpool Times* says that the electricity works will probably show a profit of nearly £300 on the year's working, and congratulates Mr. Hesketh on the fact that he has been able to "turn the corner" before he leaves.

Douglas (Isle of Man).—The laying of the lines of the Southern Electric Tramways is practically finished. The electrical machinery is on the ground and the boilers are being placed in position, with a view to opening the lines for traffic in June.

Islington (London).—To-day (Friday) the Vestry have to consider a report of committee recommending the laying of extra mains, the extension of the station, and the provision of extra plant. The total expenditure recommended is over £37,000.

Barrow-in-Furness.—During the week the borough has been visited by Mr. Manville, M.I.E.E., of the firm of Kincaid, Waller, and Manville, electrical engineers, who have been asked to inspect and report on the question of a public electric installation for Barrow.

Lynn.—The Provisional Orders No. 1 Bill, which confirms certain orders made by the Board of Trade under the Electric Lighting Acts of 1882 and 1888, relating, among other places, to Lynn, has passed the Committee on Unopposed Bills in the House of Commons.

Brighton.—The Bill to extend the time for the completion of the Brighton and Rottingdean Seashore Electric Tramroad to July, 1898, met with no opposition before the Examiner on Standing Orders in the House of Lords, and it was ordered to be reported for second reading.

Telescriptor Syndicate, Limited.—This Company has been registered, with a capital of £40,000 in £1 shares, to enter into an agreement with B. Hoffmann for the acquisition of certain patents relating to improvements in telegraphic apparatus and typewriting machines.

Grimsby.—The Electric Lighting Committee have after much discussion agreed to recommend to the Council that, as soon as the provisional order lapses, they apply for a renewal and also that the sub-committee be empowered to visit other towns for information in the meantime. The Town Council have adopted this report.

New Companies and Electric Work.—The following new companies take power to make electric tramways, or undertake other electric or telegraphic work—viz., the Barberton Consolidated Gold Fields, Limited; the Rhodesia-Sebakwé Development Syndicate, Limited; and the Barrow Bay (Canada) Estate and Manufacturing Company, Limited.

City and South London Railway.—The returns for the week ended May 3 were £878, compared with £864 for the corresponding period of last year, being an increase of £14. The total receipts for the half-year terminating as above were £17 027, compared with £16,983 in the same period of the preceding year, being an increase of £44.

Hammersmith.—The Electric Lighting Committee of the Vestry have reported that the plans for the new electric lighting station had been prepared, and the Vestry passed them. Upon the recommendation of the committee it was also agreed to purchase three rectifiers from Messrs. Ferranti at the price set out in their tender, £1,044. 15s.

Country-House Lighting.—We are informed that Captain Wingfield Stratford, of Woolton, has placed with Messrs. Drake and Gorham, 66, Victoria-street, Westminster, the contract for the electric lighting of his country house. There will be a petroleum engine, latest pattern dynamo, and 53 D.P. cells.

St. Pancras.—The Electricity Committee of the Vestry have reported that a profit of £6,575. 15s. 4d. has been made on the year's trading. This is equivalent to a return of 6 per cent. on the capital outlay. The Vestry have sanctioned the expenditure of £450 in putting down another boiler at the destructor.

Middlesbrough.—At a meeting of the Electric Lighting Committee a report from Mr. Hammond, engineer, was read in favour of electric lighting for the town. He recommended an installation at a cost of £21,000. After the matter had been fully discussed, the recommendation was negatived, two voting for it and eight against.

Peterborough.—At a meeting of the Town Council the following resolution was defeated, after much heated discussion: "That in view of the information acquired by the Council since January 28, 1896, it is undesirable to proceed at present with the application for leave to borrow £20,000 for electric lighting supply, and that such application be therefore withdrawn."

Canterbury.—The Town Council have decided to adopt the electric light, and have appointed an engineer to prepare plans for the necessary works. They have also agreed to apply to the Local Government Board for authority to raise a loan of £20,000 for the purpose. It is expected that the cathedral will be one of the first buildings in the city to be illuminated by electricity.

Bury St. Edmunds.—At the meeting of the Guardians a letter was received from the Eastern Counties' manager associated with the National Telephone Company stating it was contemplated to establish a telephonic exchange at Bury St. Edmunds, and asking whether the Thingoe Board would subscribe and have communication established with the workhouse. The application was declined.

Appointment Vacant.—The Governors of the East London Technical College, in connection with the People's Palace, are about to appoint a professor of physics for classes in connection with laboratory work in electricity, sound, heat, and light. The salary is £150 per annum, with a capitation fee, and attendance is required on two afternoons and four evenings a week during the session.

Alderley Edge (Cheshire).—A company has been registered, with a capital of £30,000 in £1 shares, to enter into an agreement with the Alderley Edge Urban District Council for the transfer of the provisional order granted by the Board of Trade for the generation and supply of electricity within the said district, and to carry on the general business of electrical engineers and suppliers of electricity.

Liverpool Meter Company, Limited.—This is the title of a new company registered by T. T. Hull, 22, Chancery-lane, W.C., with a capital of £30,000 in £1 shares, to carry into effect an agreement made between the Wirral Engineering Company, Limited, W. Alexander and W. E. Thompson, P. L. Birley, and the Company; and to carry on the businesses of gas engineers, electricians, and general engineers, etc.

International Improved Electric Company, Limited.—This Company has been registered with a capital of £75,000, divided into 75,000 shares of £1 each, to carry into effect an agreement made between Ferdinand Fanta and S. A. Bartlett, on behalf of this Company, to acquire the benefit of inventions for improved electric incandescent lamps, and the letters patent in respect to them. The registered office is 1, Arundel-street, Strand.

Taylor and Field.—Mr. J. H. Field, who in recent years has had charge of the equipment of several important installations in Scotland, has now entered into partnership with Mr. F. H. Taylor, late of 17, Ironmonger-lane. The new firm have their offices in 14, Victoria-street, Westminster, and will undertake all classes of wiring work and the laying down of isolated plant for the generation of electricity for private and manufacturing purposes.

Aberdeen.—The Town Council have decided to proceed with an extension of the electric lighting works at an estimated cost of £4,500, and that two new boilers, with water-heater and feed-pumps, be obtained at an outlay of £3,000. It was also agreed that the main should be extended from Union-street round Golden-square at an expenditure of £300, and the main in George-street, for a distance of 40 yards beyond the Northern Hall, at an expense of £280.

Central London Railway.—At the Guildhall, Westminster, last Saturday, before Mr. Troutbeck, the deputy high bailiff of Westminster, and a jury, the case of the Rev. C. G. Anderson *v.* the Central London Railway Company came on for hearing. It was a claim against the company for the sum of £8,464 as compensation for freehold premises, 15, Argyll-street, Oxford-street, required by the company for the construction of the Oxford-circus railway station. The jury assessed the compensation at £8,085.

Belper.—At a special meeting of the Urban District Council Mr. Smedley said he was not now prepared to go on with his proposal that they should apply to the Board of Trade for a license to adopt the electric light for the town, as the Council did not see their way to treat with the gas company. He was now of opinion that they had better get the water question settled, and he should never agree to the electric light being adopted without the other proposal going along with it. The motion to apply was therefore withdrawn.

Newington (London).—The Board of Trade having refused to sanction an application of the Vestry for a provisional order to supply electricity in the parish, it was believed that the refusal was due to an idea that the order, if granted, would not be carried into effect, and therefore Mr. Smithers moved a resolution stating that the order would be carried out if obtained. On a division this was passed by only 23 to 21, but the majority being so narrow it was decided not to send a deputation to the Board of Trade on the subject.

Fife.—At a meeting of the Road Board it was recommended that they construct a telephone system to and from the following places: Cupar, Dunfermline, Dysart, Lochgelly, Springfield, Ladybank, Markinch, Thornton, Leven, Kirkcaldy, Burntisland, Aberdour, St. Andrews, Cowdenbeath, Newburgh, and Newport. The total distance would be 81 miles, and the cost per mile was estimated at £12 11s. 10d. It was resolved to send a memorandum to other county councils in Scotland detailing what had been done

Digitized by Google

in Fifeshire, and urging them to join in pressing the Government on the subject.

Chelmsford.—At a meeting of the Town Council the Lighting Committee reported that they had considered the specifications of the lighting plant, etc., from Messrs. Crompton and Co, in reference to the purchase of the electric lighting undertaking, and also a letter received from the company, dated March 23, in which they stated they were prepared to sell the undertaking, including the provisional order, works, machinery, mains, and the business as a going concern for £34,328. The committee recommended that authority be given them to consult an expert before coming to any conclusion. The Council adopted the recommendation.

Bolton.—The Joint Committee (the Streets and Electric Lighting Committees) have considered the memorandum of the deputation which has been to Bristol and Walsall to inspect the electric trams there, and have resolved that it is desirable electrical traction should be adopted for the working by the Corporation of the tramways, that in the opinion of the sub-committee the overhead system should be adopted, and that the lessee of the tramways be invited to confer with this sub-committee as to commencing the adoption of the system. The Council have adopted this report, and the system will be tried on the Daubhill section of the lines.

Electrolytic Gold Winning in West Australia.—At the (statutory) general meeting of the Sugarloaf 25-Mile Cement Leases Company, held in the City, Mr. H. W. Lowe (the chairman of the company), in reply to a shareholder said the machinery ordered for the mine was not on the ordinary process, but was a process of electrolysis with the separation of the gold by means of electricity. It was cheaper than any other machinery, and was well worth a trial. If it answered well they could enlarge their plant later on, and if it did not answer they would in the meantime have derived the benefit of other experiments and would be ready to adopt some other process. The amount of outlay was so small that it would not be a very serious matter either to renew or to change their plant.

Derby.—The Electric Lighting Committee reported at the meeting of the Town Council that two new transformers have been ordered from Messrs. Siemens Bros. at a cost of £268. A 1½-h p. motor has been ordered for coal hauling at a cost of £32. Messrs. Siemens Bros. have presented to the committee 200 yards of arc light cable. Three hundred and fifty yards of high-tension cable have been purchased from the British Insulated Wire Company at a cost of £49. 14s. 4d. The Local Government Board have declined to sanction the borrowing of the sum of £419, being the costs incurred in obtaining the electric lighting provisional order. The Local Government Board have held an enquiry as to the borrowing of moneys upon the electric lighting account. Their decision has not yet been received. The tender of the British Insulated Wire Company for cables, junction-boxes, and jointing, amounting to £2 185, has been accepted.

Dover.—At the meeting of the Town Council, Councillor G. F. Fry said he wished to give notice of motion for the next Council meeting He noticed in the papers that the tramway question was coming to the front, therefore he hoped that the Town Council would, before entering on a large expenditure that this undertaking would involve, take steps to obtain the best information. His motion would be to the effect that the Mayor, the deputy mayor, the surveyor, and some gentleman representing the other side of the House—perhaps Mr. Bradley—should go to Rouen, where 25 miles of tramways had been laid down on the overhead system, which seemed to be the best system in existence. He thought that if that were done, the gentlemen would be able to advise the Council as to the propriety of going on with the tramways, and as to what character they should be. The Mayor asked if the motion could not be so worded as to enable them to go to any other place, and this was agreed to. The Board of Trade have approved the proposed tramway scheme.

Chelsea Electricity Supply Company.—The directors of the Chelsea Electricity Supply Company, Limited, have announced the issue, at a premium of £2 per share, of 12,000 ordinary £5 shares, ranking for dividend at the rate of 2½ per cent. per annum until December 31 next from the due dates of the respective instalments, exclusive of the premium, after which they will rank with the existing shares. The prospectus states that the Company supplies electricity on a continuous system in the parish of Chelsea, and last year had a gross revenue £17,165, as against £6,080 in 1890. A dividend of 2½ per cent. was paid on the ordinary shares in 1892, and 5 per cent. in each of the succeeding three years. The authorised share capital is £200 500, divided into 34,000 ordinary and 6,000 6 per cent. preference £5 shares, and 500 founders' £1 shares. The preference and founders' shares have all been issued, and 14,000 of the ordinary shares, the whole being fully paid up. There has also been issued £60,000 4½ per cent. debenture stock. The list of subscriptions opened on Thursday, and closes to-day (Friday).

Kensington.—The Works and Sanitary Committee have had before them the revised regulations made by the Board of Trade for securing the safety of the public and for ensuring a proper and sufficient supply of electrical energy which are imposed upon the respective electric lighting companies in this parish, together with reports by the surveyor and lighting engineer thereon. The committee have reported that the regulations themselves do not appear to call for any special action on the part of the Vestry, but it has been pointed out that the Vestry may, subject to the approval of the Board of Trade, make by-laws for further securing the safety of the public. The committee were of opinion that the Vestry might take advantage of this power to ensure that the regulations of the Board of Trade above referred to are duly regarded; and they accordingly recommended that a by-law be made under Section 6 of the Electric Lighting Act, 1882, as follows: "The electric lighting companies having areas of supply in the parish of Kensington shall once at least in every six months furnish to the Vestry a report setting forth the action taken by them for complying with the regulations made by the Board of Trade."

Bray (Ireland).—At the meeting of the Commissioners, a letter was read from Messrs Molloy and Molloy, solicitors, with reference to postponing the consideration of the electric tramway scheme for six months, pointing out that the action of the Commissioners in so doing meant that they could not hear the application of the promoters, as a grand jury, before this time next year. They therefore asked the Commissioners to pass such a resolution as would permit them to avail of the extension of time clauses in the Tramway (Ireland) Act, 1883 and proceed under that Act at the next summer assizes. The Chairman said he was as anxious as any gentleman in the township for the prosperity of Bray. He had given the question of the proposed tramways a great deal of consideration, and he would wish to ask those who were in favour of the scheme was Bray a place that was likely to grow into a large commercial centre, or a place for fashionable people to come and reside? If they permitted the trams to be laid, there would be a block in the traffic in the narrow part of the streets. Captain Patrickson said he was going to propose a motion in favour of the trams, but after what the chairman had said he would not do so. It was ultimately decided not to take any action in the matter, in view of the resolution passed at the last meeting with reference to the subject.

Croydon.—At the meeting of the Corporation the General Purposes Committee reported that they had considered a report from Prof. Kennedy as to the arc lighting, the report stating that the professor, having gone into the question in some detail, finds that it is not possible with such a scheme as he thinks the Council would be well advised to adopt to include arc lighting under the original loan. The additional expenditure necessary for carrying out the scheme as now recommended by the professor will be about £1,500. Prof. Kennedy suggests that if further borrowing powers be obtained, it would be advisable to obtain sufficient to cover the cost of putting up a condensing plant and the pipes connected with it, as well as the permanent chimney The cost of the whole of these works, including the £1,500 as above, would be about £4,700. Upon the suggestion of the Electric Lighting Sub-Committee, who had considered this matter, the committee recommended that the Council should apply to the Local Government Board for sanction to a further loan of £5,000 on account of the foregoing works. The committee further recommended that in view of the extension of the electric light to areas outside that at present proposed to be lighted, and for which a demand had already sprung up, the Council should seek the sanction of the Local Government Board for a further loan of £5,000 on this account.

Exeter.—At the meeting of the Governors of the Devon and Exeter Hospital Colonel Lucas stated that the machinery and apparatus required for the new laundry could also be used for generating electricity. Veale and Co., St. Austell, estimated the cost of installing the light at £896, but contingencies would bring the total up to £1,195 The medical staff were in favour of the electric light. The cost of working would be about £190 a year, or £50 less than the cost of their gas. There would also be a saving in renewing pipes, and in painting and whitewashing to the extent, it was thought, of nearly £200 a year. The committee strongly recommended the adoption of the light, and he moved that £1.000 be obtained to carry out the installation. Mr. Franklin seconded, and the report was adopted by 22 votes to 3. At a meeting of the City Council the Town Clerk read the following communication, dated April 28, from Mr. T. W. L. Pelham, of the Local Government Board: "Exeter Electric Lighting Order, 1891.—With reference to previous correspondence on the subject of the above-mentioned order, I am directed by the Board of Trade to inform you that they have revoked the order, and to transmit to you, for the information of the Corporation of Exeter, the enclosed notice of revocation. I am, at the same time, to refer you to the provisions of Section 68 of the order with reference to the time within which notice requiring the undertakers to sell the undertaking should be served upon them." On the motion of Mr. Wreford, it was resolved that the application be made requiring the undertakers to sell the undertaking as from June 30.

Fulham.—At a meeting of the Electric Lighting Committee, the report drawn up by Mr Medhurst with reference to the electric lighting of the borough and providing a dust destructor was considered. Mr. Drew said that there did not seem any occasion for them to hurry on the matter. Having regard to the fact that they were on the eve of an election, and that it was quite possible that some of them might not return to the Vestry, he thought that it would be the best for that business to stand over until the new committee had been formed. It might perhaps go before the Lighting Committee. However, he moved that the matter be allowed to stand over until after the new Vestry had been elected. Mr. R E. Cranfield seconded the motion, and said at the same time he hoped that the matter would certainly not go before the Lighting Committee. If the question was going to be referred to them, there would not be a member who would really know anything about it, because they were so irregular in their attendance. He hoped that the matter would be sent to the new committee. Mr. Drew's motion was put by the Chairman to the committee, and declared carried. Mr. C. Thomas attended as a member of the Vestry, and read a report of the working of the electric light in Westminster. That system, he said, if adopted, would save the ratepayers the sum of £7,000. He had no interest in the concern, but simply brought it before the committee for

Digitized by Google

their consideration. Mr. F. H. Medhurst said that he did not think that the system adopted at Westminster could be used at Fulham with any success. Ultimately Mr. Thomas's recommendation was referred to the surveyor to consider.

York.—At the quarterly meeting of the City Council it was stated that Prof. Kennedy had attended before the Streets and Buildings Committee, and discussed in detail the report which he had submitted respecting the electric lighting of the city, and the committee resolved that he be requested to prepare a specification for the electric lighting of the city with a view to tenders being obtained for the supply and fixing of the necessary plant. Mr. Lambert moved as an amendment that "the public debt of the city having reached approximately £500,000, owing chiefly to the extravagance of the School Board and the extraordinary cost of the new sewerage scheme, it is undesirable to enter upon any new scheme such as the adoption of an electric lighting system under municipal management, and that the resolution to keep the electric lighting of the city in the hands of the Corporation be rescinded." He said that many towns about the size of York that had adopted electric lighting had lost on the undertaking. Mr. Brown seconded the amendment. Mr. Purnell said many towns had made considerable profit even on the first year's working, and he believed that the electric lighting of the city would pay, and ought to be undertaken by the Corporation rather than by a private company. Alderman Wragge thought it would be most suicidal to pass the amendment when the committee had been instructed by the Council to report and prepare specifications for which the Council would have to pay 100 guineas. Mr. H. V Scott said there were 31 companies lighting towns, and 29 of them were making large profits at the cost of the towns. After further discussion the amendment was defeated by 17 votes to 9, and the report was adopted.

Belfast.—At a meeting of the Law and Improvement Committee the Belfast Street Tramway Company's application for a provisional order was discussed at length. It was elicited during the proceedings that at the present time the tramway company's lines in the city and suburbs cover an extent of 20 miles, and that their gross receipts last year totalled £103,000, 8 per cent. on which would amount to £8,200, whereas the Corporation are receiving £4,000 from the company. Ultimately it was moved that the tramway company be informed that whilst approving of the order in Council as amended making it permissive, the Corporation would not give their consent to the doubling of the lines under the order unless the company would pay a yearly rent of £200 per mile for such additional mileage. The resolution was carried, with a few dissentients. At the quarterly meeting of the Corporation, a deputation attended from the Trades Council urging the necessity for early tramway extension at the cost of the Corporation Councillor George Andrews moved the adoption of the report of the Electric Committee, which contained the following: "Your committee have under consideration the probable extension of the electric lighting system and the consequent necessity of providing a suitable site for a station capable of accommodating the plant required, but they are not yet in a position to make any definite recommendations on the subject." Councillor Andrews said the committee had under consideration the erection of a steam generating station, so that they might be in a position to supply electric current to the whole of the city. They hoped to lay a report on the matter before the Council on June 1 next. They had considered the question of site, but there were some little difficulties in the matter that they would like to have settled before they came forward with a report. They would have to ask the Corporation for land, or for money to purchase land. Councillor Jaffé seconded the motion, which was passed.

Cardiff—A new industrial and fine-art exhibition has just been opened, and contains a fine display of electrical and telegraphic machinery and apparatus. The total space taken up by the engineering and electrical section is about two-fifths of the total area covered by the buildings. It consists of the western bay of the main building, which is a space equal to that of the mining and agricultural sections put together, and it also includes a minor annexe, in which are the electric lighting engines. In the centre of the building comes the electric lighting plant, which consists of four pairs of engines all compound and one pair of vertical engines. There are also a large horizontal main engine and two pairs of smaller engines for stand by's and supplementary work. These engines all serve the double purpose of being exhibits and working the electric lighting machinery. There are five dynamos and two exciters driven by a countershaft between the dynamos and the engine; in other words, the engine drives the countershaft and the latter the dynamos. The engines will drive up to 200 arc and 600 incandescent lights, the latter being mostly of 16 c.p. The engines are supplied with steam from two batteries of two multitubular boilers by Babcock and Wilcox. These are calculated to give, if required, 1,000 h.p. In addition to these boilers there is one small battery of boilers put in by Messrs. Hornsby, of Grantham, that is to be used as a kind of stand-by. A steam-pipe from these main boilers supplies first the electric plant, and then steam to a pair of Braithwaite's high-speed engines, which go at a pace of something over 400 revolutions, and drive the main shafting at 180 revolutions per minute. These are calculated to give 200 h.p. if required. At a meeting of the Executive Council on Monday Mr. J. H. Hallett submitted the offer of a gentleman to provide a search-light and run it, on condition that the electric current was provided. The subject was referred to the Machinery Committee.

Bristol.—At a special meeting of the Town Council, Councillor Pearson moved the adoption of the report of the Electrical Committee, and asked the Council to go on with the extension of the station, a work which would ultimately cost £75,000. When the station was complete they would have on the site something like 5,000 h.p., and they could place additional dynamos up to 1,000 h.p., either for motive power or arc lighting in the streets. The public lighting had practically remained the same from the beginning, but the private demand had increased most satisfactorily, until they estimated that the revenue for the year ending September 1896, from private consumption would be nearly £6,500. The committee desired to induce the Council to increase the supply as required, the committee believing that the public demand was far from exhausted. The result of the trading of the last half-year was that, after paying all the expenses of the station, interest, and the sinking fund, a profit had been made of about £1 500, and they proposed to use this to meet the deficiency which was likely to ensue in the present half-year, when, on the account of the long days, there was less demand for the light. The department now cost the city nothing, and the time was gone when any demand would be made. With regard to what they intended to do with the money, they purposed in the building to divide it into three yearly instalments The estimated cost they reckoned at £74,735, and therefore they thought it well to ask for £75,000. When these works were complete, they would, if necessary, be able to supply the whole of the tramway service with motive power without adding another brick to their station or another tile to their roof. They had said nothing in the report as to the arc lighting, because the committee were not responsible for that; but if the Council were to ask for an extension of the street-lighting they would extend it in the direction indicated, and bring up an estimate of the expenditure and the revenue. He hoped that the committee would receive the support of the Council, because he thought the public-spirited way in which the citizens had taken up the light justified the attempt they were making to increase it Councillor Tryon seconded the resolution, which was carried, after some discussion. The further extension of the system in the streets was referred to the committee.

Lighting Picture Galleries.—In connection with Sir Noel Paton's great picture "De Profundis," which is now being exhibited at Messrs. Grindley and Palmer's Galleries, Church-street, Liverpool, it may be mentioned that their premises have been completely renovated. One of the most interesting features of the alterations is the new electric light installation, which has been carried out by Mr. Charles Rettie, of 18, Geraint-street, Liverpool. The old installation, which only consisted of a very few lights, has been replaced by an entirely new plant, consisting of 119 lights. This installation is of rather more than usual interest, as it marks another departure in the use of the electric light. Up to the present time picture dealers and others have been rather prejudiced against the use of the electric light. They admitted its superiority over all other illuminants as far as cleanliness and preservation were concerned, but on account of the supposed glare thrown on the pictures (especially on large exhibition pictures) they prohibited its use. That prejudice has apparently quite disappeared, as the present action of Messrs. Grindley and Palmer proves. The installation is carried out on the distributing system, and is thoroughly up to date. It is divided into four main sections, which are divided again into several small sections distinctly separate from each other, the whole being controlled by two D.P. switches 50 amperes and 25 amperes respectively. Too much stress cannot be made on this point, as it is not generally known that the mere fact of turning off the lights does not necessarily stop the current, and unless double-pole switches were inserted in the system so as to completely sever both wires when leaving premises at night, a fire might break out at any moment. This fact is laid down in the Phœnix rules, but is seldom taken notice of, the usual thing being to switch off by a single-pole switch (at the meter) put in by the supply company or corporation. There are also six sectional 25-ampere switches, as well as a small switch to every light or cluster. There are three large switchboards, made of black St. Anne's marble, which contain all the switches and D.P. cut-outs. There are no fittings shown on the walls, except in the workshop, basement, storerooms, and window. All the fittings were made to order, and are specially designed jointly by Messrs. Grindley and Palmer and Mr. Rettie As regards the lighting of the picture, it is all that could be desired, and is a great success. The fitting which is used is very simple and portable, and can be taken down by any of the shop assistants when exhibition is over without any skilled knowledge. Mr. Rettie can claim to be the first to introduce permanently the electric light in Liverpool for exhibiting large pictures, the first being the "Saving of the Colours," by Mr. R. Gibb, R.S.A., which was exhibited by Mr. Dunthorne in his Rembrandt Art Gallery, Castle-street, Liverpool. This is the first large installation carried out under the new Board of Trade rules, and it was subjected to a severe test by a small alternating machine which will test up to 300 volts, and was entirely satisfactory. Most of the wires were one night flooded with water, caused by the bursting of a water-pipe in an adjoining building, and the test showed more than double the requirements of the 1896 rules of the Phœnix Fire Office.

PROVISIONAL PATENTS, 1896.

APRIL 27.

8892. Improvements in and relating to switchboards to be used for telephonic purposes. Charles Shore and Charles Heap, Old Market-chambers, Yorkshire-street, Rochdale.

NOTES.

Dynamo and Transformer Construction.—Mr. James Swinburne, M.I.E.E., will commence a course of lectures on this subject on June 2 at the Electrical Standardising, Testing, and Training Institution, Charing Cross-road.

Another Exhibition.—We have received the *Boletin de la Union Industrial Argentina* for April. It deals with the trade of the Argentine Republic and Bolivia, etc., and discusses editorially the question of an industrial exhibition at Buenos Ayres.

King's College.—The annual dinner of old students of King's College, London, has been fixed to be held at the Holborn Restaurant on Monday, June 29. Sir Benjamin Baker, K.C.M.G., F.R.S., president of the Institution of Civil Engineers, will take the chair.

Telephones.—The *Daily Mail* says that it is in contemplation to lay down wires so that it will be possible to erect temporary telephone stations in the Mall and in Birdcage-walk in connection with the palace on drawing-room days, so as to greatly facilitate and abbreviate the business of calling the carriages.

A Present from the Sultan.—It is stated in the Constantinople newspapers that the Sultan has ordered an electric motor launch, built at the Imperial dockyard at Constantinople, should be presented to the Prince of Bulgaria. And yet there are people that complain that the Sublime Porte is not up to date.

Telephone Poles.—The *Zeitschrift für Elektrotechnik*, in the course of an account of the central telephone exchange at Brünn, in Moravia, describes the poles used to carry the wires in the neighbourhood of the exchange. These are iron constructions of the lattice type. They are over 50ft. high, and carry about 120 lines on 12 cross-pieces.

Royal Institution.—The Duke of Northumberland, president of the Royal Institution, has appointed the following as vice-presidents for 1896-97: Sir Frederick Abel, Lord Kelvin, Mr. George Matthey, F.R.S., Mr. Ludwig Mond, Earl Percy, Mr. Basil Woodd Smith, Sir James Crichton-Browne, treasurer, and Sir Frederick Bramwell, hon. secretary.

Pamphlets Received.—We have received "Lighting, Heating, and Cooking," a reprint of articles in the *Sanitary Record*, and note that in it the sanitary advantages of electric cooking are insisted on. We are also in receipt of *Compressed Air*, a new American monthly, whose title indicates the subject with which it deals. The English office is 114A, Queen Victoria-street.

Telephone Working.—The *Elektrotechnischer Zeitschrift* of May 7 devotes its "Review" to Mr. Dane Sinclair's paper at the Institution of Electrical Engineers on the working of a telephone exchange. A summary of the paper and discussion is given, but our contemporary has little to say editorially on the subject. Mr. Preece's remarks on the excellent working of the Berlin telephone exchange are, of course, duly noted.

Paper Poles.—It is possible to make a great many things out of paper, or out of a substance which is not paper, but can without any very great stretch of veracity be called so. We are therefore told in the *Moniteur Industriel* that telegraph poles may be made out of paper. The pulp is to be compressed hydraulically, and borax, salt, and other substances added. The advantages are to be lightness and durability. Unfortunately, these paper promises seldom come off.

Attenuating Toxines.—From the proceedings of the Imperial Russian Association of Industries it would appear that Mr. W. A. Tjurin has been repeating with success the French experiments on the attenuation of toxines by means of alternating currents. He states that under the influence of the current the virulence of diphtheria toxine can be so reduced that guinea-pigs inoculated with it show hardly any symptoms of its action, while if instead the untreated toxine is injected they die in a day. The attenuated toxine acts as a prophylactic and the animals inoculated with it cannot afterwards be made to contract the disease.

Units.—The *Journal Officiel* has published the order of the French Government fixing and rendering obligatory the use in all transactions in connection with the public service of the "electric units accepted practically by all the great nations." The obligatory units are the ohm (referred to a mercury standard "at the temperature of melting glass"), the volt (sufficiently represented by ·6974 of the E.M.F. o a Clark cell), the ampere, farad, coulomb, henry, joule, an watt. The unit of light is "the quantity of light emitted normal to the surface by a square centimetre of platinum at the melting point." Rules are given for the construction of the Clark cell.

Electricity in Theatres.—In the *Elektrotechnische Zeitschrift* there has appeared an exceedingly long article by Dr. O. Feuerlein on the use of electric light in theatres—that is, not for lighting the auditorium, but behind the scenes. Work done by Messrs. Siemens and Halske is described, and a quantity of incandescent lamps contained in metallic reflectors are figured. These are protected with wire network, just as though they were gas-jets—surely a superfluity of precaution. After a brief reference to the possibilities of the application of electricity to stage machinery, it is concluded that in the end an electric installation will be a necessity for every theatre.

A Telegraph Tale.—There are always a quantity of telegraph stories going about. The following one is represented as having been told by Sir Robert Low as an example of the difficulties he had with the field telegraph in the Chitral campaign. The native chiefs were at first rather suspicious of the wire, as they thought it was a mark for parcelling out the country among the soldiers, but on being told that it was to send messages to India they agreed to guard it. As, however, they did not see any messages passing along, they cut off a couple of miles of wire and took it away to watch the messages more at their ease. Their investigations were interrupted by the return of the engineers to see what had happened to the wire and why communications were cut.

Accident.—An accident, though fortunately not of serious character, appears to have happened in connection with the Portsmouth electric lighting on Sunday last According to the *Daily News*, a cabman named George Foote was passing an electric lamp column in Hyde-park-road, Portsmouth, "when the door of the column suddenly flew open and touched his head." Foote immediately fell, and was subsequently taken to the hospital. At the electric light works it is suggested that the accident was caused by gas escaping from the main finding its way into the electric lighting column, and being ignited by the spark caused by the contact of the automatic apparatus for switching on the incandescent lamps an explosion resulted, the door being forced opened and striking Foote violently.

Motorcarts.—The "International Exhibition of Motors, and Congress of Motor Industries, Horseless Carriages and Cars, Self-Propelled and other Vehicles, Cycles, Stationary Motors, Appliances, and Inventions" at the Imperial Institute was opened last Saturday. We have already referred to the

Digitized by Google

chief features of this show in an account of the preliminary private view. It may be added that besides the motorcarts there are a quantity of "flying" machines. It is said that Mr. Maxim would have shown his entire apparatus if it had not been for fear of difficulties with the London County Council. If so, that body will again not be thanked. However, the engine is shown and a model on a small scale. The Prince of Wales was present in the evening. It may be mentioned that the Royal Agricultural Society will give prizes for light and heavy motorcarts at their next year's show.

Electrical Warfare.—Some time ago all the American papers that did not know anything of electricity were telling us of the terrible things to be done by Mr. Edison to the armies and fleets of any country that should dare to resist the Great Republic. The European nations were not greatly alarmed, and in France, where they have no proper reverence, there were some who laughed. But in Switzerland they have done better, though it has taken them some time. The *Journal de Genève* has just published a veracious discovery made there that bullets are diverted by the presence of telegraph wires carrying a current. Armour plates and fortifications will evidently go out of use when, with a few cheap telegraph wires, the enemy's shot can be turned away to the right and the left. Of the wonders of electricity, as reported in the non-technical Press, there is indeed no end.

Outside v. Tram Car.—The Dublin and Dalkey Tramway Company, while waiting for the permission of the Board of Trade to open the line, have taken advantage of the interval to train their motor men and conductors, and for this purpose the cars have been running daily, no passengers, of course, being taken. An outside car man, who naturally thought that there was nothing like horse-flesh, having observed the empty cars, remarked to his fare, "These new trams 'll never do." "Why?" was the inevitable question. "Sure, Sir, they've been runnin' them for the past month, and the divil a passenger they had at all; the public won't thrust 'em. And how are they goin' to pay their way at that rate. There's nothin' like an outsider, Sir." But perhaps he only wanted to delude an ignorant "Saxon" after all. To make anyone prefer an outside car because it was a "safe" conveyance would rank high in the scale of blarney even among such accomplished practitioners as the Dublin car men.

Institution of Civil Engineers.—A committee has been appointed to consider the question of the definition of a standard or standards of thermal efficiency for steam-engines, and the following gentlemen have been nominated members: Dr. Alexander B. W. Kennedy, member of council, and Mr. T. Hudson Beare, Mr. Bryan Donkin, Mr. James A. Ewing, Mr. J. Macfarlane Gray, Mr. Michael Longridge, Mr. W. H. Maw, and Mr. H. Riall Sankey. In connection with the Bill of the Government for power for the acquisition of land in connection with what is known as "the Parliament-street site," for the improvement and widening of Parliament-street and the obtaining of a site on which to build public offices, the institution has presented a petition, but they made no appearances against the Bill. Mr. Cameron, however, stated in the House of Commons last Monday a clause had been inserted for the protection of the institution, and the Bill was ordered to be reported to the House. The annual general meeting to receive the report and elect officers for the ensuing year will take place on June 2 at 8 p.m. The dinner of present and past students of the institution is to be held at the Restaurant Frascati, Oxford-street, to-day (Friday) at 7.30. Sir Benjamin Baker will preside. At next Tuesday's meeting papers on the magnetic testing of iron are to be read.

The Telephone Service.—Sir Blundell Maple having asked the Secretary to the Treasury, as representing the Postmaster-General in the House of Commons, if the Post Office was now prepared to give the same facilities for using trunk telephone lines, with respect to hours of service, etc., as existed previous to the Post Office taking over these lines, Mr. Hanbury replied that north of the Thames the former facilities remained, as the company still worked their old trunk wires. The facilities with respect to hours of service under Post Office control were now being given experimentally at certain places in the South of England, and the experiment was about to be extended. Until the result was known he would not be in a position to give any pledge as to a permanent arrangement, but there was strong reason to hope that the result would be satisfactory. This may be satisfactory to Mr. Hanbury, but will hardly be so to the general public. When a Government not only undertakes a business, but forbids anyone else doing so in competition, it is their obvious duty, if the public is not to suffer, to provide at least as good a service as any private undertaker would. Of course, a Government can always do this if it works on business lines, since it enjoys advantages which the private undertaking does not possess. If it were not so, it would be best for governments not to undertake such work.

Niagara in New York.—Last week, in mentioning the subject of the transmission of power from Niagara Falls to New York, we referred to the proposition to enable people at the electrical exposition in that city to listen to the "roar" of Niagara. We are again indebted to the New York *Electrical Engineer* for details as to what the American Telephone and Telegraph Company intend to do in this direction. It is said to be an often tested fact that over the long-distance wires, even now, although not arranged for the purpose, the noise of the falls can sometimes be heard, and the company are making plans so that several people can hear it distinctly at any hour and all at once. It is not necessary in making connection at the falls to go behind the sheet of water in order to get the full effect of sound, but by placing the transmitter near the Horseshoe on the Canadian shore all the tone and quality will, it is said, be clearly obtained. The receivers, to the number of 30 or 40, will be grouped around the little model of the Niagara power plant, on the special central platform, in the main hall of the New York Exposition, so that people will see Niagara run and hear it at the same time, the model itself being also driven with live or stored current from the falls, as explained last week. Mr. F. A. Pickernell, the electrical engineer of the American Telephone and Telegraph Company, is making the arrangments for this entertainment, which will be open to all visitors to the exposition.

A Registering Econometer.—In the *Revue Industrielle* there is a description of an Arndt econometer, to which is attached an electromagnetic registering apparatus. The Arndt econometer is an instrument for measuring the proportion of carbonic acid present in, say, chimney gases by weighing a fixed volume of them contained in a bulb against a quantity of air at the same temperature. The two bulbs are carried on the arms of a light and very sensitive balance, and the chimney gas being of a greater specific gravity than air at the same temperature, the gas bulb has an opening at the bottom and the gas is delivered into it by a tube passing through this orifice and sucked out again by an aspirator. The registering apparatus is of the usual type—that is, there are a quantity of circuits, one only of which is complete according to the position of a contact-maker carried on one of the arms of the balance. The

Digitized by Google

circuit, when made, actuates a marker on a revolving drum by means of an electromagnet in the usual manner. It will be seen at once, however, that with a delicate balance such as is required there is no power to spare, and that the difference of weight on the two arms would be absolutely inefficient as a means of overcoming the friction of the contact-piece. The arms must hang free, and yet contact must be made. The difficulty is got over by making the contacts intermittent, the contact-maker being attracted by an electromagnet actuated by an intermittent current. A good momentary contact can thus be made, and yet the balance be left absolutely free to move up or down during the intervals between the contacts. Practice alone can show how such an apparatus will work, but the intermittent contact arrangement ought to act as a very efficient "dead-beat."

The Junior Engineers.—At the meeting of the Institution of Junior Engineers, held at the Westminster Palace Hotel, last Friday, the chairman, Mr. H. J. Young, presiding, a paper, "Notes on Belgian Electrical Engineering Practice," was read by Mr. A. Anstruther-Thomson and Mr. G. C. Allingham. The communication embodied particulars which had been collected by the authors during the institution's summer meeting of last year. Belgian electrical practice, the authors said, was difficult to define exactly. While it was usual to associate English practice, with high-speed engines direct coupled to dynamos or alternators, and Continental, with slow-speed engines driving multipolar dynamos; no rigid distinction existed. Belgian practice appeared strongly to exhibit both the foregoing characteristics, and was therefore extremely interesting as showing a variety of types, and affording exceptional opportunities for comparison. In contrasting English with foreign practice, the advantages of employing a consulting engineer over the foreign plan of giving the contract for the complete plant to some large firm were insisted on, and it was remarked that the system of free publication of central-station accounts to which in this country we were accustomed was not adopted in Belgium. Originally high-speed dynamos were driven from slow-speed engines by belts. To secure the advantages of direct coupling, in England the engine speed was increased, whilst on the Continent the dynamo speed was diminished. After briefly touching on the term "load-factor" and its influence on central-station practice, the preference shown on the Continent for continuous-current and large batteries was pointed out. Descriptions were given of some Belgian central stations, the Van Rysselberghe system at Antwerp and the application of gas-engines in sub-stations at Brussels being specially mentioned. The different types of plant in use in Belgium and England having then been dealt with, including boilers, engines, steam-turbines, dynamos, and batteries, it was remarked that with regard to electricity for power purposes there were no long-distance transmissions in Belgium, and hardly any multiphase plant, but the use of electromotors in workshops was steadily increasing. Several instances were given, notably the important installation at the Herstal Small-Arms Factory. In reviewing the question of electric traction, after referring to the Belgian experiments on accumulator cars, the trolley system, in which American designs are naturally largely employed, was considered, and descriptions of two Belgian electric tramways were given. The conclusion appeared to be that in electrical practice Belgium occupied a position intermediate between England and the Continent. The authors finally expressed their appreciation of the excursion to Belgium, and the hope that the institution would organise other meetings abroad; to their Belgian hosts their hearty thanks were due for the exceedingly kind reception which had been extended. A discussion followed, in which Messrs. H. B. Vorley, W. B. Clarke, F. M. Short, A. H. Dykes, T. E. Dowse, and K. Edgcumbe took part.

Rontgen Radiations.—A curious report has appeared in the *Standard* with reference to the possibility of the Röntgen rays being directly visible. On physiological grounds it is exceedingly unlikely that they should be so, but since they affect the photographic plate it is not absolutely impossible that they should likewise affect the retina, and it must be remembered that the *Standard's* Berlin correspondent, from whom the report comes, has hitherto been exceedingly accurate and up-to-date in all that he has telegraphed on the subject. Under normal circumstances Röntgen radiations would not reach the retina, since from the observations made by Prof. Salvioni and others it appears that the lenses of the eye are practically opaque to them. This fact, according to our contemporary, suggested to Dr. Brandes, of the University of Halle, the idea of trying what would happen with a lensless eye. It is stated that the experiment having been tried with a girl who had undergone the operation for cataract, it was found that the Röntgen rays were visible to her. It is stated that an aluminium plate was interposed between the eye and the Crookes tube, so that it would not appear that there could be any confusion between the Röntgen rays and the light of the tube, although from another part of the account of the experiment this would be inclined to suggest itself. It is further added that, if sufficient precaution is taken to exclude all ordinary light, the new radiations can be perceived by the normal eye, apparently being transmitted, not through the lens, but through the region of the sclerotic. Of course, there can be no question of "seeing" with the Röntgen rays, since there is no refraction and consequently no image. All that is possible would be a sort of undefined sensation of light. Considering how easily even a careful observer may deceive himself in experiments of this nature conducted with new and unfamiliar apparatus, it is evident that all results must be accepted with extreme caution. If, however, Dr. Brandes's observations are reliable, it is tantalising that our contemporary's correspondent should have missed the importance of telegraphing what the colour of the rays was, and in particular whether it was the same as the greenish-yellow light given off by the tube. For the rest, Mr. J. G. Stokes has written to the *Standard* to say that he has taken Röntgen photographs using the sparks of a Wimshurst machine instead of a Crookes tube. That was done before, when Prof. Röntgen's discovery was quite a new one. The American electrical papers still have a great deal to say on the subject so far as space is concerned, but very little of what is new or important. Everyone is ready to suggest this or think that, but no one seems to make any serious effort to grapple with the difficulties which beset each of the three or four theories that have been put forward as to the nature of the new rays.

Electric Traction on Railways.—We have several times referred to the contributions of Mr. W. Baxter to the American technical Press on the subject of the substitution of electrical for steam traction on ordinary railways. Mr. Baxter does not consider that this would result in any very large saving of coal. But writing in the *Scientific American*, he adds: "Investigation shows that the average cost of fuel consumed by American railroads amounts to about 10 per cent. of the total operating expenses; therefore, a saving of even half the coal would not be sufficient to justify the expenditure that would be necessary to equip a road electrically." On the other hand, there are indirect gains. "It would not be doing justice to electricity

Digitized by Google

to assume that the only way in which it could reduce the operating expenses of a road would be by effecting a saving in coal, for such is clearly not the case. A little reflection will show that, if consumption of coal and water along the track is stopped, the wages of all men employed in preparing them for use can be saved, and also the cost of repairs to water-tanks, coal-bunkers, etc. It is also evident that the cost of keeping locomotives in repair is greater than the amount that would be expended on motors doing the same work. The boiler and tender have no counterpart in the electric motor, therefore all the money expended in keeping those parts of a locomotive in repair would have to be checked off in estimating the difference between the cost of maintenance of electric motors and locomotives." It seems to us, however, that the engines and boilers at the generating station will require looking after sometimes. Mr. Baxter further remarks that the smoothness of motion of the motor "ought to materially reduce the wear and tear of the rolling-stock as well as the roadway, and if the operation of trolley roads is anything to go by, the mileage of electric locomotives should be greater than that now covered by steam." The conclusion is that while it is far from certain that the net gain would be sufficient to pay the interest on the outlay that would be required to instal an electric plant on an existing railway, it might be enough to justify the adoption of the system for new lines. "Several branches of steam roads have been equipped electrically, and their operation has been so successful as to lead to the belief that in this direction electricity will obtain a foothold; but most, if not all, of these branches run light cars, about half-way between full-size steam cars and trolley cars, and therefore the results obtained on these branches are not a true indication of what could be done on the trunk lines with full-sized equipment." There is little to go by in America, and still less in Europe, as to what could be done with heavy traffic. In fact, the Baltimore and Ohio tunnel working is about all we have to judge from But Mr. Baxter thinks that this is fully sufficient to demonstrate that electric motors are capable of handling the heaviest kind of rail-road traffic, and if the future should show that they can do the work at a cost sufficiently below that of steam to render the saving in operating expenses 10 or 15 per cent., the prospects of the locomotive—at least, on new railways—will be anything but bright.

University of London.—In the House of Commons last week, Sir A. Rollit asked the Vice-President of the Council whether it was intended to introduce a Bill in pursuance of the recommendations, with or without modifications, of the Gresham Commission for the reorganisation of the University of London; and, if so, when and in which House. In reply to this, Sir J. Gorst said the Bill was being prepared in the Privy Council Office, but had not yet received the sanction of the Government. When it had received that sanction it would probably be introduced in the House of Lords. In view of the prospects of a Bill introduced after Whitsuntide if there is any great amount of opposition to it, a letter to the *Times* written by Prof. Ramsay from Madeira is important. The letter is too long for reproduction here, but in it Prof. Ramsay says: "An amount of agreement, amounting practically to unanimity, has been arrived at amongst the various conflicting interests concerned, which would have appeared quite hopeless of attainment to those who had to take up the tangled threads of this intricate problem in 1892. Seldom on any great public question, involving many interests and affecting many institutions, has so remarkable a consensus of opinion been expressed as that which was submitted to the Duke of Devonshire by the deputation which waited on him in November last, when the accredited representatives of the various bodies concerned, hitherto at hopeless variance amongst themselves, united in asking for a Bill, similar to that introduced by Lord Playfair under the late Government, to give effect to the recommendations of the Gresham Commission. The fragment of doubt suggested by the Duke as to the true meaning of recent votes in the Convocation of London University, to which it appeared to the deputation at the time that exaggerated importance was being attached, has now been removed by the decisive vote in Convocation itself, and no obstacle now remains in the way of a settlement of this long controversy by the addition to the present examining functions of the London University of those teaching functions which will convert it into a university worthy of its name and of the Metropolis of this great empire." The difficulty, of course, is to decide what difference, if any, should be made in the examination between resident and non-resident students. In this respect the recommendations speak for themselves. They leave it to the Senate, after consultation with the Academic Council and the standing Board, to decide to what extent the examinations shall be the same for both kinds of student. They contemplate, as a possible arrangement, that the examinations shall be wholly the same, but lay it down, as the extreme limit of diversity, that the final examinations, at any rate, shall be identical for both so far as identity may not prove to be prejudicial to either. Such a solution Prof. Ramsay considers should satisfy the advocates of either view. "It would have been unwise for the Commissioners to express themselves more rigidly on a point as to which strong difference of opinion among experts calls for some elasticity of treatment, while their main object would have been defeated if they had not insisted on conditions which will insure the indispensable identity of qualification. The interests of the external student will be safeguarded by the existence of a special board to take charge of them; those of the internal student will be safe in the hands of the Academic Council." A meeting of convocation of the university on Tuesday last was not without its absurd side. It seems that the examiner is fallible after all, and that at the University of London the examiners have been most grievously invading the province of the examinee, which is to make blunders. Anyhow, Mr. H. J. Harris, B.A., in moving a number of resolutions recommended by the Annual Committee, chiefly with respect to the new syllabus in mathematics, remarked that it was a disgrace to the university "that in four questions there should have been eight errors," and to his knowledge grievous injustice had been done to candidates who had failed to pass, largely in consequence of this discreditable blundering. Mr. Harris did not propose to examine the examiners, but one of his resolutions was, "That some means should be devised for a more thorough preliminary investigation than has hitherto been usual of the mathematical questions proposed to be set in the university examinations." Sir. A. Rollit, M.P., deprecated the taking of a division on such a subject. Of course, this is just the sort of thing that a great many people think should never be confessed openly, and an animated discussion followed. Dr. Silvanus Thompson has had something to say on the subject before, and now, naturally, strenuously supported the resolutions. The evil, he said, was understated, and the number of blunders in papers on mixed mathematics and other subjects was an absolute scandal; there were even errata in the errata. Ultimately, Mr. Harris's resolution was agreed to by a large majority.

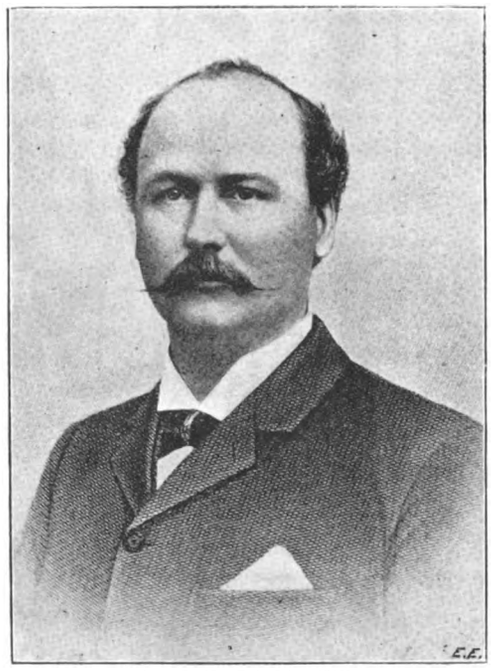
DUBLIN ELECTRIC TRAMWAYS.

The electric tramway between Dublin and Dalkey, which has been equipped by the above-named company, is one which will form a striking landmark in the history of electrical railways in this country. The line, which at present is not connected to the heart of Dublin, commences at Haddington-road, about half a mile from the centre of the city. From there it runs to the Royal Irish Society's show grounds, Ballsbridge, at which point the generating station of the company has been erected. The line then passes along Salisbury-road, through Merrion and Booterstown, to Williamstown and Blackrock. In this last extensive suburb a sub-station, as at Dalkey, has been erected. Onward from this point the line becomes most romantic in its surroundings. The sea view on one side is enhanced by the lovely country traversed as the line passes through Monkstown and Kingstown to Sandycove and Dalkey. At Sandycove a splendid view of the small harbour there is obtained, and the end of the line at Dalkey is surrounded by picturesque ruins.

MR. GEO. WHITE,
Chairman of the Dublin Southern District Tramway Company.



MR. J. CLIFTON ROBINSON,
Managing Director and Engineer to the Company.

The history of the tramways has been marked more by the fighting spirit of the Irish nation than by a desire to provide for the convenience of the public. The eight route miles of line were originally owned by four distinct companies, each running its own independent section, so that a passenger in going from Dublin to Dalkey had frequently to change cars no less than three times. There was also a change of gauge, so that even on holidays through cars could not be run. While this fighting *régime* lasted profit and progress were impossible, and the first object of the new directorate when

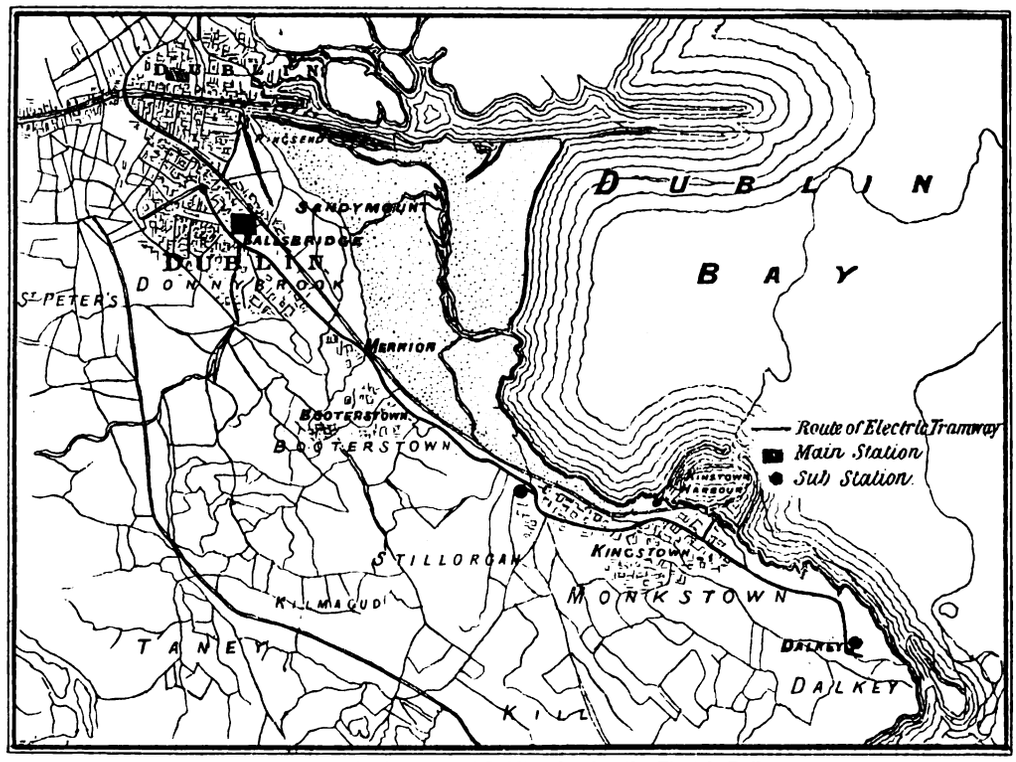


FIG. 1.—Map of the Environs of Dublin, showing the Electric Railway.

Digitized by Google

they obtained control of the lines in 1892 was to inaugurate a regular through traffic with through fares. Though they were hampered by the disadvantages of horse traffic and a correspondingly slow service, the working soon showed a profit. The new directors, under the able chairmanship of Mr. George White, of Bristol, then determined to equip the line electrically on the overhead trolley system, and in 1893 obtained legal and parliamentary powers to enable them to introduce electricity on their lines. The work of reorganising and converting the tramway was placed in the energetic hands of Mr. Clifton Robinson, managing director and electrical engineer to the company, assisted by Mr. H. F. Parshall as consulting engineer. The fame of the latter gentleman as an electrical designer in America will assure the general reader that the electrical equipment of the line would be well carried out. In this work Mr. Parshall has included a three-phase transmission of power which forms the first extensive application of this system in the United Kingdom. Mr. Clifton Robinson's well-known skill as an organiser and his indomitable spirit in the face of opposition have been strongly brought out at Dublin. No expense has been spared to make the civil engineering work in connection with the laying of the permanent way a success, and the whole equipment of the lines has been provided for on the broad-minded policy that the convenience of the passengers and the easy travelling of the cars are the first desiderata. The civil engineering work has been carried out by Mr. S. G. Fraser, C.E.

FIG. 2.—Electric Trams at Monkstown.

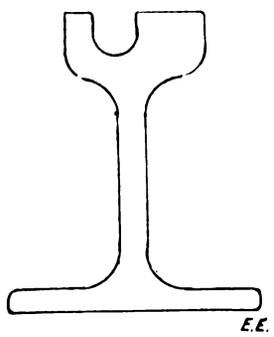

FIG. 3.—Section of Girder Rail.

The great sources of revenue to be anticipated from past experience in connection with the line are, first, the regular traffic of bringing business men from their suburban residences into the city of Dublin, and, secondly, the holiday and tourist traffic. The whole of the country passed through by the line in running from Dublin through Kingstown to Dalkey consists of a series of rich suburban districts, with gentlemen's houses standing in their own grounds. The outlook over Dublin Bay is one that has rendered this part of the coast exceedingly popular as a residential locality, hence, with a regular service in the morning and evening at five-minute intervals, with the fares given below, there is little doubt that a large and regular patronage on the part of business men will be acquired. The frequency of the service precludes the necessity of catching any individual car, and renders access into Dublin by tramway as speedy and certain as by the Dublin, Wicklow, and Wexford Railway. Moreover, when the extensions now under consideration by Parliament are passed—as most likely will be the case in a few weeks' time—the electric cars will provide convenient access to all parts of the city. The holiday traffic, judging from the picturesque surroundings of the line, not to mention the sea breezes to be enjoyed on the top of the cars, should be extensive, and a ride from Haddington-road to Dalkey at 4d.—*i.e.*, at less than ½d. a mile—will commend itself to residents and tourists alike. The following list of fares charged by the electric tramway and the corresponding railway fares will show the reader that the tramway company mean to provide for the public most liberally.

COMPARATIVE SCHEDULE OF FARES.

Dublin Electric Tramways Company.			Corresponding railway fares.		
Sections.	Present fares.	Old fares.	3rd-class single.	2nd class single.	1st-class single.
	d.	d.	d.	d.	s. d.
Haddington-road to Merrion	1	2	1	2	0 5
Merrion to Blackrock		2	1	2	
Blackrock to Kingstown		3	2	3	0 8
Kingstown to Dalkey		2	2	3	
Haddington-road to Blackrock	2	3	3	5	1 0
Merrion to Kingstown		5	3	5	
Blackrock to Dalkey		5	3	5	
Haddington-road to Kingstown	3	6	6	9	
Merrion Gates to Dalkey		7	5	8	
Haddington-road to Dalkey	4	8	8	10	1 4

Since the acquirement of the Blackrock and Kingstown Tramway in April, 1893, the average annual car mileage run is about 320,000 miles, while the number of passengers

Digitized by Google

carried per year approximates at 1,500,000. The Dublin, Wicklow, and Wexford Railway Company carry on an average 6,000,000 per annum, while their annual mileage is about 1,000,000. The annual dividend paid on the Kingstown section averages 9½ per cent, against 1½ per cent. for the entire system, and the traffic on the Kingstown

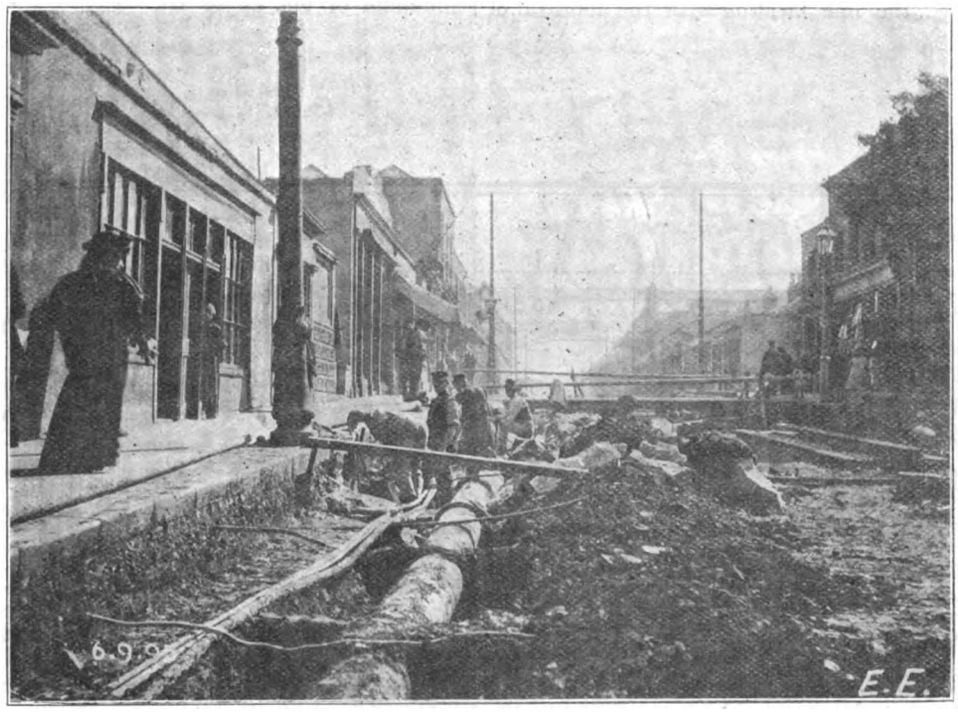

FIG. 4.—Excavation for Regrading the Main Street, Kingstown, showing Electric Feeders and Gas-Pipes.

Railway is said to yield a revenue of over £400 per mile per week.

GENERAL ARRANGEMENTS AND DESIGN.

The system on which the line is equipped is that of the overhead trolley so widely used in America.

wire being divided by sectional insulators. Along the full length of the line there is laid a feeder whose conductor has a sectional area of ·08 square inch. This feeder is connected to the half-mile section by means of the switch pillars placed at the foot of a post every half mile. The current in the trolley wire is supplied through this feeder at 500 volts. The feeder receives its supply at three points—*i.e.*, at the generating station at Ballsbridge and at the sub-stations at Blackrock and Dalkey. Instead of supplying these sub-stations by direct-current feeders, which would necessitate a large amount of copper, a three-phase alternating-current system has been adopted. The two

FIG. 5.—View of the Track at a Cross-over before the Granite Setts were laid

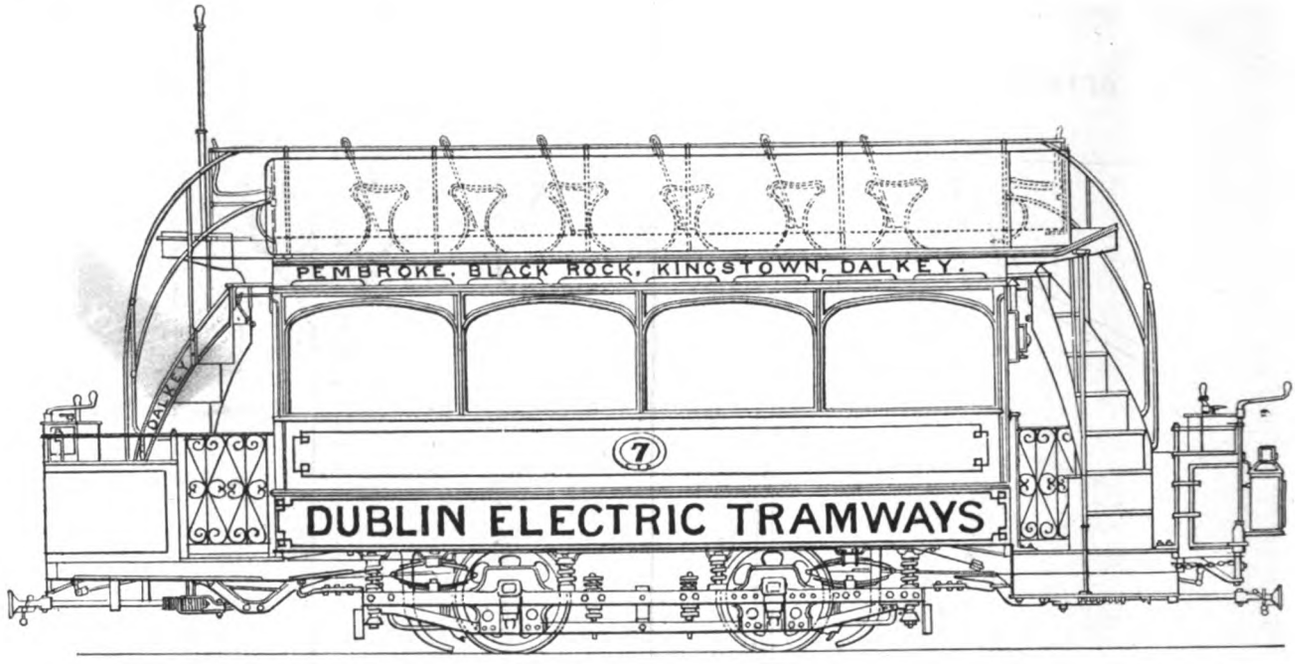
The latest and most approved practice has been followed generally, and as Mr. Parshall has been the consulting engineer we have a right to claim that in many respects the equipment is ahead of anything done on the other side. Thus the line, which is some eight miles long, is divided into half-mile sections, the trolley

alternators at Ballsbridge generate at from 2,000 to 2,500 volts, and the high-tension current is transmitted by two triple concentric cables to Blackrock and by one similar cable from Blackrock to Dalkey. The sectional area of the conductors in these cables is ·049 square inch.

At each of the sub-stations rotary transformers are used,

Digitized by Google

consisting of a 60-kilowatt three-phase motor direct coupled to an ordinary 500-volt direct-current dynamo. These dynamos supply the 500-volt feeders referred to above. The three-phase motors are synchronous, and hence well under control from the central station. The return circuit from the cars is made through the rails, which are carefully bonded with Chicago bonds. The careful attention to this work has ensured the line meeting with the approval of the Board of Trade. Thus it was found that the observed drop in volts on the rails between Ballsbridge and Dalkey when 50 amperes was applied at Dalkey agreed within 10 per cent. with the calculated value, and was well within the Board of Trade limit of seven volts. Both the tracks are bonded, and there are cross-bonds between them every 240ft.



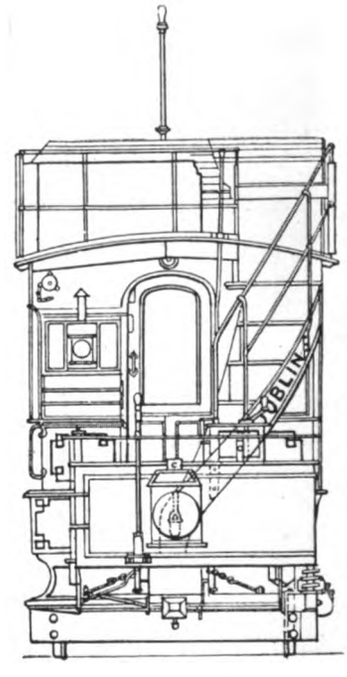
SIDE ELEVATION

FIG. 6.—Elevation of Motor Car used on the Dublin-Dalkey Electric Railway.

The contract for the whole of the work was placed with the British Thomson-Houston Company, and was directed from their head office in Parliament-street. The resident engineer in charge of the work has been Mr. C. W. G. Little, who, in spite of the various difficulties to be overcome, has carried it through most successfully.

CONSTRUCTION OF THE TRACK.

The first contract for this work was given to Mr. A. Krauss, of Bristol, but some dispute arising after the first few hundred yards had been laid the whole contract for the completion of the permanent way was placed with the Callender Bitumen Company on May 22, 1895. This contract included the removal of the old track, the excavation and new grading of the roads—the latter in many places necessitating the relaying of gas and water pipes. Besides this, the contract included the laying of the concrete bed, the supply and laying of the rail, and repaving. The gauge adopted is 5ft. 3in., which is the Irish standard, with 5ft. between the tracks. The rails are of the girder type, and are shown in section in Fig. 3. Substantial fishplates, weighing 25½lb. per pair, are used with eight bolts, the bond being placed clear of the fishplates. Tie-rods, weighing 14lb. each, connect the rails every 4ft. and maintain the gauge. These steel rails were specially rolled for Messrs. Callender and Co. by the Barrow Hematite Company. The spring points and crossings are of Marshall's patent design, supplied by Messrs. Askham Bros. and Wilson, of Sheffield. Sixty-two sets of points and crossings have been supplied for the work, which allows for four complete cross-overs per mile of double track. All the bending of the rails and blacksmith work were done on the spot. The worst curve on the line is one of 28ft. radius at the corner of Cassell-street, in Dalkey. The curve leading into the Royal Marine-road at Kingstown is of 31ft. radius. The worst grade on the line is one of 1 in 16 at Temple-hill, and there are short grades of 1 in 22, 1 in 24, and 1 in 30. After the roads had been regraded, as will be explained below, the concrete bed was made of broken granite from the old setts, mixed with Portland cement and sand or gravel crushings in the proportion of 6 to 1. The width of the concrete bed is 18ft., and the thickness varies from a minimum of 6in. up to 1ft. The bed was finally floated level with gravel and cement mixed in the proportion of 2 to 1. On this the granite setts are bedded in sand. The enormous quantity required will be gathered from the fact that 16,000 tons of trimmed granite has been supplied. The largest proportion of this came from Wales, being obtained from the granite quarries at Yr Eifl Llanaelhaiarn and Gwylwyr



END ELEVATION

FIG. 7.—End Elevation of Car.

y Wernnevan, near Carnarvon. A good number of setts were also obtained from Aberdeen and Dalbeattie, and a few hundred tons of Irish setts have also been used. The permanent way was grouted in with cement in most places, but at Kingstown pitch was used. The whole of the new track could easily have been completed in August last had it not been for the sewerage works carried out by the Kings-

Digitized by Google

town Commissioners. The Commissioners had been for years under the obligation to construct a new line of sewers, and awoke to action in the matter when a certain proportion of the work of the tramway had been completed.

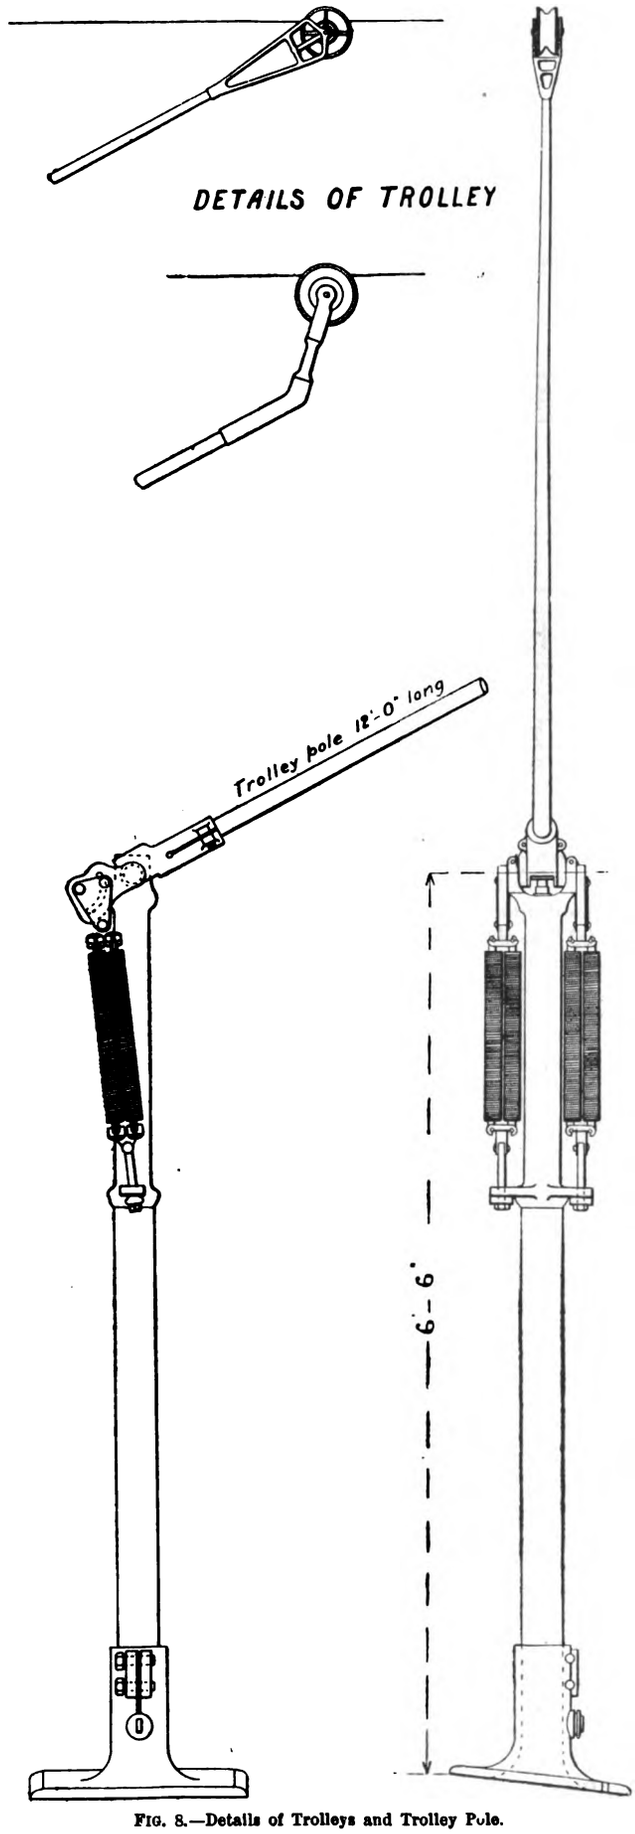


FIG. 8.—Details of Trolleys and Trolley Pole.

They had before this used the rights they had obtained over the tramway company to compel the latter to regrade the whole of the main street in Kingstown. The extent of this work will be gathered from the fact that the road was raised over 3ft. in Longford-place, and at other places, notably in Upper and Lower Green-street and Glasthule, the roadway was lowered an equal amount. When this work had been fairly proceeded with, the Commissioners commenced to lay their sewer, and the subsidence of the soil used to fill in the trench caused no small amount of trouble to the tramway engineers. From insufficient ramming and want of watering in the filling in, the soil proved utterly useless as a support for the concrete bed, and granite piers had to be erected,

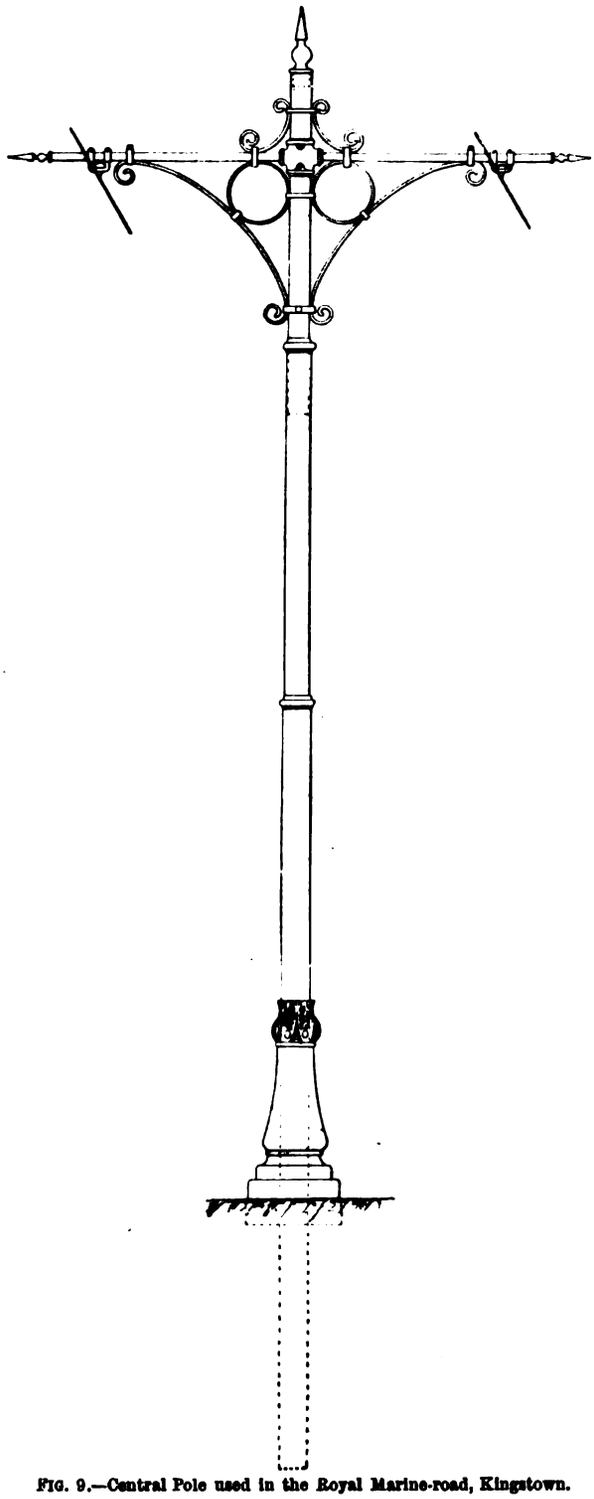

FIG. 9.—Central Pole used in the Royal Marine-road, Kingstown.

across which were placed pieces of old tramway rails to bear the weight of the new track. Through the whole of Kingstown the concrete bed had to be made 1ft. thick on account of the difficulty arising from the sewage works. In many places in Kingstown, in the new grading of the road, a large amount of rock had to be removed, and as, owing to the proximity of the houses, blasting was impossible, the process was exceedingly laborious. The whole of this work was carried out under the superintendence of Mr. T. Petersen, assistant manager of the Callender Company, with the help of Mr. Proctor and Mr.

Digitized by Google

Sandiford. The whole of the labour employed has been local, and the number of workmen at one time amounted to over a thousand, of whom 500 may be described as having been on the regular staff. The total length of track laid is 15¾ miles, which, in addition to 1¼ miles of old track in Monkstown, brings the total length up to 17 miles. The difficulties met with in the construction of the line are well shown in Fig. 4, while Fig. 5 shows the rails at a cross-over before the granite setts are placed in position.

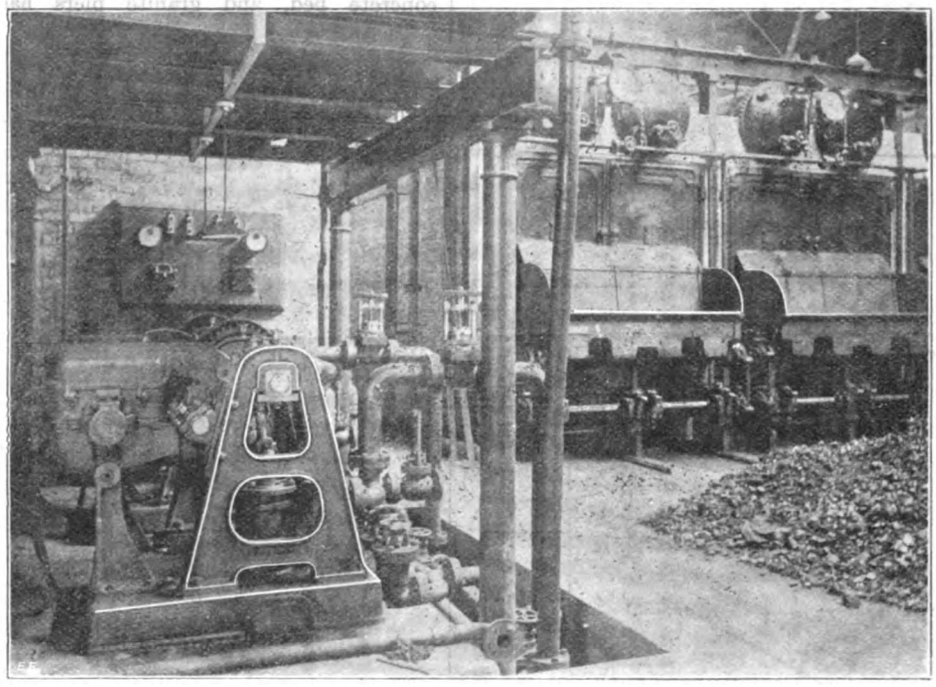

FIG. 10.—View of Boilers with Mechanical Stokers.

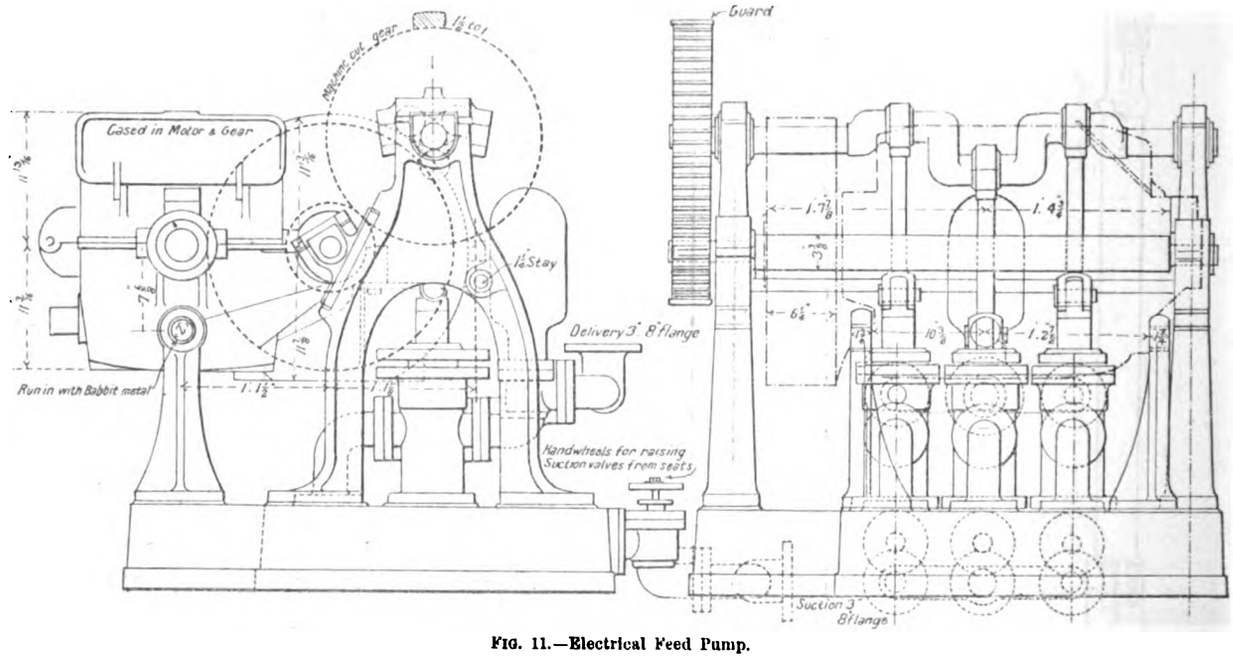
CONSTRUCTION OF THE MOTORCARS.

A view on a small scale of the car and trailer has been given in Fig. 2, but the full details of the cars will be more clearly seen in Figs. 6 and 7. It will be noticed that the cars and trailers are exceedingly roomy. The motorcars are built to accommodate 53 passengers, of whom 24 are carried inside, while the trailers have sufficient accommodation for 46 passengers—*i.e.*, 20 inside and 26 outside. The platforms at the back and front are well designed and give a separate entrance and exit for the inside and outside passengers. On the motorcars safety gates are also provided to prevent passengers boarding the cars at the end from which they are being driven. The access to the outside seats is easy, and electric bells are provided so that passengers on the top can stop the car at will. The cars are lighted by five incandescent lamps connected in series across the line, and in front of each motorcar a strong head-light will be carried after dark, which will illuminate the roadway for some distance ahead. A powerful hand-brake is fitted to each car, and in emergencies the motorcars can be quickly stopped by reversing the motors. The trucks are of the Peckham type, of which the general design will be seen from Fig. 6. They were manufactured for the contractors by Messrs. G. T. Milnes and Co., of Birkenhead. The motors used are of the G.E. 800 type, manufactured by the General Electric Company, of New York. They are guaranteed to give a horizontal effort of 800lb. with a 33in. car wheel when running at eight miles an hour.



Guard
Cased in Motor & Gear
Run in with Babbit metal
Delivery 3" B'flange
Handwheels for raising Suction valves from seats
Suction 3" B'flange

FIG. 11.—Electrical Feed Pump.

Two of these motors are used in each motorcar. They are protected by a steel casing, which is made waterproof. By careful construction, the weight of these 25-h.p. motors, complete with gearing, etc., is kept under 1,600lb. The armature coils are insulated with asbestos, so as to be fireproof, and the whole armature is waterproofed. The gear reduction is 4·78 to 1, the pinion being of steel, gearing into an iron wheel. The gear is, of course, contained in an

Digitized by Google

oil-tight case, and the lubrication has been made a special feature. The controllers used on the cars are of the General Electric K 2 series-parallel type, which have been described before in our columns. One of these is placed at each end of the car, and the driver always carries his handles with him. From an inspection of the working of these cars, for which we are indebted to the courtesy of Mr. Clifton Robinson, we are able fully to endorse the great value of these controllers, as with them the cars were always easily handled, and also the use of very large currents at starting was obviated. The trolley pole and trolley used at Dublin are shown in detail in Fig. 8. These trolleys in practice are found to work admirably, and on the severe curves found at Dalkey and Kingstown no trouble whatever has been encountered with them.

of hard-drawn copper, about ·325in. in diameter—No. 0 B. & S.—and, as explained above, it is divided into half-mile sections, and fed through switch-pillars from the 500-volt feeder which extends the full length of the line. Guard-wires are erected over the line wherever telegraph or telephone wires cross it.

Feeders.

The 500-volt feeder has been supplied and laid complete by Messrs. Callender and Co. The cable has been supplied in two sizes, one of $^{19}/_{\cdot 109}$ strand and the other $^{19}/_{\cdot 072}$ strand, the sectional area of the large cable being ·15 square inch and that of the smaller ·08. These cables are insulated with bituminised fibre, lead sheathed, yarned, and armoured by two steel tapes, and then yarned and

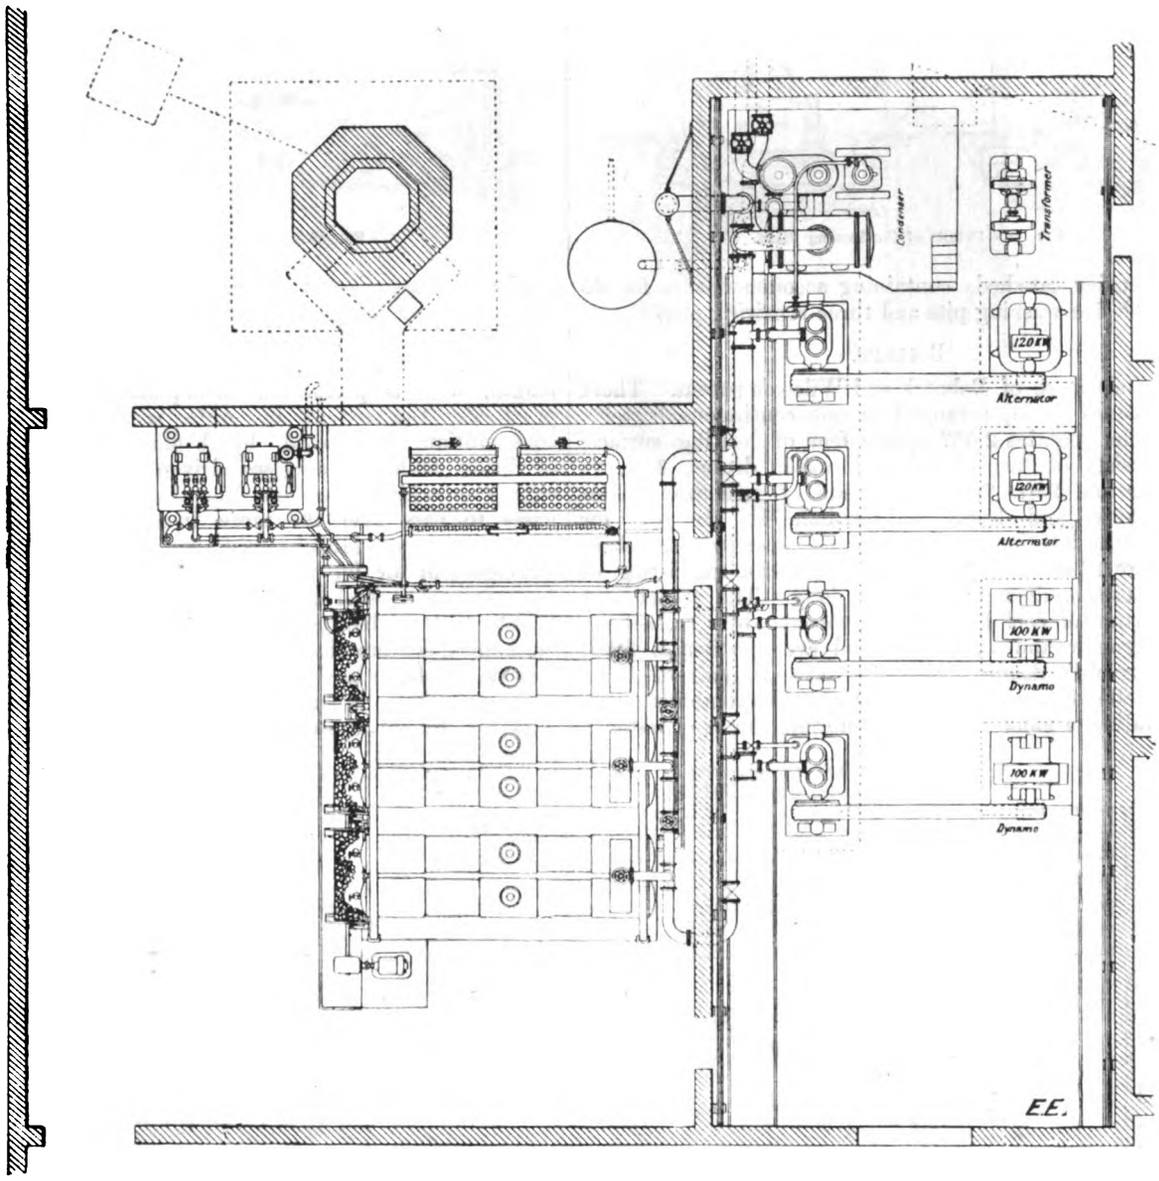


Fig. 12.—Plan of the Generating Station at Ball's Bridge, Dublin.

Overhead Construction.

With the exception of the Royal Marine-road, Kingstown, which is equipped on the central-pole system with poles as shown in Fig. 9, the whole of the overhead construction is arranged on the span-wire system. Two iron poles are placed one at each side of the road, and the span wire between the two, supports the insulators carrying the up and down wires. At the curves a second wire is often run between the two adjoining posts on the same side of the road, to keep the trolley wires approximately over the centre of the track. This can be seen in Fig. 2. The poles at the side of the road are made of steel tubes of three different sections, shrunk together at the junctions. They are bedded in concrete, a cast-iron base and foot-plate being fitted over the lower end of the pole. The span wires are mild steel, §in. in diameter. The trolley wire is

compounded over all. The steel tape used has been most carefully selected, in order to have great powers of resisting penetration. The factory lengths are jointed in cast-iron joint-boxes, so that a continuous iron sheath is provided throughout. Sixteen switch-pillars have been provided by the same firm, and the cable is looped into them, and not connected by means of T joints. Eight thousand yards of the larger-sized cable have been used, and 6,200 yards of the smaller. The larger-sized cable is used between Blackrock and Dalkey.

Pilot Wires.

The three-core pilot wire has also been laid by the same firm throughout the whole length of the line. Each conductor is a $^{7}/_{22}$ strand, and the three insulated cores are laid up together, lead-sheathed and armoured. This cable is used for testing purposes and to provide tele-

Digitized by Google

phonic communication between any section of the line and any sub-station. The whole of these mains, together with the high-tension alternating main referred to below, have been laid in a trench running along the footpath (see Fig. 4).

Generating Station.

The main generating station is situated at Ballsbridge adjoining the River Dodder, water from which will be used for condensing purposes. The station consists of a boiler-room, engine-room, accumulator-room, as well as workshops

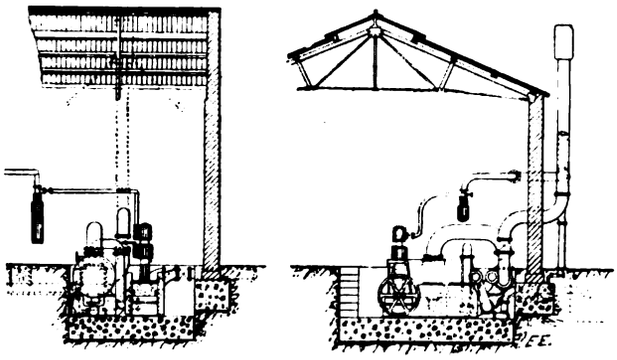

Fig. 13.—Details of Condensing Plant.

and extensive car-sheds containing accommodation for 46 cars, with five washing pits and three repairing pits.

Boilers.

The boilers are of Babcock and Wilcox's patent. There are three of them, arranged in one continuous battery. Each boiler contains 2,437 square feet of heating surface, and consists of two steam and water drums, 36in. in diameter and 23ft. 7in. long, made of mild-steel plates $\frac{13}{32}$in. thick, and having a manhole at the rear for access to the interior of each drum. Suspended from these drums are 12 sections of tubes, each section consisting of nine tubes 4in. diameter and 18ft. long. The steam and water drums of each boiler are connected by a cross-drum 20in. diameter and 72in. long, and every boiler is fitted with Turnbull's deadweight safety-valves, a pair of Dewrance's self-closing water-gauge fittings, two combined feed-check valves, a globe valve for regulating the feed water, a 2in. blow-off cock of Hopkinson's make, and a Hopkinson's 7in. main steam stop-valve fitted on the top with a cross-drum. In addition, each boiler is furnished with automatic fixed soot-cleaning pipes for enabling the soot to be blown from the exterior of the tubes by means of fixed steam-jets, and the fronts are fitted with large-sized tube doors, giving access to the front headers. The boilers are constructed for a daily working pressure of 160lb. per square inch, and were tested after erection to 240lb. At the present time, however, the safety-valves are only loaded to 140lb. The boiler fires are fed by Vicars's mechanical stokers specially arranged to work with this type of boiler. The fuel is fed from a hopper into four boxes, from which it is gradually pushed by alternately reciprocating plungers into a fireplace. Then it falls on to the dead-plates, and goes from there to the firebars, which by a slow reciprocating movement carry the burning mass gradually backward. Such unconsumed coal as reaches the end of the grate bars, together with the clinker and ash refuse carried back, are discharged over the ends of the firebars on to a set of short

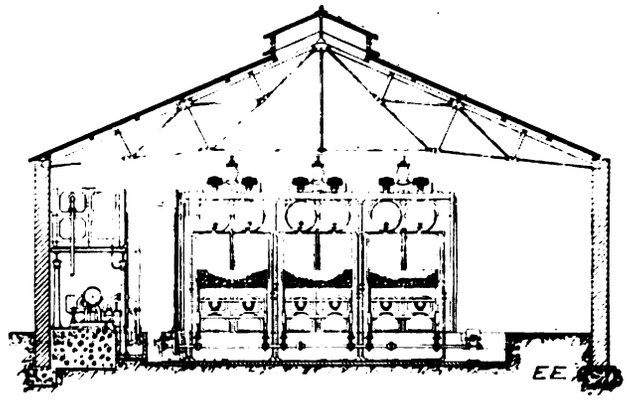

Fig. 15.—Front View of Boilers.

stationary bars, where they form up and maintain a bank, which acts as a bridge, closing the far end of the ashpit, and on which the combustion of the precipitated fuel is in due course completed. The firebars are about 3½ft. in length, with a perforated dead-plate 12in. long; thus practically the extent of grate is 4½ft. The smoke consumption is effected by baffling down by means of brick arches the gases driven off the fuel while coking is taking place on dead-plate, and causing these gases to pass over the more incandescent fire at the end of the bars. Means are also provided for ensuring a sufficiency of air for proper combustion. The supply of fuel and the travel of the firebars are regulated with facility, independently of each other, by means of a simple mechanical combination, for which motive power is required. The travel of the bars may be adjusted to any length, from a state of rest to a maximum of 4in. The alternate fire-bars are drawn towards the front of the furnace, and then all the firebars travel inward together. The motion is derived from an underground driving-shaft, upon which are keyed driving eccentrics, which act upon ratchet wheels and pawls, and give the necessary movement to stoker shafts, and by means of cams on these shafts the horizontal movements on firebars and plungers are effected. The speed of this motion can be regulated to from 30 to 120 turns of the shaft per hour. The furnace can, when required, be fed by hand through a doorway between the two pushing rams. The whole of the shafting working these Vicars's stokers is driven by an electric motor of the

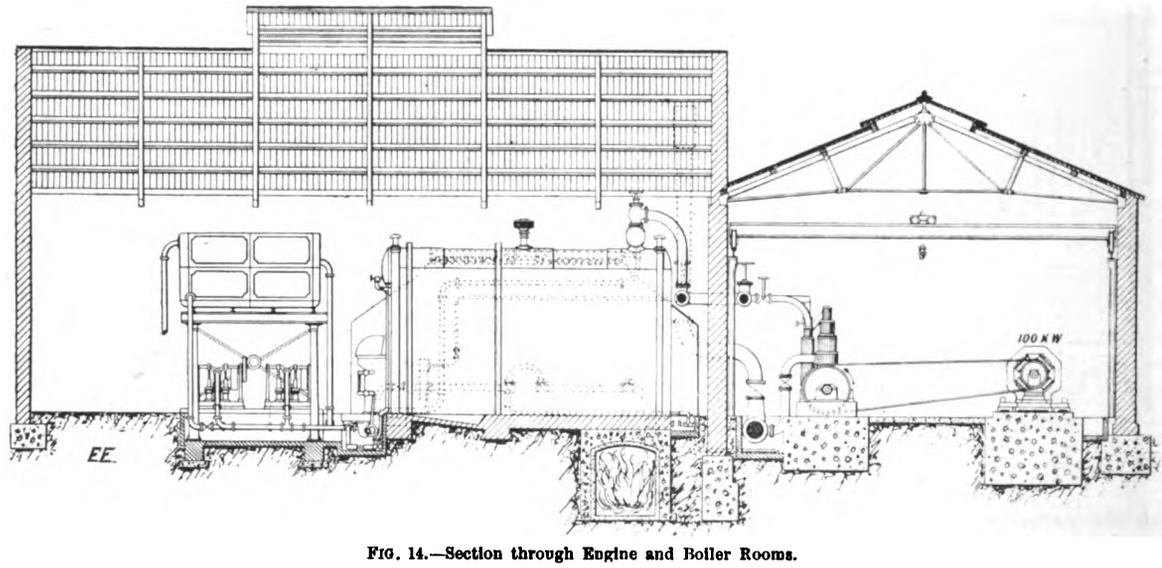

Fig. 14.—Section through Engine and Boiler Rooms.

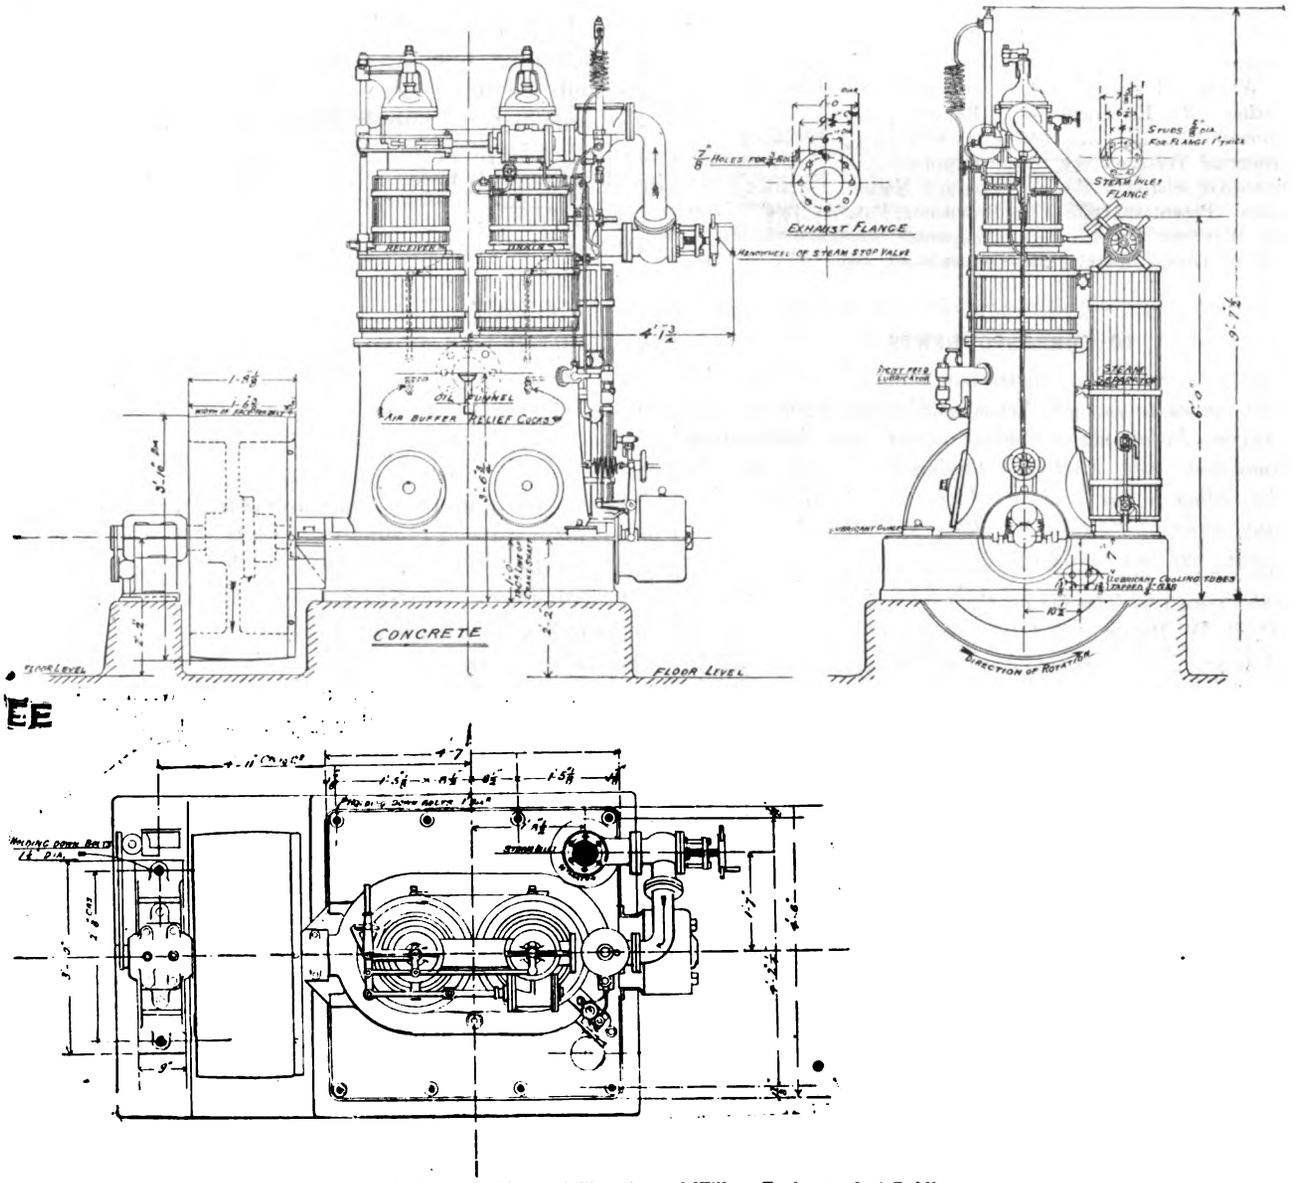
Digitized by Google

General Electric Company's make. The motor is, in fact, one of the type used for driving electric cars, but shunt wound. The dustproof case prevents the coal-dust from injuring the working parts. This electric motor is placed in a small pit at the right-hand side of the battery of boilers, and therefore cannot be seen in Fig. 10, which, however, shows the front of two boilers with the mechanical stokers in position. In the foreground of this illustration are shown the electrically-driven feed pumps. These have been manufactured by Messrs. Daniel Adamson and Co., and are driven by General Electric Company's motors. As will be seen in Fig. 11, the pumps are of the three-throw type, and the motors drive the crank axle through double-reduction spur gearing. These pumps are connected with a duplicate set of feed pipes, and separate feed arrangements

A straight line of cast-iron pipes is led to the condenser. This latter plant has been supplied by Messrs. Browett, Lindley, and Co., and is designed to be capable of condensing 19,000lb. of steam per hour. The tube surface of the condensers is 1,200 square feet. The plant consists of a pair of vertical single-acting air and circulating pumps, mounted on a cast-iron base-plate. The buckets are worked by links attached to an overhead beam mounted on a rocking shaft, which is supported on bearings between the pumps. The rocking shaft has at one end a lever, which is connected by means of a connecting rod to a crank-pin, mounted on a wheel on the engine shaft. The surface condenser is placed alongside the pumping plant, and has branches connected to the air and circulating pumps, and also a branch for connection to the exhaust



FIGS. 16 AND 17.—Plan and Elevations of Willans Engine used at Dublin.

are also provided by means of injectors. The feed water is heated by means of a Green's economiser, the scrapers for which are also driven by the same motor that works the mechanical stokers. The chimney shaft is 110ft. high, and 6ft. in diameter inside. The exterior is octagonal in shape. The chimney is lined 30ft. up with firebricks, and communicates with the furnaces by two 30in. flues.

STEAM AND EXHAUST PIPES.

The steam-piping is designed on the ring system, and has a liberal supply of Hopkinson's valves to isolate any defect that may arise, so that continuous working may be ensured. The main ring is constructed of mild-steel pipes, 8in. in diameter. The bends to the engine are made of copper. The arrangement of the exhaust-pipes can be seen in Fig. 12, which shows the plan of the station.

steam main, and a branch for circulating water discharge. The engine is of the vertical tandem compound E. L. type, with a 4in. crankshaft, and is fitted with an "Acme" governor. The following are a few of the dimensions of this plant: size of steam-cylinders, 7½in. and 12in. diameter by 10in. stroke of piston; air-pump cylinder, 12in. diameter by 12in. stroke of bucket; circulating pump, 24in. diameter by 12in. stroke of bucket (both these pump barrels are removable); the diameter of the exhaust branch is 16in.; the diameter of circulating water suction and discharge, 10in.; and that of the air-pump discharge, 6in. The 8in. suction buckets are of gunmetal, having a large area through for the passage of water and air, and are fitted with grey rubber valves and brass guards.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

TWO SIDES.

It is not often that the Board of Trade say "no" to the request of a local authority applying for a provisional order, but this has occurred at Newington. An examination into the whole matter, however, will clear away surprise. In the first place, a provisional order is already in existence for a part of the district. In the second place, the decision of the Vestry was arrived at by the casting vote of the chairman. We are writing from recollection on that point, and are open to correction. In the third place, great opposition was manifested against the scheme when the enquiry of the Board of Trade was held. Neither of these circumstances, considered separately, might have been considered adequate to condemn the scheme, but the combination was fatal. Although we have been strenuous advocates for the local authority to supply artificial light, we cannot complain of the action of the Board of Trade in its decision as regards Newington. The local authority is the proper authority to do the work, but if the local authority does not take advantage of its opportunity, it ought not to be allowed to stand in the way of private enterprise. The waiting policy is suicidal. We shall all be dead and forgotten if we wait to act while certain people make up their minds. The time of Newington was before the first provisional order—that being granted, we take it, with the consent of the authority, support should have been given to the holders of the provisional order, instead of an attempt being made to filch that which had been granted. There are usually at least three parties to be considered in any attempt to light a district electrically. First we have those interested in gas, who, from a business point of view, can hardly be deemed to look upon the question with favour. Their opinions must be largely discounted. On the other hand, we have those interested in electricity, and their opinions are no less rabid and one-sided than those above named. A third party is unconnected with either gas or electricity, and ought to listen to both with respect and judge without bias. Unfortunately, the third party as a rule is conspicuous in keeping away from all meetings and proceedings when its opinion should have the greatest weight. "Oh, let them fight it out," is the cry, and so the result is too often a battle-royal between two interested parties. We have not cared to examine too closely into the local politics of Newington, but it is natural to assume that the chairman's vote was given because the interested parties were equally balanced and disinterested parties took little part in the matter. It has always been assumed that if a local authority took up the question the Board of Trade would decide in its favour, but we have perhaps recorded the exception which proves the general correctness of the assumption. Since humanity began to write, an axiom has existed that the important sentences of a lady's letter will be found in the postscript. Perhaps our real text may be similarly indicated at the close of this short article. How is it that men engaged in the electrical industry are so ready to cut one another's throats? There is scarcely a local authority, or a company, or a firm,

Digitized by Google

or an individual commencing to look into the matter of electric lighting but is pestered with the attentions of men engaged by some other person than the one employed to look into the matter, these attentions being directed towards displacing the man in possession in favour of the nominee or master of the person who is so officious in paying attentions where they are not only not wanted, but which again and again work incalculable harm. The moral may receive point from an old tale. If we remember rightly, Portsmouth once had a consulting engineer, and that consulting engineer and his designs were superseded partly, if not wholly, because another engineer, unsolicited, went to the chairman of the committee and condemned the practically accepted designs. This was stated publicly at the opening of the station. We maintain that interfering action of this character is unprofessional, and has done and is doing harm. The petty squabbles that characterise many of the meetings of the authorities can be directly traced to the interference of members of the industry who are simply trying to oust the man in possession in order to get in themselves or to assist some member of their clique. This may be sharp practice, but it is not business.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

May 16.—Visit to the Southern Extension Works of the Overhead Railway.

INSTITUTION OF ELECTRICAL ENGINEERS, May 14.

At last night's meeting of the Institution the following candidates were balloted for:

Associates.—A. S. Anderson, the Northern Electric Supply Company, Cults Generating Station, Aberdeenshire; Frederick Ernest Andrews, "Foxholme," Loughborough, Leicestershire; R. B. Johnson, 108, Elgin-crescent, Notting Hill, W.; Alfred J. Hollington, 28, Bush-lane, Cannon street, E.C.: James Patchett, Wellington, Shropshire; Frederick S. Pilling, Electric Light Station, Dagger-lane, Hull; Thomas Scott, 18A, Eldon-street, London, E.C.; John Henry Whittaker, 53, High-street, Dudley.

Student.—William Collins, "Oakville," Overcliffe, Gravesend.

DUBLIN ELECTRIC TRAMWAYS.

(Concluded from page 545.)

The surface condenser casing is of cast iron, fitted with covers at each end, and arranged with air-chamber pockets, and dividing ribs, to produce a sinuous flow of water through the condensing tubes and avoid shock. The tube plates are of Delta or Muntz metal, 1¼in. thick, and secured to flanges in the casing by means of brass screws. The tubes are of seamless drawn brass, ¾in. diameter by 5ft. long, and are fastened in the tube plates by means of screwed ferrules and tape packing. As has been mentioned above, the water for condensing will be taken from the River Dodder. An elevation of the plant is shown in Fig. 13, while Fig. 14 shows a complete section of the boiler and engine room giving the relative vertical positions of the exhaust and steam pipes. Fig. 15 shows the front elevation of the boilers with the mechanical stokers.

Engines.

Messrs. Willans and Robinson have supplied the engines for this important station. They consist of four engines of the H H compound type, and are designed to run at 380 revolutions a minute. The ordinary continuous load is 170 b.h.p., but the engines are capable of delivering 200 b.h.p. on occasion. They are fitted with variable expansion gear, which has been described before in our columns, the gear being automatically controlled by the governor. The diameter of the high-pressure cylinders is 12in. and that of the low-pressure ones 17in. with an 8in. stroke. Each engine is provided with a 3ft. 10in. flywheel pulley arranged with an outer bearing to prevent strain at the main bearing of the engine. These engines (shown in Figs. 16 and 17) drive the dynamos by means of 16in. belts.

Dynamos.

The dynamos and alternators have been supplied by the British Thomson-Houston Company. There are two direct-current railway generators with four poles, each capable of giving 100 kilowatts continuously or 120 kilowatts on emergency without sparking. These dynamos are fitted with carbon brushes and supply the current to the trolley feeders at 500 volts. These machines are compound wound, and are provided with equalising switches to connect across the compound winding when the two machines are working in parallel. These continuous-current dynamos are on the foreground in the general view of the engine-room, shown in Fig. 18. The other two engines are used to drive two 120-kilowatt, six-pole, three-phase alternators, working at a frequency of 30 complete periods per second. These machines have been manufactured at Messrs. Armstrong, Mitchell, and Co.'s works at Newcastle-on-Tyne, to Mr. H. F. Parshall's design. The low frequency is advantageous when the machines are to be used for transmission of power only, as in this case. These alternators are remarkable for the compact nature of their design, which is such as to give a high degree of mechanical strength and durability. The armature coils are buried in a laminated iron core after the usual practice of the company. The alternators are connected to the alternating-current motors at Blackrock and Dalkey sub-stations, as indicated by the general diagram of the line (Fig. 19).

Accumulators.

The battery of accumulators erected at Ballsbridge consists of 55 Epstein cells, of type R 11, each cell being composed of 11 electrodes (five positives and six negatives) contained in glass boxes. The battery was first charged last February, and is installed for the purpose of lighting the generating station. The capacity of the R 11 Epstein cells, at a rate of discharge of 65 amperes, is 10 hours, but they can be charged and discharged at very high rates without detriment to the plates, and the cells mentioned could upon emergency be discharged at 350 amperes during about one hour with perfect safety. This battery is charged by means of the continuous-current transformer shown in Fig. 20. It may be added that the gentlemen who appear in this illustration are Mr. Clifton Robinson, Mr. H. F. Parshall, and Mr. Robinson, jun. The transformer consists

Digitized by Google

of a 30-kilowatt 500-volt motor, which is driven by the main dynamos and is directly coupled to a 125-volt continuous-current dynamo, which can be worked at a higher voltage for charging the accumulators. Besides being used for lighting the station, the accumulators in connection with the C.C. transformer are very handy for testing purposes. In one instance the high-pressure feeder was tested at an abnormally high voltage by this means. The batteries first supplied current at about 500 volts to the trolley wire, and this at the Blackrock sub-station was transformed up to 5,000 volts alternating.

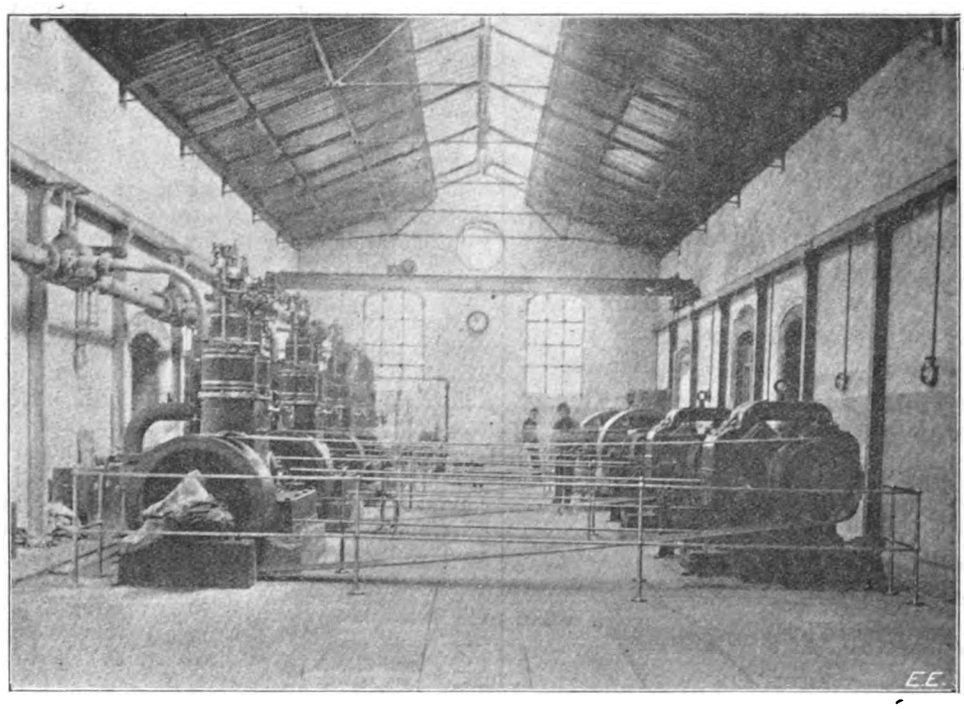

FIG. 18.—General View of Engine-Room.

SWITCHBOARDS.

The switchboard at the central station is not shown in any view, but it is not unlike that of the switchboard at the Blackrock sub-station, shown in Fig. 21. The diagram of the connections at Blackrock on this board (Fig. 22) will also help to make the arrangements clear. In this diagram A denotes a three-pole switch having a capacity of 50 amperes; B a rheostat of the F.F. 52 type for the motor fields, including a pilot lamp and the resistances required; C a small switch for use in connection with the lamps, for indicating phase difference; D a synchronising transformer having a transforming ratio of 25 to 1. At E are shown rheostats for the fields of the direct-current generators, while F is the starting rheostat for the same. G shows automatic railway cut-outs used to isolate the line in case of short-circuit; these are seen at the upper right-hand corner of the board (Fig. 21). H denotes a lightning arrester, and I a single-pole fuse. J J are high-tension alternating-current ammeters of the Nalder type, while K is a low-tension direct-current ammeter. V denotes a voltmeter, also for use with alternating currents, and N a Ferranti oil-break fuse, while synchronising lamps are indicated by the letter L. The alternators will usually be worked in parallel, but arrangements can be made for working them on individual lines, as there are two distinct triple concentric feeders between Ballsbridge and the Blackrock sub-station. The low-tension switchboard, shown in Fig. 20, needs no description; the small switches seen on it simply control the individual lighting circuits in the central station.

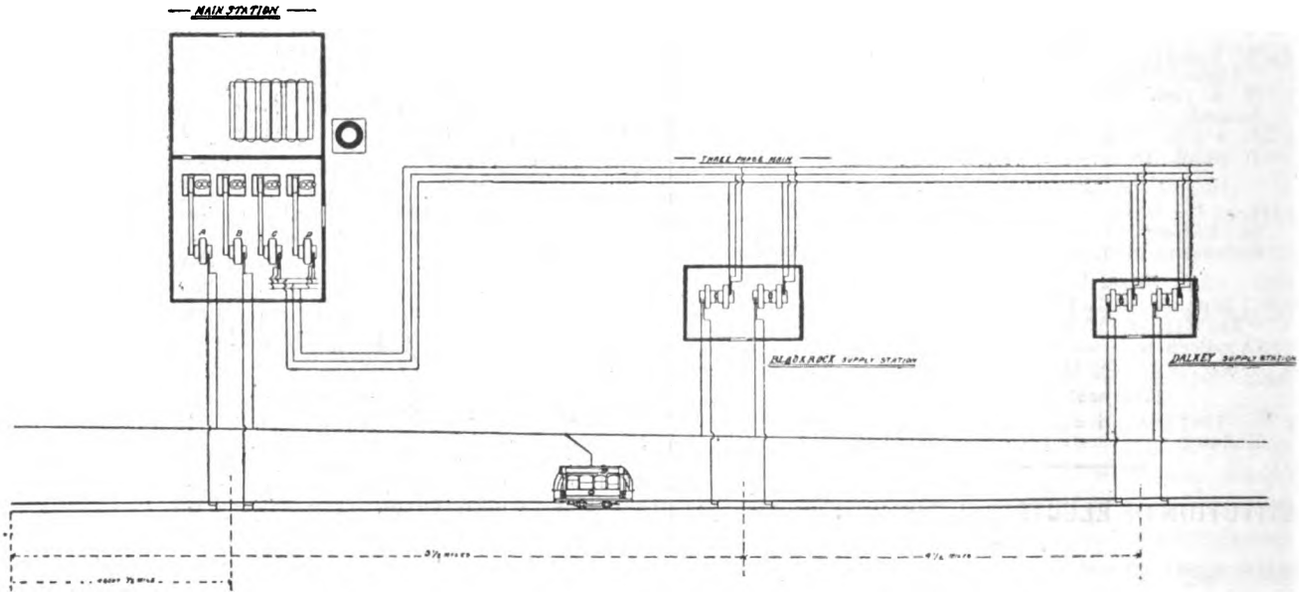

FIG. 19.—Diagram of the Connections of the Whole Line.

HIGH-TENSION FEEDERS.

The whole of the high-tension feeder mains were supplied by the British Insulated Wire Company (see Fig. 23). They are triple-concentric cables for tri-phase current, each

Digitized by Google

conductor having a sectional area of ·05 square inch, and being insulated with their patent paper for working pressures up to 3,500 volts. They are lead-covered, and armoured over all. The total quantity of this cable supplied was 11½ miles, and the whole of it was tested length by length before leaving the factory with a pressure of 12,000 volts for 15 minutes both between the outer and inner and between the outer conductor and the earthed sheathing. Two of these cables are laid between Blackrock and Ballsbridge, and one between Blackrock and Dalkey. The cables are laid in a trench by the side of the footpath, and have been tested up to 5,000 volts in position.

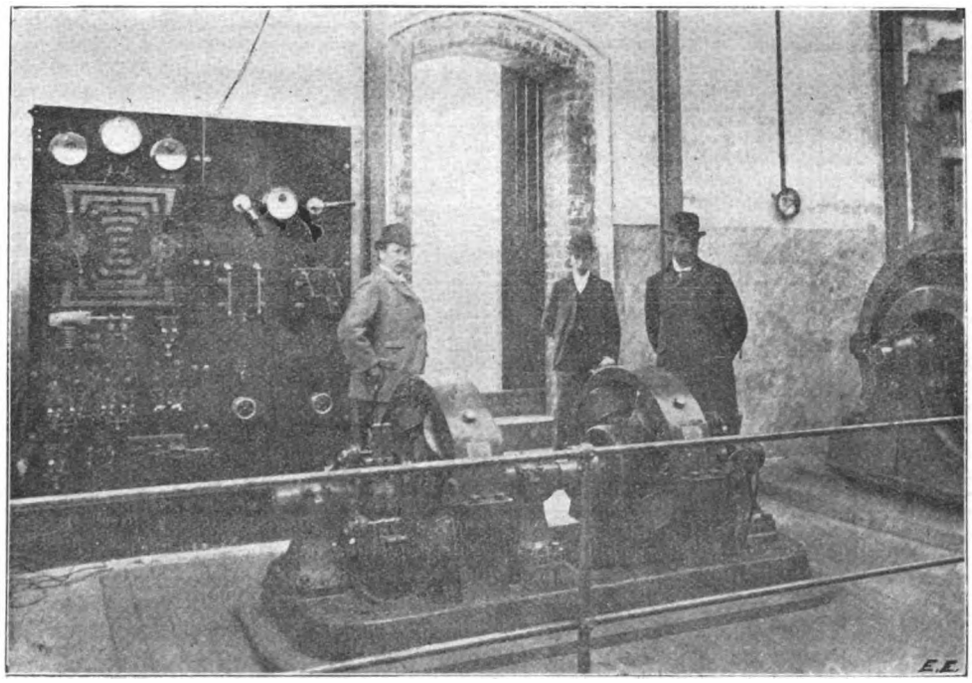

FIG. 20.—Direct-Current Transformer.

The direct-current generator is first connected on to the main 500-volt feeder and, by means of the starting resistance and field rheostat, is brought gradually up to its normal speed. The field of the alternating-current motor is then excited, and when the synchronising gear indicates that the correct phase has been attained the main switch is closed, which connects the motor to the high-tension feeder. The load can then be taken by the alternate-current machinery, and current supplied to the lines as required by the cars. The particulars of the switchboard at this station have been given above. At Dalkey a similar plant has been installed, except that the direct-

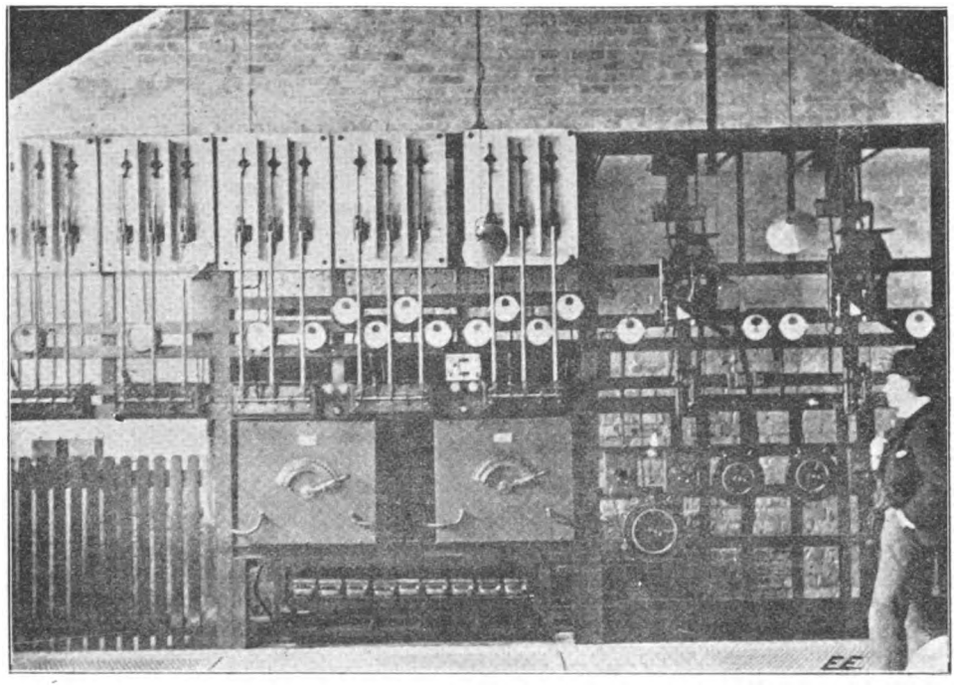

FIG. 21.—Switchboard at Blackrock.

SUB-STATIONS.

A full view of the above-mentioned station at Blackrock is shown in Fig. 24. The two transformers consist of two 60-kilowatt direct-current railway generators, coupled to two three-phase synchronous alternate-current motors working at 2,000 volts normally. The coupling between the two machines is effected by means of two pins projecting from one coupling, and fitting into holes in the other half, which are bushed with indiarubber. In this way any slight want of alignment is compensated for, and the machines have given no trouble in this respect. The method of starting one of these transformers is as follows:

Digitized by Google

current generators are at present somewhat smaller. This arrangement is found to work most satisfactorily in practice.

Board of Trade Inspection.

The line was formally inspected by the Board of Trade on Thursday, May 7, and in spite of the stringent requirements of the Board as regards the conductivity of the return circuit, etc., everything was found satisfactory. A few alterations in the levels in the roads on either side of the track were ordered, and subject to these full permission for the opening of the line for regular traffic was promised.

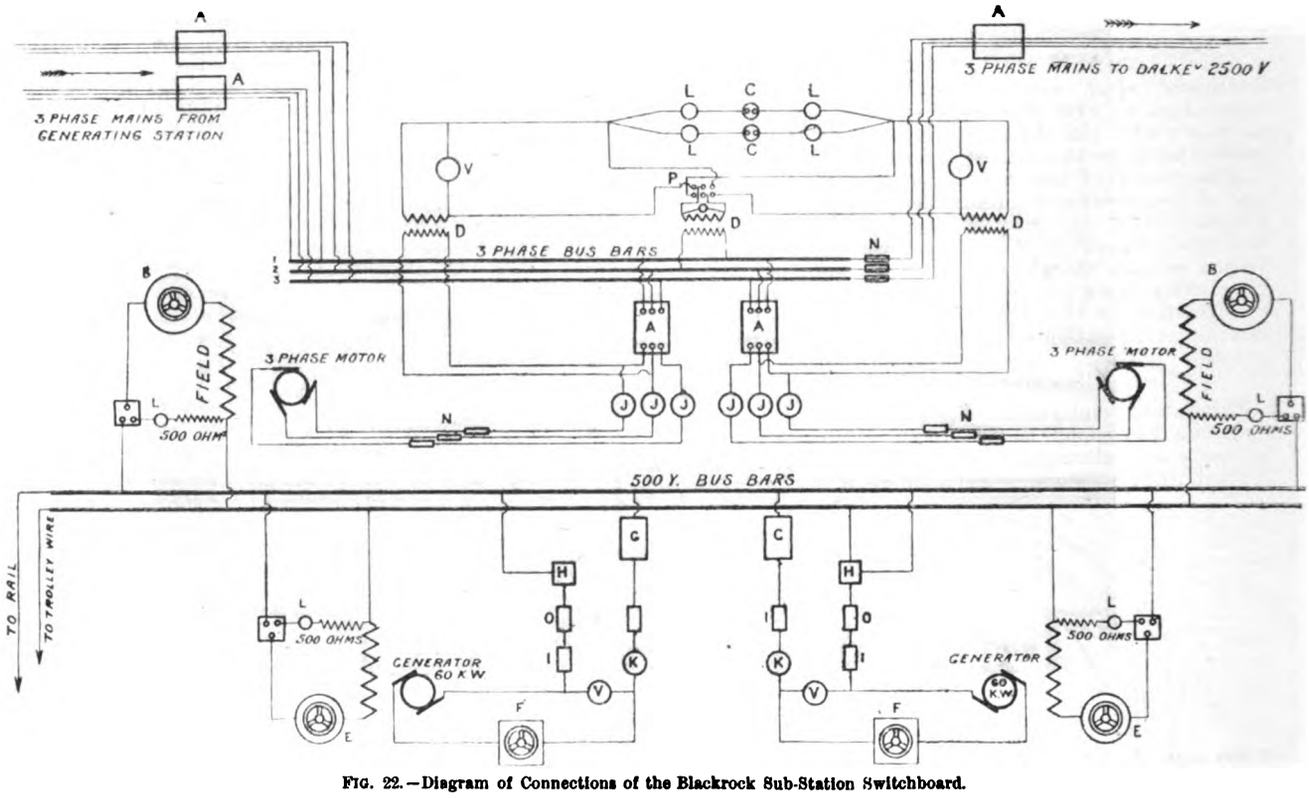

Fig. 22.—Diagram of Connections of the Blackrock Sub-Station Switchboard.

The company promised to do all they could to prevent any inconvenience.

We are able to give the above full particulars through the courtesy of Mr. Clifton Robinson and the British Thomson-Houston Company, as well as the various con-

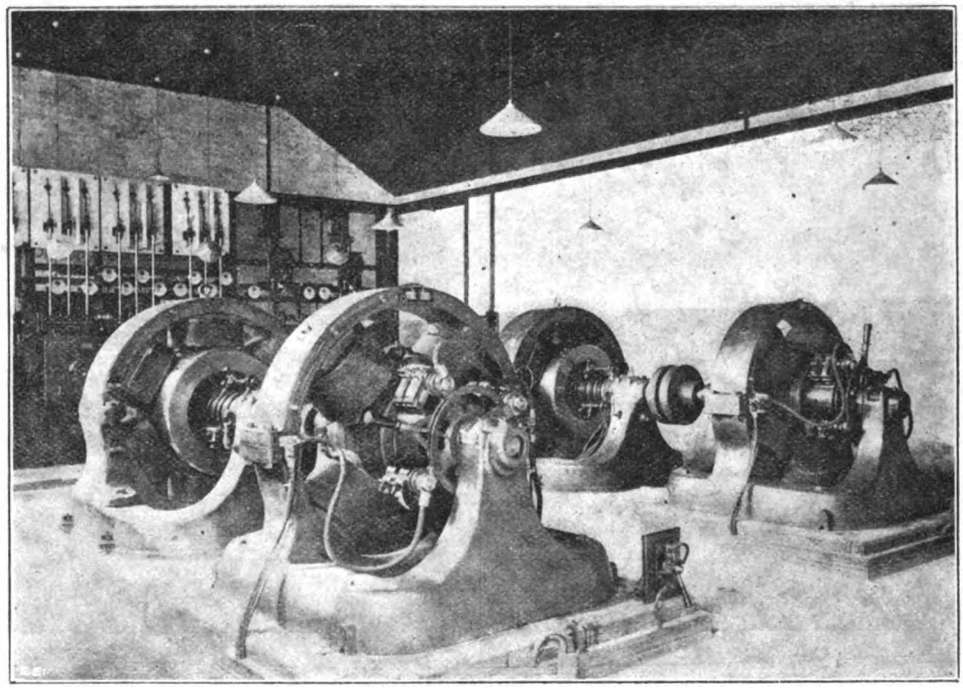

Fig. 24.—Blackrock Sub-Station, with Alternating-to-Direct-Current Transformers in the foreground.

Major Cardew made a careful inspection of the 16 miles of track, and found the electrical leakage to be only about one-sixth of the maximum allowed by the Board of Trade requirements. In George's-street, in Kingstown, several gentlemen boarded the car and formally complained that the double track would be an injury to their business, as it would interfere with the loading and unloading of their vans. The inspector said they had a right to be indignant with the Town Commissioners, but not with the company, who had obeyed the instructions given them by the local authority, which had involved an extra expenditure of £7,000.

We are able to give the above full particulars through the courtesy of Mr. Clifton Robinson and the British Thomson-Houston Company, as well as the various contractors who have had the work in hand. We wish Mr. Robinson every success in the running of this line, and trust that the excellent character of the work will assist him in obtaining the necessary powers for making the extensions into the heart of Dublin.

EXPERIMENTAL TESTS ON THE INFLUENCE OF THE SHAPE OF THE APPLIED POTENTIAL DIFFERENCE WAVE ON THE IRON LOSSES OF TRANSFORMERS.*

BY STANLEY BEETON, C. PERCY TAYLOR (STUDENTS), AND JAMES MARK BARR.

Introductory.

At the conclusion of some articles on "Wave-Form Synthesis," which were published in June, 1895, we mentioned that we were then engaged in testing the iron losses in transformers with the aid of the method we had devised for easily altering the shape of the applied potential difference wave

This question of iron losses has naturally been regarded as one of considerable importance by electrical engineers, since the success of every system of alternate-current supply depends to a great extent on the all-day efficiency of transformers. Hence we have thought that an account of some fairly complete experiments on this subject might be worthy of the consideration of this Institution. These experiments were carried out at the Central Technical College during May, June, and July, 1895.

Description of Apparatus.

The method employed in our transformer tests was that of obtaining the complete curves of potential difference and current by means of an electrometer and Joubert contact-maker. This method, while being simple and accurate, is absolutely complete.

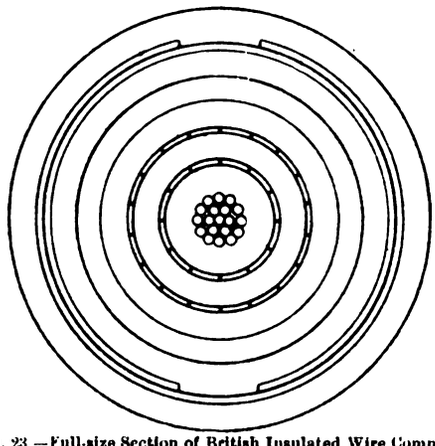

Fig. 23.—Full-size Section of British Insulated Wire Company's Triple Concentric Cable used at Dublin.

Any results required can be calculated from the two curves taken. The P.D. was kept constant by means of an Ayrton and Mather electrostatic voltmeter. Thus, we used only electrostatic instruments which required no sort of correction, such as is necessary when wattmeters and dynamometers are employed. The method we employed for varying the shape of the P.D. wave impressed on the transformer consisted in throwing into the circuit during similar parts of each half-wave a resistance or capacity by means of an apparatus which we have called the "injector." It is indicated in the accompanying diagram (Fig. 1), which also shows the details of the remainder of the apparatus used by us in testing the iron losses in the transformer.

The "Injector."—The arrangement which we have previously called the "injector" is shown diagrammatically at J. It consisted of two brushes, b_1 b_2, bearing on a commutator keyed to the shaft of the alternator. To these brushes was connected a resistance or capacity, as the case might be. We used a Ferranti alternator giving eight complete periods per revolution, and, in order that we could throw into the circuit any desired resistance or capacity during certain similar parts of each half-wave, the commutator was made with 16 segments. These segments—completely insulated from the machine and from one another—had no connections brought to them whatever; they were merely used to periodically short-circuit the two brushes, b_1 b_2. The position of the brush b_2 determined the epoch, or the instant at which the resistance or capacity was thrown into the circuit, while the distance between b_1 and b_2 determined the interval, or the duration of the effect for any given speed of the alternator. To the other end of the alternator shaft was fixed the usual form of Joubert rotating contact-maker. The movable brush, C, and fixed graduated scale, used for taking the wave-forms, were also employed by us to fix the positions of the "injector" brushes in the following manner:

Method of Setting the Injector Brushes.—The normal P.D. wave was first obtained in the ordinary manner, and by this means we really calibrated the fixed scale of the contact-maker; that is to say, we found positions of the brush C corresponding with certain points in the wave of P.D., thus imparting a definite meaning to each point in the scale. Having decided over which part of the normal P.D. wave the injection was to take place, we found the points corresponding with this interval on the fixed scale of the contact-maker. Let these points be a and d. The brush C was fixed with the pointer at a, and the alternator shaft turned until the metal web of the contact disc came under the brush (this is the position indicated in Fig. 1), and the trailing injector brush, b_2, was then adjusted till it was about to leave one of the segments. We next moved on the brush C to the point d and turned the shaft of the dynamo until contact between the brush and the metal web was again restored. With the armature in this position the brush b_1 was set so that it was just coming on to the next segment behind the one which b_2 had been adjusted to leave. It is evident, therefore, that during the interval in which the armature moves from the position a to the position d, the resistance or capacity inserted between b_1 and b_2 would be in the circuit, and that during the remainder of the half-wave it would be short-circuited.

Transformer Details.—Our tests were carried out on a Mordey transformer designed for an output of three kilowatts. The transformer was wound with three coils, two consisting each of 12 turns, and intended to be used with a pressure of 50 volts, while the third or fine-wire coil was wound for a pressure of 2,000 volts. This latter and one of the former were left on open circuit throughout these experiments, and the other coil was used by us as the magnetising coil, taking about three amperes at a frequency of 100 ∼. Hence, as the resistance of

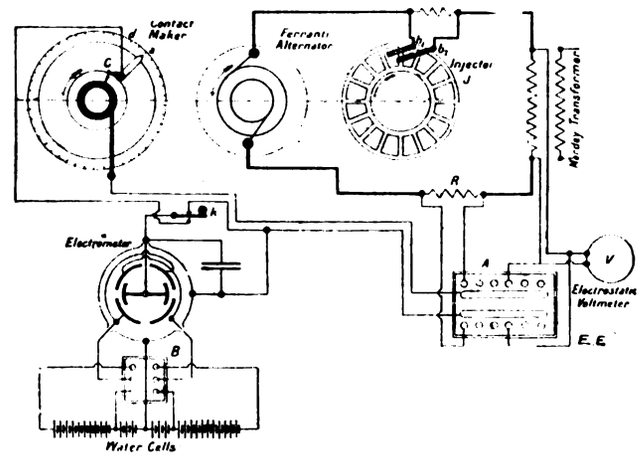

Fig. 1.

this coil was only 0·016 ohm, the drop in pressure due to it was negligible.

Electrometer Connections.—The instrument used for taking our waves was an Ayrton and Mather quarter-cylinder reflecting electrometer, connected up in series with the Joubert contact-maker. In parallel with the electrometer we had a small condenser, which was short-circuited by the key, K, after every reading. A number of water cells were used to maintain a permanent P.D. between the opposite pairs of quarter cylinders, and the P.D. to be measured was set up between the needle and the case. This method, as explained in our above-mentioned article, has the advantage of making the deflection directly proportional to the P.D. to be measured, even when the auxiliary P.D. required in the heterostatic use of an electrometer is quite small. The only readings used in working out the tests were those taken with the electrometer, for this instrument was also employed to measure the P.D. between the ends of a non-inductive resistance, R, placed in series with the transformer, and so to indirectly measure the current flowing through the latter. The electrometer was calibrated before, and in almost all cases after, every test with a set of 70 standard Clark cells. In order to facilitate taking the instantaneous values of both P.D. and current in quick succession, two change-over switches were used at A and B. A consisted of a solid block of paraffin wax, in which were cut two long slots and two rows of small holes, all of which were filled with mercury. The electrometer and contact-maker were directly connected with the two slots, while to the small holes were led wires from the terminals of the transformer and the non-inductive resistance, R, or from any points in the circuit between which we wished to find the instantaneous value of P.D. As a matter of fact, the terminals of the "injector" were also connected with a pair of holes in the change-over switch, A; but these wires are not shown in the diagram, as the graph obtainable at these points was not always taken, and it did not form an essential part of the transformer test. The value of the non-inductive resistance was 4·15 ohms, so that the maximum reading for obtaining the current-wave was about 16 volts, whereas the maximum ordinate of some of our P.D. curves was as high as

* Abstract of paper read before the Institution of Electrical Engineers, May 14.

Digitized by Google

100 volts. In order, therefore, to use the full range of the electrometer in each case, it was necessary to change the potential to which the quarter-cylinders were charged; hence for the P.D. wave we used six cells between the opposite pairs of quarter-cylinders, and for the current-wave 30 cells, the middle of either set being connected with the case. This alteration was effected by means of the change-over switch, B. An Ayrton and Mather electrostatic voltmeter, V, was used to keep the R.M.S. volts at the terminals of the transformer constant during each test.

Speed of the Alternator.—The speed of the alternator, which could be adjusted by means of coned pulleys, was kept constant at 750 revolutions per minute, thus giving a frequency of 100 ⌣⌢. No electrometer reading was taken unless the speed, as shown by a Rungs pneumatic speed indicator, was exactly right. The indicator was checked several times by a revolution counter and found perfectly accurate.

Advantages of Open Secondary Tests.—Since it is now generally admitted that, with the exception of a slight drop due to leakage at high loads, the total iron losses in a transformer are constant at all loads for the same frequency, we made all our tests with open secondary circuit. This method of attacking the subject offers great advantages, because errors caused by the variations of temperature in the iron core and the non-inductive resistance, R, due to the use of different currents, are not introduced into our experiments. In addition to this, it will be seen that the working out of our results is somewhat simplified, especially with respect to the determination of the maximum induction. It is in the determination of the iron loss, however, that the method possesses its chief advantages, for we can measure this loss directly, and not as the difference of two much larger quantities. By this means we have been able to find the iron loss accurately to within ½ per cent., which would have been quite impossible with a load on the secondary.

Discussion of Curves.

All the curves of P.D. and current given in the figures have been obtained by taking the means of the homologous readings on each half-wave. The mean wave thus determined was never found to differ appreciably in any way from the positive or negative half-wave. Each wave was drawn as the observations were made, so that, when the exact contour of the wave appeared doubtful, more readings at points intermediate between those already observed could be at once taken and plotted; hence a large number of observations were made on every wave, sometimes as many as 48 points being taken. The normal P.D. wave of the Ferranti alternator (Fig. 2) is seen to be very nearly a sine curve, while the current-wave possesses the characteristic deformation always observed when a transformer is working light.

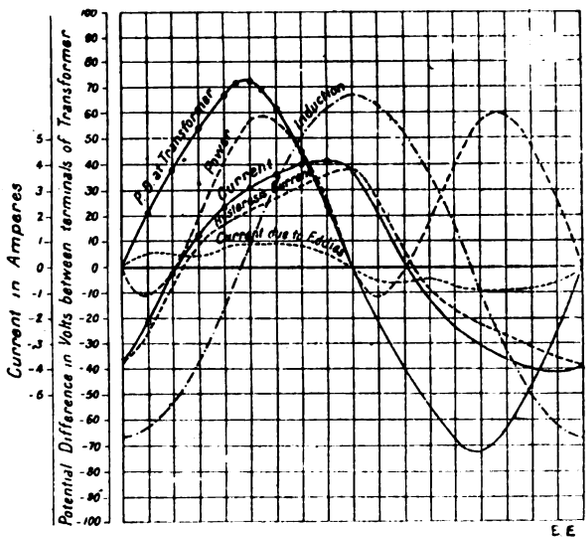

Fig. 2.

Induction Waves.—The induction wave must be found by integrating the curve of back E.M.F. Now in our case the latter is practically identical with the applied P.D. wave, since the drop in pressure due to the resistance of the magnetising coil is negligible. It is interesting to note how smooth the outlines of the induction curves are, even when derived from very distorted waves of potential difference. We have, therefore, to integrate the P.D. wave; but to do this we require some starting point, and this must first be found. When the ordinate which divides the half-wave of P.D. into two parts of equal area is known, this presents no difficulty, as the induction must be zero at the point where this ordinate cuts the axis of time. When, however, as is more often the case, we do not know this ordinate, then the above relation will not help us; but there is another relation which is true in every case—viz., that the induction must be a maximum when the P.D. is zero. It is evident, on reference to Fig. 3, that, according to this relation, the induction must pass from a negative to a positive maximum, or *vice versâ*, during the half period of the P.D. wave. Since the induction wave is the integral of the P.D. curve, it will also be evident from Fig. 3 that the area of the semi-wave of P.D., multiplied by the required constant, will give twice the maximum induction. (This constant must contain the number of turns in the magnetising coil and the cross-section of the iron core.) Thus in every case we can get a starting point for the induction curve by setting up the maximum induction at the point where the P.D. is zero.

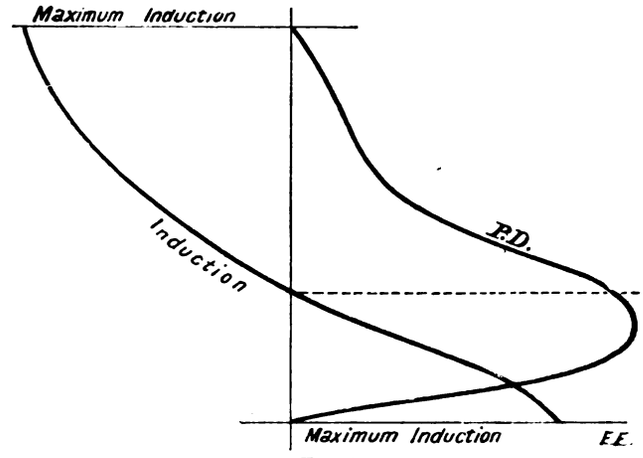

Fig. 3.

The wave is then drawn by integrating the P.D. curve in steps from this point, and subtracting the inductions thus obtained from the maximum value. This direct relation between the maximum induction and the area of the P.D. wave is of the greatest importance, for it is evident then that the amount of hysteresis loss for different shapes of applied P.D. waves will depend only on the areas of these waves.

(To be continued.)

THE ELECTRIC LIGHTING OF SURBITON.

The District Council have recently printed and circulated the report of Dr. Hopkinson on the tenders they had received for laying down an electrical installation. After comparing the conditions of Surbiton with those of Whitehaven, Dr. Hopkinson proceeds to discuss the relative merits of the high and low tension systems of electrical distribution, and concludes: In the case of Surbiton the maximum distance to which you would have to go is less than a mile, and I should therefore have not the least hesitation in recommending the direct-current low-tension system with a maximum difference of pressure of 400 volts or thereabouts, giving 200 volts on the lamps, and that the streets throughout the district, with the exception of, perhaps, of some of the new extreme outlying parts, be lighted from the same source of supply as the private lights. The street-lighting circuits should be all taken in to the generating station independently of those for private lighting, as in this way a considerable economy will be effected, owing to the facility with which the lights can be lighted and extinguished. The number of street lights to which a supply of current would have to be carried would be about 480, and of these a considerable number have at the present time multiple burners of considerable power. To replace the whole of these lights with incandescent lights of somewhat greater power would require about 60 i.h.p. But it is probable that a larger number of lights of increased power might at a future time be required, and I should therefore provide engines and dynamos of 100 i.h.p. each, and use the excess of current generated (if any) for the purpose of aiding in the charging of the accumulators.

Surbiton is fortunate in having a vacant space right in the centre of the district suitable for the generating station. This is upon the land to the south side of the railway, and slightly to the west of the railway station.

The equipment of the generating station would be as follows: four Babcock and Wilcox boilers, each capable of generating steam for 100 i h.p.; an economiser; four sets of Willans engines (with dynamos), each capable of indicating 100 h.p.; Ledwards evaporative condensers; the suitable switches and instruments, and a battery of equal power to about one of the dynamos. Each engine would be competent to supply current for 1,000 incandescent lamps of 16 c.p. each, so that if one engine be considered as spare, you would have, including the battery, a plant capable of supplying 4 000 lights.

We will now consider the capital outlay which the provision of this plant and the conductors will involve. This is shown on the accompanying Schedule I., in which it will be seen that the total cost amounts to £22 000, which involves an annual charge for interest and sinking fund of about £1,200, which would have to be paid whether there were private consumers or no. The actual

Digitized by Google

cost of running the station would, of course, depend in part upon the amount of current to be generated. Assuming that the maximum demand in the evening was sufficient to occupy three engines, three boilers, and the accumulators, I should estimate that the whole running charges would be less than £1,800, making the annual outgoings less than £3,000 Consider now the other side. You have to begin with about £1,800, the present cost of street-lighting with gas. This would be replaced by better lighting which we assume is done at the same cost by electricity. You have available power to light in addition to this 3,000 16 c.p. to 3,500 16-c.p. incandescent lamps on private consumers' premises. This would imply that a considerably larger number were wired. General experience has also shown that a 16-c.p. lamp will bring in a revenue of from 15s. to 20s., so that if the plant were completely occupied at full rates of charges a revenue of at least £4,500 might be anticipated from private consumers. Against this will of course have to be set the charges for service mains and meters, which would increase the capital outlay and consequent charges for interest and sinking fund to a small extent. This will serve to show that in the event of the light being largely taken up by private consumers, the possible profit to the Council would be considerable. Probably, however, a less number of lamps and a lower return per lamp might be expected, but the demand would be poor indeed if £1,200 a year could not be speedily secured from private customers, and it must further be remembered that if the demand for current were diminished, the cost of running would also be diminished.

It will be more convenient to consider the matter from another point of view. After crediting the account with the present cost of lighting the streets by gas, there would remain less than £1 200 per annum to be met by the receipts from private consumers. How many lamps would it be necessary to instal to secure such a revenue? At 15s per lamp, 1,600 would suffice. This number is less than you may with confidence anticipate. The fact of there being at once a very large consumer in the public lighting ensures that in the case of Surbiton the undertaking should be commercially successful from the very commencement.

Let us, however, consider what the cost of lighting the streets without the addition of any private lighting would be. Schedule II. shows an estimate of ample power, ample buildings, and ample conductors for the supply of the 480 lights in the town, with a margin for additional lights and a spare engine and boiler. No accumulators are required, as the light need not be supplied in the daytime. The total capital cost is about £9,200, entailing a charge for interest and sinking fund of £506 per annum, leaving £1,300 for the cost of running the plant and repairs, a sum materially in excess of anything which would be at all possible.

The final conclusion at which I arrive is that it would pay the Urban Council to do the lighting of the whole of the street lights of the town, even if there were no additional lighting required and, further, that by so doing they would place themselves in a position to do the private lighting on any scale it might be desired at a moderate cost and with a profit to the rates.

Dr. Hopkinson proceeded to make a comparison of the illuminating power and the cost of gas and electricity. giving electricity at 8d. per unit as equivalent to gas at 5s. 4d., and electricity at 6d. per unit equal to gas at 4s.; and considering the great advantages of electric lighting in regard to health, to saving of decorations and to convenience for decorative purposes, says there is no doubt it is worth while to use it at even a substantially greater price than gas.

Coming to the series of tenders placed in his hand for consideration and report, we find five out of six are for the alternating-current system disapproved by Dr. Hopkinson; they are those of Messrs. John Fowler and Co., the Brush Electrical Engineering Company, Messrs. Crompton and Co., Messrs Siemens Bros., and the Capital and Counties Company. The only low-tension tender is that of Messrs. Sharpe and Kent, which Dr. Hopkinson regards as inadequate. He says: None of these propose to light the whole of the streets in the district, and this could undoubtedly be done with profit with the exception of a few outlying lamps, which it would be better to leave to the present source of supply, although they could easily be lighted electrically if no other method were available. Further, with the exception of Messrs. Sharpe and Kent's tender, they would all in my judgment be financially at a disadvantage, owing to their adopting the alternating-current system in a district where the distances are short and consequently requiring machinery to be running during the day time.

It may perhaps be convenient to state here that if arc lighting was desired in the streets there would be no difficulty whatever in providing it from the current system proposed for the lighting by incandescent lamps.

On the whole I am clearly of opinion that a reasonably bold policy is the most prudent one. You are sure of a good customer in yourselves for the street-lighting, which will at once place you in the position of being able to supply private lighting at such a moderate cost as will secure its adoption to a considerable extent.

Appended to the report are a couple of schedules, containing estimates (1) for lighting streets and for private lighting, (2) for lighting streets only. The details are—Schedule I.: boilers £1,528, feed-pumps £120, economisers £180, steam and waste pipes £400, four Willans engines (100 h p) and four dynamos (125 amperes at 480 volts) and one spare armature £3,076, condensers, etc., £435, accumulators £885, switchboards, etc., £680, conductors (mains) for private lighting £6,998, ditto for 480 street lamps and altering street standards £3,578, buildings (exclusive of site) £2,000, contingencies £1,988—total £12,868. Schedule II. shows an alternative estimate for street-lighting only, the total of which is £9,161, also apparently exclusive of site.

LEGAL INTELLIGENCE.

THE REGISTRATION OF DESIGNS.

In the Court of Appeal on Monday last, before Lords Justices Lindley, Lopes, and Kay, judgment was given in the case in *re* Clarke's Registered Design No. 206,870.

This was an appeal against the refusal of Mr. Justice North to order a design for a lamp for electric lighting, which had been registered under the Patents, Designs, and Trade Marks Acts by Mr. John Farrand Clarke, to be taken off the register, on the ground that the design was not new or original. The official certificate of registration given by the Comptroller stated that the design No 206,870 "was on February 1, 1893, registered in Class I., in the name of John Farrand Clarke, and that a copyright of five years was granted; also, that the claim under 'Statement of nature of design' is as follows: 'Lamp for electric lighting, application for its shape.'" The lamp is intended for use outside shop windows, so as to throw light upon the windows and the articles displayed therein The application to expunge the registration was made by Messrs. Julius Sax and Co, Limited.

Mr. Vernon Smith, Q.C., and Mr. Charles Church were for the appellants; Mr. Swinfen Eady, Q.C, and Mr. K. G Metcalfe were for the respondent.

Elaborate judgments were read by each of their **Lordships**, all three concurring that the appeal must be allowed.

Lord Justice Lindley said the design being on the register it was for those who disputed the propriety of its registration to show that at the date of registration this design was not new or original, and was well known in the United Kingdom The question is whether this is proved. His lordship held that it was. On the question of what constituted "novelty" in a case of this kind his lordship remarked that the design must be new or original with reference to the kind of article for which it was registered. A design might be new for a coal-scuttle, but not for a bonnet. On the other hand, a design for a shade of a gas lamp could hardly be new if it was old for an oil lamp. In the present case the design registered was for the shade for an electric light. If when registered the design was not new or original for all lamps, if the shape was common for such lamps as were used before electric lighting was invented, the design was one to which the Act did not apply, and the design ought to be expunged. Electric lighting being new, every lamp or lamp-shade adapted to it for the first time might be said to be new or original if attention was paid only to its application to the new method of lighting. But it was absurd to suppose that the application of an old-shaped lamp or shade to an electric light could be protected under this Act. There must be some novelty or originality in the shape as applied to sources of light in order that a design for the shape of a lamp can be protected. In this case the design registered was nothing more or less than an old and well-known lamp or lamp-shade, with the omission of a part which was wanted for gas or oil burners, but which is useless for an electric light. The old shape of lamp or lamp-shade consisted (1) of a reflecting screen of the same shape as the reflecting screen in the registered design; (2) of a ventilating top differing in no substantial particular from the ventilating top in the registered design; (3) of a chimney on the ventilating top, and which chimney is omitted from the registered design, not being wanted. The omission of the chimney rendered it necessary to cover in the ventilating top, but that did not really alter the shape of the lamp or lamp-shade. Mr. Clarke had adapted a well-known lamp or lamp-shade to electric lighting but the shape was the old shape, with the omission of a useless appendage. No doubt a combination of old shapes might result in a new or original design for shape; and if that is the result that design would be protected if registered under the Act. But when, as here, the old shape of an article well known in the United Kingdom consisted of three shapes of three parts placed one over the other, and the new shape was exactly like the old shape, except that unless the useless upper part was omitted, it could not be said that the shape of what is left was new or original or that the residuary shape had not been previously published.

The judgments of **Lord Justice Lopes** and **Kay** were to the same effect, and the appeal was allowed, with costs, and an order made to remove the design from the register.

COMPANIES' MEETINGS AND REPORTS.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY, LIMITED.

A meeting of this Company was held on Wednesday at Winchester House, Lord Sackville Cecil presiding.

After expressing great regret at the absence from the chair of Sir John Pender, and sympathising with him and his family on account of his long and dangerous illness, the **Chairman** said the present was an interim meeting, and it was not opportune to discuss large and important questions of policy. In moving the adoption of the report (an abstract of which has been given in these columns), Lord Sackville Cecil remarked that the falling off in receipts had arisen on the east side of South America—namely, the seaboard of Brazil, Uruguay, and Argentina; and was

Digitized by Google

sufficiently accounted for by the fact that for four months of the half-year the charges from that side of the Atlantic were reduced by 70 centimes, or nearly 7d. a word. On the question of compensation for low rates which might be derivable from the consequent increased volume of traffic, he remarked that it was a subject upon which there was still a great deal of misconception outside the small circle of those who were immediately engaged in the conduct of telegraph business. It was greatly to be wished that all who approached this subject should appreciate that there was not much real analogy between the results to be anticipated from lowering postages or carrying rates of commodities and those of lowering telegraph rates, and any inferences drawn from analogy between them required most careful scrutiny. When a cable was once full another had to be laid, at large initial expense, and it had to be manned and maintained in addition to what already existed. Therefore, after a certain turning point—which in telegraphy might soon be reached—they had, besides the additional working expenses, to contemplate interest on freshly-sunk capital. These considerations led up to the question of the best appliances for getting the maximum duty out of lines already laid, and the Board had lately entered into an agreement whereby they would obtain the use of quite the most modern automatic appliances for signalling through long cables. The Board were preparing generally for the unpleasant prospect of having to do the increase of the Company's work at less profit, and he looked for some addition to their working expenses in the future. The Amazon telegraph extension to Manaos would act as a feeder, and would, they hoped, settle down into a successful undertaking. With their allies, the Eastern Telegraph Company, and with the Telegraph Construction and Maintenance Company they had also joined in a new concern called the German Telegraph Company, having for its object the laying of a cable from Emden, in Germany, to Vigo, in Spain, whence there was a short cable to Lisbon, where their own main cable diverged. The new line was in course of construction, and if their hopes were realised it should carry a valuable North European traffic for their route, much of which was now lost to them.

Mr. Frederick Youle seconded the adoption of the report, and it was carried unanimously.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held yesterday at Winchester House, the chairman, Mr. W. S. Andrews, presiding.

The **Chairman**, in moving the adoption of the report and accounts, which were taken as read, said their takings had been £80,315, as compared with £82,815 for the corresponding period, showing a reduction of £2,500. The amount of business transacted had been larger, but the falling off in receipts was due to the losses which had been sustained in exchange and to the reduction in the tariff that had been made from time to time. They and the Platino Company showed an ingathering of £40,000 less than they would have done at the par of exchange. He thought the current half-year was likely to turn out less favourable, unless the rate of exchange improved. He proposed that a dividend of 5s. 3d. per share be declared, which, with the interim dividend already paid, was at the rate of £3 per cent.

Mr. Earle seconded, and the motion was carried.

The retiring directors and auditors were re-elected, and a vote of thanks was passed to the chairman, the Board of Directors, and to the managing staff.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Hamburg.—The Finanz Deputation want tenders for a crane for the electricity works by 26th inst.

The Hague.—The Dutch Colonial Office wants tenders by 27th inst. for the supply of galvanised iron wire for the telegraphic service.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadtrath, Prague.

Penaranda de Bracamonte.—Tenders for electric lighting of the town for a period of 15 years may be sent to the authorities at the Casa Consistoria, Peneranda de Bracamonte, Spain, by May 28.

Berlin.—Tenders are wanted by May 22 by the State Railway Direction for about 15 tons of copper in sheets, and about half a ton of brass wire. Particulars at the Rechnungsbureau, Berlin W, Schöneberger Ufer 1.

Coblentz.—Tenders are wanted by 30th inst. for the annual supply of 10,000 to 13,000 wooden telegraph poles for four years. Particulars from the offices of the Konigl. Ober-Postdirection, Coblentz, for 30pfg. (3d.).

Giessen (Germany).—Tenders will be received by the Administration of the Hessian Grand Ducal Railways up to 21st inst. for lightning conductors at four stations on Grünberg and Loudorf line. Particulars for 1·8 marks (1s. 10d.) at Giessen, Frankfurterstrasse 64.

Lisbon.—The Royal Portuguese Railway Company will receive tenders up to June 3 for the supply of small telegraphic stores. Application to the Chief Engineer, Stores Department, Santa Apolonia Station, Lisbon, and particulars also obtainable at 28, Rue de Châteaudun, Paris.

Paris.—Tenders will be received by the Prefect of the Seine at the Paris Tribunal de Commerce on May 23 for the installation and working for 10 years of the electric light at the Hospice de Brévannes. The estimate is about £5,533, and the maximum annual payment 27,600f. (about £1,080).

Gisburn.—Tenders are invited for the various works required in erection of new buildings for electric lighting plant and homestead purposes at The Woodlands, near Gisburn, for Chas. J. Massey, Esq., J.P. Quantities may be obtained on application to Mr. Charles Parsons, architect, 9, Grimshaw-street, Burnley.

Bray (Ireland).—The Town Council want tenders by May 17 for (1) a steam alternator, 75 kilowatts; (2) a Lancashire boiler 200 h.p.; (3) economiser and feed-pump; (4) a vertical high-speed engine. Specifications, etc., can be obtained from Mr. P. MacDonnell, town clerk's office, Town Hall, Bray, on deposit of two guineas.

India Office, S.W.—The Secretary of State for India in Council is prepared to receive tenders to supply (1) spans, (2) iron telegraph posts. The conditions of contract may be obtained on application to the Director-General of Stores, India Office, Whitehall, S.W., and tenders are to be delivered at that office by 2 p.m. on 19th inst.

Burton-upon-Trent.—The Council require tenders for the supply of 25,000 tons, or a portion thereof, of best screened gas coal. Forms of tenders and conditions of supply may be obtained upon application to Mr. F. L. Ramsden, manager and engineer Gas and Electric Light Works, Wetmore-road, Burton-upon-Trent; and sealed tenders, endorsed "Coal," are to be delivered to the manager at or before 10 a.m. on 27th inst.

Bucharest.—Tenders are wanted by the Municipal Administration of Bucharest by June 24 for a concession for lighting the city for a period of five years. A security of 15,000 lei (about £600) will be required. The Municipal Authorities of Bucharest ask for further tenders up to June 24 for lighting the suburbs and environs "on a system without (underground) pipes more suitable than those that have been already offered." It is desired to replace 3 265 petroleum lamps, and the contract will be for five years. Communications should be sent to the Mairie at Bucharest.

Hammersmith (London).—The Vestry want tenders for the following: (*a*) the supplying and laying of high-pressure and low-pressure cables and pipes; (*b*) the supply and erection of arc lamps and lamp-posts; (*c*) the supply and erection of transformers and sub-station equipment; (*d*) the supply and erection of a five-ton overhead travelling crane. Specifications, general condition, and form of tender can be obtained at the office of Mr. A. H. Preece, 39 Victoria-street, Westminster. Applications for any one or all of the above sections must be accompanied by a cheque for £2. 2s. which will be refunded on receipt of a bona fide tender. Sealed tenders, endorsed "Cables," "Arc Lamps," "Transformers," or "Crane," must be delivered at the offices of the Vestry, 57, Fulham Palace road, Hammersmith, by noon on 27th inst. Mr. W. P. Cockburn, vestry clerk.

RESULTS OF TENDERS.

Morley.—The Town Council have accepted the tender of Messrs. Graham, Chapman, and Co. to fix the electric light to the stage fittings at the town hall for £44. 12s.

Bradford.—The Town Council have accepted the tender of Messrs. J. Moulson and Sons for the construction of a reservoir and tank at the new electricity works, Valley-road, for the sum of £890, Messrs. Broxup and Sons having declined to proceed with the contract.

London.—The Metropolitan Asylums Board have accepted the tender of Messrs. Cox-Walker's for the provision of telephones, electric bells, and fire alarms for the Brook Hospital and Ambulance Station, in accordance with drawings and specifications prepared by Prof. A. B. W. Kennedy, at the sum of £658. 7s. 6d. The following is a list of the other tenders received:

Brown and May, Limited, Devizes	£534	19	0
Pearson's Automatic Fire Indicator Company, Limited, Westminster	572	16	0
L. Alwyn, Queen Victoria-street	662	0	0
Tabor and Hinchcliffe, Cambridge	706	0	0
Mason, Wathes, and Brown, Leicester	722	18	6
Consolidated Telephone Construction and Manufacturing Company, Limited, Shaftesbury-avenue	784	16	5
Private Wire and Telephone Installation Company, Cannon-street	1,009	5	10
Vaughan and Brown, Limited, Kirby-street, E.C.	1,010	0	0
W. J. Furse, Nottingham	1,024	2	3
Strode and Co., Regent's Park	1,433	0	0
W. Seymour, Chelsea	1,500	0	6
Julius Sax and Co., Limited, Ridgmount-street, W.C.	1,657	2	0
C. E. Zimdars, Gray's-inn-road	1,900	0	0
National Telephone Company, Limited, Marshalsea-road, S.E.	2,032	0	0
Single Wire Multiple Telephone Signal Company, Limited, Old Broad-street, E.C.	2,244	0	0

Hampstead.—The Vestry have accepted the tender of Messrs. S. Z. de Ferranti, Limited, for the steam alternator and switchboard, at the price of £3,397. They have also accepted the tenders of the Brush Electrical Engineering Company for the tank and

Digitized by Google

appurtenances at £408. 10s., and the feed-water heater and steam pipes at £942.

Brighton.—The following tenders were received for the preparation, supply, and delivery at Brighton of cast iron and drawn-steel bracket posts for suspending electric light arc lamps, for the Corporation :

Reed and Son, Brighton (accepted)	£2,460
Hart, Son, Peard, and Co., Limited, Birmingham	2,500
Mackenzie Bros., Edinburgh	2,500
Manlove, Alliott, and Co., Limited, Nottingham	2,605
Lloyd and Co., Abercarn	2,800
Macfarlane and Co., Glasgow	3,060
Newton, Chambers, and Co., Limited, Sheffield	3,840

BUSINESS NOTES.

Wells.—The Town Council have decided not to instal the electric light.

London.—The church of Allhallows-on-the-Wall is to be lighted by electricity.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,580.

Blackburn.—The Town Council are about to apply for leave to borrow £10,000 for electric light extensions.

Grimsby.—The Lighting Committee have decided to purchase a new dynamo for the town hall at a cost of £144. 10s., capable of 110 volts.

Exeter.—The Electric Lighting Committee propose to give a day as well as a night service, and have offered special terms to the hospital.

The South Staffordshire Tramways.—The Board of Trade have sanctioned the use of steam on these tramways for a further period until March 25 next.

St. Helens.—Mr. Samuel Glover, the gas manager, is to have the superintendence of the new electrical works, but he will have an electrical engineer under him.

Armagh.—The governors of the county asylum have decided to light the new hospital with electricity, and have appointed a committee to go into the question.

Hong-Kong.—The business of the electric light company of Hong-Kong is extending so rapidly that the question of providing additional plant is under consideration.

Dover.—The Corporation have received official sanction to their scheme of electric tramways, and the work will be proceeded with immediately at an estimated cost of £50,000.

Paisley.—The Town Council have decided to delay deciding whether a resident or a consulting engineer should be appointed in connection with the proposed electric lighting.

Great Horton.—At the half-yearly meeting of the Industrial Society, a proposal of the directors that an electric light installation be fitted up at the central stores was agreed to.

Sunderland.—The Avenue Theatre will shortly be lighted throughout by electricity, and a special feature will be made of the electric lighting during the forthcoming pantomime.

New Company.—The British Horseless Carriage and Motor Cycle Company, Limited, has been registered by Lumley and Lumley, 37, Conduit-street, W., with a capital of £10,000 in £1 shares.

Clapham (Yorks).—This village is now lighted by electricity, which was switched on last week for the first time. There are over 1,000 yards of cable, and in the streets 10 32-c.p. lamps have been placed.

Chelsea Electricity Supply Company, Limited.—Letters of allotment and regret for the issue of 12,000 ordinary shares were posted on Tuesday. The issue was, we are informed, considerably over-subscribed.

Sheffield.—The House of Commons Committee have passed the preamble of the Corporation's Tramway Bill and authorised the purchase of the tramway company's plant at the expiration of their lease in July.

Torquay.—The Town Council have received a letter from the Local Government Board stating that one of their inspectors would hold an enquiry concerning the proposed electric lighting installation as soon as possible.

The Jandus Arc Lamp.—We have received from Messrs. Drake and Gorham printed copies of testimonials received from a large number of firms as to the Jandus lamp. The lamp has been fully described in our columns.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending May 10 amounted to £1,162, as compared with £1,159 in the corresponding week of the previous year, being an increase of £3.

Kidderminster.—The gas company have endeavoured to obtain a *locus standi* with reference to the Bill for the Kidderminster and Stourport electric tramway, on the ground that their mains might be effected and explosions occur.

Bexhill.—At the meeting of the Urban District Council, the Clerk said he had received plans and notice of the application made by Earl De La Warr to supply electric light to Bexhill. The matter was referred to the Highways Committee.

Bradford.—The Town Council have approved a plan showing a proposed rearrangement of gas and tar pipes and condensing and scrubbing plant at Thornton-road Gasworks, and have instructed the engineer to carry out the work at an estimated cost of £1,400.

Islington (London).—At the meeting of the Vestry the clerk read a communication from the principal officers of the Vestry, including Mr. Gay (electrical engineer), asking for permission to accept articled pupils. The matter was referred to the General Purposes Committee.

Bury St. Edmunds.—The report of the Electric Lighting Committee, as to which there have been various rumours, will not be delivered until next month. So far as the report is concerned, it is believed that the matter in question is really the amount of the area to be undertaken.

Cheltenham.—Mr. Norman, in submitting the minutes of the Electric Lighting Committee at the meeting of the Town Council, mentioned that a tasteful pattern of standards for electric arc lamps had been approved, and that in all 6,600 lamps had now been wired. The minutes were approved.

Hull.—At the meeting of the Town Council a vote of thanks was passed, on the motion of Alderman Fraser, seconded by Alderman Massey, and supported by Alderman Seaton, to Councillor Holder for his services to the town in his capacity as chairman of the Electric Lighting Committee.

Glasgow.—The electrical engineer of the Corporation is preparing a specification for the electric lighting of the Ruchill plant. The Tramways Committee will, it is understood, recommend to the Corporation the adoption of the overhead electric system, with provision for seats on the top of the cars.

Acton.—At the meeting of the District Council a letter was read from Mr. Goddard on behalf of Mr. Cohen with reference to the electric lighting. The Chairman reminded the Council that Mr. Goddard had been asked to put any propositions he might have to make. The letter asked the Council to purchase for £2,600.

Killarney.—At the meeting of the Town Commissioners the clerk produced a legal document, served at the instance of Messrs. Huggard and Willington on him, in the matter of the auditors' surcharges for money amounting to £85 paid the Killarney Electric Lighting Company for public lighting, which is now in the Court of Queen's Bench.

City and South London Railway.—The returns for the week ended May 10 were £909, compared with £832 for the corresponding period of last year, being an increase of £77. The total receipts for the half-year terminating as above were £17,936, compared with £17,815 in the same period of the preceding year, being an increase of £121.

Calcutta.—It is stated that three firms in Calcutta have taken up the matter of the supply of electricity in the city. It is hoped that the tramway company will substitute electrical for animal power to propel their cars. It is obvious that in a city like Calcutta there are greater difficulties in the way of animal traction than in a cooler climate.

Tamworth.—At the meeting of the Town Council a letter was read from the Postmaster General to the effect that he considered the electric fire-alarm from the workhouse to the fire brigade station an infringement of his exclusive telegraph rights, but would allow it to remain on payment of the nominal fee of 1s. per annum, which was agreed to.

Folkestone.—At the meeting of the Town Council a long discussion took place on the electric light question with regard to the disposal of the provisional order, but it was eventually decided to postpone the matter for a fortnight. The Electricity Bill has passed through the House of Commons and is now in the Lords. It is likely to become law at an early date.

Chelmsford.—At the meeting of the District Council a letter was read from Mr. G. W. Clark, of East Hanningfield, asking for permission to erect some poles to carry overhead some electric lighting wires. Mr. Clark has an electric installation of his own, and wants to supply one or two other residents of the parish with the light. The matter was referred to a committee.

Derby.—At the meeting of the Town Council, Mr. Naylor asked a question with regard to two new transformers that it was proposed to erect at a cost of £268. They were so unsightly that he should be pleased if the matter could be so reconsidered as to render their erection unnecessary. Alderman Leach said it was a matter that was under consideration, but they were unable to do it at present at any rate.

Northam.—Mr. Grant, the engineer for the electric power company, has been at Northam for four weeks seeking the most suitable spot on which to erect the works of his company. After exhaustive tests he has decided on locating them at East Northam. A huge dam for the company is being constructed on the Mortlock river. Necessary properties have been under offer some time, and will now be acquired.

Bury (Lancs.).—The new electric lighting works will probably be ready by the autumn. A deputation from the tramway company have met the members of the Sewering, Paving, and Streets Committee with reference to the working of the tramways in the borough by overhead electric traction, and a deputation has also been appointed by the Corporation to visit Bristol, where electric traction is in operation.

Colchester.—The Town Council have accepted Mr. A. T. Osborne's offer to sell for £500 a piece of land adjoining Stanwell-street depôt for an electric light station, as also the Colchester Brewing Company's offer to sell for £100 a piece of land 72ft. by 15ft., adjoining the north side of Mr. Osborne's land. It was reported that the plan of the district proposed to be lighted had been prepared, and tenders had been invited.

Digitized by Google

Merthyr.—With regard to the provisional order applied for by Mr. Howell, of Llanelly, for the public lighting of Merthyr by electricity, the Urban District Council have received a letter from the Board of Trade stating that they had granted the order, subject to the area of supply being reduced from a mile to half a mile of the centre of the town. The Council approved of the restriction.

Amalgamation.—We are informed that an amalgamation has been effected between the Nalder and Harrison Construction Syndicate and Messrs. Swinburne and Co., Limited. For the purposes of this amalgamation it has been found advisable to dissolve the syndicate, and the amalgamated businesses will be in future carried on as a private firm under the title of Messrs. Nalder and Hilton, who have purchased the two businesses.

Newport (Shropshire).—The Lighting Committee's report, recommending the acceptance of the gas company's contract, caused considerable discussion at the meeting of the Urban Council, in the course of which a letter was read from Messrs. Robinson and Molyneaux saying they intended to lay down an electric lighting plant at their works, and would be prepared to light the district. Ultimately the report was adopted.

Halstead (Essex).—At the meeting of the Rural District Council the surveyor reported that he had received a report and plans from Messrs. Crompton and Co. on the matter of lighting the town by electricity. The report was referred to the Lighting Committee to report upon. On the suggestion of Mr. Clark, the surveyor was instructed to prepare a table showing the average cost of lighting the town and the public offices during the past three years.

Lurgan.—The Commissioners are considering the propriety of having the town lighted by electricity during the present season, and a committee has been in communication with an electrical engineer on the subject. It is proposed to supply 15 lamps, extending from the railway station to Queen-street, with elevated wires, at a cost not exceeding £500. The chairman of the Commissioners has been requested to confer with the Lord Mayor of Belfast, as an authority on the subject.

Mitchelstown.—We understand that preliminary steps are about to be taken by Mr. Webber, the landlord of the Kingston estates, to promote a scheme for the electric lighting of the town. It is understood that the Board of Guardians will be asked to give the necessary authority for the scheme. About 40 electric street lamps will probably be required, and it is expected that the principal inhabitants will contribute materially to the undertaking by using the light for domestic purposes.

Cable between Hawaii and Japan.—A telegram from Washington says that the Committee of the Senate on Foreign Relations have agreed to a compromise with regard to the Bill providing for a cable between the Hawaiian Islands and Japan. The Bill authorises the Postmaster-General of the United States to make contracts on behalf of the latter with any company that may undertake the laying of the new cable, and to pay them a Government subsidy not to exceed the sum of 160,000dol. per annum.

Oldham.—At the Town Council meeting, Mr. Harrop, on the minutes of the Electric Lighting Committee, commented upon the acceptance by the committee of Prof. Kennedy's recommendation limiting the firms to be asked to tender for the supply of dynamos by the insertion of a qualification that tenders would only be considered from those firms who had already manufactured plant of about the size required. On the suggestion of the town clerk, the chairman promised to take as an instruction to his department that invitations to tender be sent to Oldham firms.

Cambridge.—The following is the revenue return for the March quarter, 1896, of the Cambridge Electric Supply Company, Limited: number of units sold during quarter, 65,425; number of lamps connected March 31, 1896, 15 952; revenue from electricity supply, March quarter, 1896, £1,767. 10s. 9d., March quarter, 1895, £1,273. 3s. 3d.; revenue from meter rents and other sources, March quarter, 1896, £60. 19s. 1d., March quarter, 1895, £49. 13s. 6d.; total revenue, £1,828. 9s. 10d., as compared with £1,322. 16s. 9d. in the corresponding quarter of 1895.

Burnley.—At the meeting of the Town Council the General Purposes Committee were authorised to carry out the works necessary for the lighting by electricity of the technical school at an estimated cost of £205. The Gas and Electric Lighting Committee asked for permission to lay additional mains in Church-street for the supply of electric light at an estimated cost of £165. Councillor Thornbee asked if a sufficient number of promises had been given to justify a cable being laid in Church-street? Councillor Bibby replied that they had plenty of guarantees for the cable.

Bromley.—At the meeting of the Rural District Council the Works Committee reported that an offer from the National Telephone Company to provide fire-alarms in Durham-avenue, Beckenham-road, and Croydon-road was submitted, but as the company attached a condition that they should be allowed to erect telephone posts along the public highway for this purpose, and use posts, in addition, for the general business purposes of the company, the committee recommended that before considering the matter a plan be applied for showing the position of the proposed posts. The report was adopted.

Canterbury.—The following report of the whole house committee of May 1 (16 members present) was brought up at the last meeting of the Town Council: "The committee recommend as follows: (*a*) that electric lighting be established in the city by the Corporation, and that the necessary steps be taken for that purpose; (*b*) that Mr. R. Hammond, M.I.E.E, be engaged as the engineer to lay the mains and generally carry on the works; (*c*) that application be made to the Local Government Board for sanction to a loan of £20,000 to carry out the above works." The Council adopted the report by 13 votes to 4.

Appointments Vacant.—The Committee of the City and Guilds of London Institute have announced that they are prepared to appoint a professor of mechanical engineering and applied mathematics at the Finsbury Technical College. Besides classes, the professor will have to superintend the workshops and give instruction in machine designing and drawing. The salary is £600 a year; and application should be made to the hon. secretary at Gresham College, E.C., by June 8.—The borough of Salford are about to appoint a chief lecturer in chemistry for the Salford Technical Institute, at a salary of £200.

Stockton.—At the quarterly meeting of the Town Council a committee reported on the electric light, which would cost £18,000 to instal in Stockton for public purposes. The Board of Trade provisional order to the Corporation would expire in August next, and if the work were not commenced by that time a private company could step in. This was most undesirable, as the company would probably have to be ultimately bought out. The committee, having regard to the heavy rates, recommended that application be made to the Board of Trade for a further extension of time, during which the rates might be reduced. This was agreed to.

Crewe.—At the last meeting of the Town Council Councillor C. H. Pedley gave notice that he should bring before the next meeting of the General Purposes Committee the question of electric tramways for the town, running north, south, east, and west. He thought they would be a great boon to the inhabitants. He had reason to believe that it was possible to get someone who would not only obtain a provisional order, but would themselves lay down the tramway and work it when completed. He mentioned this so that the Council might think about it, for no one would apply for a provisional order except with the consent of the town.

City of London Electric Lighting Company, Limited.—The following is the gross revenue return for the quarter ended March, 1896: sale of current for public lighting, £3,161—corresponding quarter last year, £3,191; sale of current for private lighting, etc., £38,280—corresponding quarter last year, £26,622; other sources (estimated), £750—corresponding quarter last year, £340; total, £42,191—corresponding quarter last year, £30,153. This is an increase on the corresponding quarter of £12,038. The equivalent of 8 c.p. lamps connected on March 25, 1896, was 207,268, an increase during the quarter of 11,951; equivalent of 8-c.p. lamps connected on March 26, 1895, was 148,594, an increase of 13,134.

Catalogue.—We have received from Messrs. F. and C. Osler, of 100, Oxford street, W., a catalogue of designs of fittings for electric light. The catalogue contains illustrations of some graceful and handsome ornamental fixed and sliding pendants, ceiling lights, brackets, etc. There are some very pretty standard and table lamps, and some novel and graceful Royal Worcester porcelain figures, designed to carry electric lamps. A few French bronzes only are shown, but these are of a highly artistic order, and serve to illustrate the endless fields that are open to those who strive to combine utility and beauty. Messrs. Osler supply fittings at all prices, but even the cheapest are beautiful in outline and design.

Peterborough.—Mr. F. H. Tulloch, inspector of the Local Government Board, has held an enquiry with regard to the application of the Town Council for sanction to borrow £20,000 for electric lighting works. Mr. H. Percival, barrister, appeared to oppose for certain ratepayers, and Mr. Capell appeared for the Great Northern Railway. The objection raised by the barrister was that the margin of borrowing powers of the Corporation (£42,503) was pledged for duplication of the water-main, and for providing municipal and other offices, and they also objected to the smallness of the area to be lighted. Prof. Fleming described a scheme, and said there would be no difficulty in supplying the whole borough.

Newport (Mon).—The electrical lighting is progressing rapidly, and already it has become necessary, in consequence of the large number of applications for the light in Commercial-street, to increase the size of the low-tension mains in that section of the leading thoroughfare between Skinner-street and Hill-street. The small converters will be replaced by large ones, which will be sufficiently powerful to indicate finality. The capacity of the mains will then be sufficient in that part of the inner area to deal with all possible future installations. The small converters will be valuable for use elsewhere in the district. We understand that the Electricity Committee of the Town Council are considering an estimate of the cost of an extension to Maindee.

Hampstead.—At the meeting of the Vestry the Lighting Committee recommended that an electric main be laid in Abbey-road, from Boundary-road to Belgrave-road, for the supply of current to private consumers, at an estimated cost of £90. 15s. 6d. This was adopted. Mr. T. I. Johnson complained of the delay in presenting a copy of the electric lighting accounts to the Vestry, and enquired whether there was any probability of their being published before the elections. It was explained that the accounts, in the form prescribed by the Board of Trade, had been before the committee; but that, being of a complicated nature, the vestry clerk had been instructed to prepare a statement to accompany them. The accounts were always open for the inspection of any vestryman.

Aberdeen.—The Town Council have decided to proceed with an extension of the electric lighting works at an estimated cost of £4,500, and that two new boilers, with water-heater and feed-pumps, be obtained at an outlay of £3,000. It was also agreed

Digitized by Google

that the main should be extended from Union street round Golden-square at an expenditure of £300, and the main in George-street for a distance of 40 yards beyond the Northern Hall. at an expense of £280; but that no action should in the meantime be taken as regards the subject of the extension to the west end of the city, and that the question of the extension of the mains to the harbour district should be deferred. A sub-committee is engaged in considering a scheme for the electric lighting of the harbour and quays.

Waterloo-with-Seaforth.—The following communication from the Board of Trade was read at the last meeting of the Urban District Council: "Sir,—I am directed by the Board of Trade to transmit to you the enclosed copy of the Great Crosby and Waterloo Provisional Order, in the form in which, subject to any observation they may receive, they propose to issue it, and to request that if the District Council have any observations to offer thereon this department may be favoured with them at the earliest possible moment." The Solicitor said the copy which had been sent down was practically an exact copy sanctioned by that Council previously. There had been one or two clauses inserted having reference to the Great Crosby district, but so far as Waterloo was concerned there was nothing more in it.

Swansea.—We understand that there is a possibility of the revival of the triple scheme, under which the Corporation proposed to establish a dust destructor, work the tramway system, and light the streets by electricity. It will be remembered that a Bill for the acquisition of the tramways was deposited in Parliament for promotion by the Corporation during this session, but it had to be withdrawn owing to a misunderstanding of the arrangement arrived at with the tramways company. We learn that there is now a chance that the Bill, or some modified form of it, may be revived even in the present session of Parliament, and that should the necessary arrangements not be made sufficiently early for this to take place, it will be proceeded with in the next session.

Dundee.—The question of providing an additional electrical storage battery for the city was under consideration at the last meeting of the Gas Committee of the Town Council. The estimated cost is £832. 10s. It was resolved to report the whole matter to the Town Council for their instructions. The new battery would exactly double the storage capacity, it being a duplicate of the storage battery at present in use. The Works Committee of the Town Council, after considering the proposal to lay underground telephone wires in Dundee, have decided to delay coming to a decision until a full report has been received from the burgh engineer. The sum collected for electricity rental for the 12 months ending April was £4,882 2s. 10d, an increase of £1.206. 17s. 6d. for the last year.

Elgin.—At a meeting of the County Council there was submitted a letter from Mr. John E. Gordon, M P., enclosing a communication from the Postmaster-General intimating that, after careful enquiry, he now saw his way to erect a telephonic trunk wire between Aberdeen and Inverness. The matter was now in the hands of the Treasury, and would be pushed on rapidly. There was also read a long communication from the County Council of Fife, accompanied by a request for the co-operation of Elgin County Council, with the view of obtaining from the Post Office special terms for the use of the telephonic system on trunk wires. According to the Post Office Act, the Post Office could give no modification at all on the present scale. Before that could be done a new Act would require to be passed.

Paddington.—At the last meeting of the Vestry, Colonel Barchard, the chairman of the Electric Lighting Committee, reported the result of the committee's application to the Metropolitan Electric Supply Company, Limited, for a reduction in their charges, which from Lady Day last will be as follow—viz.: for public and trade purposes—when the consumption exceeds five units per 8-c.p. lamp per quarter 5d. per unit, and when the consumption is less, 6d. per unit. The gallant colonel's report was received and adopted with evident satisfaction. He then moved and it was agreed: "That the Board of Trade be informed that this Vestry have no suggestion to offer with reference to the additional system of supply proposed to be adopted for the purposes of the Paddington Lighting Order, 1890."

Barrow.—The Town Council have decided that Mr. E. Manville be asked to visit Barrow and submit a report on the best system of electric lighting for the borough, with estimates of cost, maintenance, and probable revenue, and that before his visit the town clerk write the Furness Railway Company, the Barrow Hematite Steel Company. and the Naval Construction and Armaments Company asking whether, in the event of an installation being laid down, they would be prepared to take electricity for lighting or power, and if so, to what extent. It was also decided that the town clerk write Mr. Emile Garcke, representing the Barrow Tramways Company, asking whether, in the event of an installation being laid down, the company would be prepared to take electricity for the purpose of working their tramways.

Falmouth.—At the Urban Sanitary Authority's meeting the following letter was read from the Postmaster-General: "With reference to your letter of March 5, forwarding a petition from the Mayor, aldermen, and burgesses of the borough of Falmouth, asking for the extension of the trunk telephone system to Falmouth and Penzance, I am directed by the Postmaster-General to inform you that, after careful consideration, his Grace is prepared to recommend to the Lords Commissioners of the Treasury the erection of a trunk circuit to Falmouth. The Postmaster-General expresses his regret that the circumstances do not at present justify him in recommending the extension of the trunk system to Penzance, but he assures the memorialists that the claims of that town shall be borne in mind in the consideration of the extensions of the system."

London County Council.—At the meeting of the Council the Bridges Committee brought up a long report with reference to a proposed foot-passenger tunnel under the Thames between Greenwich and Millwall. The total estimated cost of the works would be £65,000, and of the land £5,000 It was proposed to light the tunnel by electricity, the committee having received an offer from the London Electric Supply Corporation to lay a cable to the tunnel for £1,000, and to supply electricity at 4d. per Board of Trade unit. The committee recommended that the Council should apply to Parliament for power to construct a foot-passenger tunnel at an estimated cost of £70,500, but this was postponed. Upon the recommendation of the Finance Committee it was agreed to lend the Vestry of St. Pancras £15,300 for electric lighting purposes.

Fareham.—The District Council have had before them a lengthy report on the necessary work in connection with the electric light undertaking which was presented by the electrical engineer (Mr. Manville). It dealt mainly with the best method of providing better lighting in certain streets, the replacing of certain lamps, and the cost of putting wires underground, in compliance with the Board of Trade requirements. The total cost he estimated at £1,428. The plant in the generating station also required duplicating, and he recommended the installation of a new arc light machine and a new alternator with two small engines—one to drive the alternator and one to drive the arc light machine. The cost of these duplicates he estimated at £1,025, this being the estimate for a complete new plant. The report was referred back to committee for consideration.

Belfast.—A deputation from the Paisley Commissioners visited the town a few days ago and went to the electric light station in Chapel lane, where they were received by the engineer, Mr. V. A. H. M'Cowen, who explained the working of the engines and the switchboard. The deputation was joined by the chairman of the Electric Committee of the Corporation (Councillor Andrews, J.P.) and Councillor Sir Wm. M'Cammond, J.P., and, after the chairman had informed the visitors of the origin and progress of the Corporation system of electric lighting and the probable development of the concern at no distant date, an adjournment was made, at Councillor Andrews's invitation, to luncheon, at which the party was augmented by the presence of other members of the Electric Committee The deputation seemed much gratified by the information they received during the day.

Douglas.—The laying of the lines of the Southern Electric Tramways is practically finished, and the work has been carried out in the most substantial manner. The building to contain the tramcars is finished, and the power station will shortly be completed. The three new steel bridges are on the ground, and one is erected in position, the other two being well advanced. The electrical machinery, all of the latest and most improved pattern, is on the ground, and the motors are being fitted to the cars as they arrive. The boilers are being placed in position, and all works are being actively pushed forward with a view to opening the lines for traffic in June. The present terminus of the lines at the south end of the Marine Drive is at the commencement of the footpath leading to Port Soderick, to which place it is proposed to extend the tramways at the end of the coming season.

Portsmouth.—A special meeting of the Electric Lighting Sub-Committee has been held to consider what steps should be taken to stop a disturbance among some of the stokers employed at the electric light station. It appears that a stoker was recently appointed to fill the place of one who had left, but as he was new to the work a young fellow, aged 18½ years, who had been employed in the coal bunkers at the station, was appointed to help the stokers, with whose work, it was said he was thoroughly familiar. Two of the men refused to work with their young mate, on the ground that he was only a boy, and should not be filling a man's position. It was pointed out at the meeting that the Trades Council laid it down that a lad over 18 years of age should receive a man's pay. After the two men objecting had given their explanation of the matter it was unanimously decided to dismiss them at once

Electric Lighting for Mar Lodge.—An exceptionally open winter has enabled the contractors for the Duke of Fife's new residence at Braemar to make substantial progress. Simultaneously with the erection of the house are proceeding the arrangements for lighting it by electricity. For this purpose his Grace has decided to utilise the Falls of Corriemulzie. Near the site of what was New Mar Lodge a reservoir will be formed, whence the water will be run through 12in. pipes to a turbine at the bottom of the ravine This wheel will drive the dynamo and generate the current, which will then be carried across the Dee on overhead wires to the new residence, adjoining Old Mar Lodge on the north side of the river. The water will give a force of 50 h.p., which will suffice not only for lighting, but also for heating, and probably culinary purposes. The falls will only be tapped at night-time.

Morley.—The Town Hall Committee reported at the last meeting of the Town Council that they had arranged with Messrs. Graham, Chapman, and Co. to continue the working of the electric light plant at the town hall for a few weeks on the same terms as the old contract. The Town Clerk said the committee thought it wise to make a temporary arrangement with Messrs. Graham and Chapman to continue as the electric light engineers of the town hall until the proposed scheme for lighting the town was started, when a man should be appointed to look after the whole. It was

Digitized by Google

stated that it had been decided to fix the electric light to the stage fittings at the town hall in consequence of a suggestion made by the insurance company. It was supposed that the company considered it safer to have electric footlights for the stage, and the insurance tariff would be more reasonable if they adopted the suggestion. The report was adopted.

Liverpool.—At a meeting of the City Council Alderman Cookson moved a recommendation of the Health Committee that the Council consent to the National Telephone Company, Limited, laying their wires under the streets in the city on condition that the company undertake to substitute the twin-wire system for the present single-wire system throughout the city, subject to the company entering into an agreement with the Corporation, the draft of which had been approved by the committee. He mentioned that the Corporation paid somewhere between £800 and £900 a year for the use of telephones, and under this arrangement they would get back a minimum of £875 with an increased rent when the system extended. The Town Clerk, replying to several councillors, said the telephones were supplied to the Corporation at a considerably reduced cost compared to the cost of those supplied to ordinary subscribers. The recommendation was agreed to.

Coventry.—Mr. T. R. Whitehead, of Leeds, has been appointed secretary and manager of the tramways, vice Mr. H. O'Neill, resigned. At the meeting of the City Council, a certificate, in accordance with the terms of the agreement entered into in 1893 between the Mayor and Corporation and Mr. Graff Baker, was laid before the Council by the town clerk, showing the cost of the tramways undertaking. The amount, together with the expenses of the equipment, was shown to be £34 960. Mr. Andrews enquired whether details were given of the separate cost of buildings, cars, and so on. The Town Clerk said they were not given in the certificate, but they were set forth in the accounts on which the certificate was based, and which were considered confidential. The specification set out all the cost of roads, poles, cars, engines, and everything which is part of the tramways. On the motion of Alderman Tomson, seconded by Alderman Marriott, the certificate was ordered to be entered upon the minutes. Coventry will be connected with the postal telephone service on May 30.

St. George's, Hanover-square.—The special committee of the Vestry appointed to enquire and report upon the question of electric lighting and its relation to the destruction of dust and trade refuse have recommended that no step be taken on account of the great initial cost, and in the increase in the annual cost of the removal of the dust by the Vestry over the present cost of removal by contract, and also on account of the great difficulty of obtaining a suitable site within the parish. The committee, however, recommended that when the St James's Vestry carried out the lighting of Piccadilly by electricity, the Vestry should extend the lighting by electricity from St. James's-street to Knightsbridge at an annual cost of about £1,230 as an experimental trial. It was pointed out in the course of a discussion on this report that the cost of erecting the destructor and installing the light would be about £70,000. There was no open space in the parish for the erection of a destructor. The first part of the recommendation was carried, but the second, relating to the lighting of St. James's-street, was deferred, as there was a tie in the voting.

Blackpool.—The Electrical Committee have had before them the nine selected candidates for the post of electrical engineer. Ultimately the two following gentlemen were selected, from whom an appointment will finally be made: Mr. R. C. Quinn, of Brighton, and Mr. A. T. Cooper, of Blackpool. The final selection is to be made this week. A return has been issued showing the financial result of the working of the electric light department during the year ending March 25 last The return shows that the total receipts have been £6,865 17s. 6d., made up as follows: public arc lighting, £1,589. 19s 11d.; private arc lighting, £247. 6s. 1d.; and alternating current, £5,028. 11s. 6d. The cost of production at the electricity works was £3,904. 11s. 4d., equal to 2·7d. per unit. The chief items in the expenditure were: coal, £1,438; oil and waste, £277; water, £248; manager's salary, £200; electricians, £408; wages, £704; repairing (wages) £195; materials, £371. The total cost of the current produced, however, was £6 858. 3s. 4d., equal to 4·8d. per unit, the following items, of course, having to be added to the first cost at the works: rates and taxes, £110; insurance, £14; office and general expenses, £401; interest and sinking fund at 5¾ per cent., £2,428 The cars on the electric tramways will be running to St. Annes from Blackpool at Whitsuntide, and the whole length will, it is expected, be completed by about July, as the fine weather has enabled several gangs of men to push on with the laying of the metals.

Leeds.—The Leeds Corporation are about to further test the durability of a compound tramway rail patented by Mr. William Towler, a local citizen. About 18 months ago two 30ft. lengths of this kind of rail were put down as an experiment in a portion of North-street where the tramway traffic is very heavy. This experiment having proved entirely satisfactory, the Council, on the recommendation of the Highways Committee, have given an order to Mr. Towler for sufficient rails for one mile of single track. These will be laid down somewhere on the route of the proposed new electrical tramway between Sheepscar and Kirkstall. The ordinary rails now in use on tramways are solid pieces of metal, the usual 30ft. length weighing about 100lb. Mr. Towler claims that by the use of his patent inconvenient disturbance of the roadway might be obviated. His patent compound rail, as the name implies, is in two pieces, the upper portion of which can be removed and replaced when worn out without disturbing the lower portion of the rail. The necessity of pulling up more than a single row of paving stones on either side of the line is thus dispensed with. The upper part is secured to the under part by bending its flanges so as to clip the head of the under rail. This can be done by means of cramps, or by a special tool, that can be traversed along the rail, and which is fitted with a pair of adjustable rollers, which bend the flanges so as to grip the lower rail. The top rail, when worn out, it is said, can be readily detached by means of simple levers. Mr. Towler calculates that the upper part of his patent rail may be replaced at £572. 16s. a mile.

Worcester.—Colonel Marsh, Local Government Board inspector, has held an enquiry into the application of the Corporation for sanction to borrow £6,580 for purposes of electric lighting, and for the appropriation of £504 out of the enfranchisement money for the purchase of certain lands in Pitchcroft. The Town Clerk explained that the latter was a continuation of the scheme for acquiring Pitchcroft as a place of recreation for the city, a large portion of which had already been acquired. The money asked for in connection with the electric lighting of the streets was for an extension of the mains and additional lamps, and for work at the generating station. At the meeting of the Watch Committee it was reported that the Electricity Committee proposed to put another arc lamp in Barbourne, near the south end of Spreckley's brewery, instead of outside the Catholic Church, Sansome-place, and an additional one in the same road opposite Shrubbery-avenue, at a cost of £49. Alderman Williamson said that the authorities of St. George's Catholic Church had agreed to put the electric light into the church and schools if the Council would put a street lamp outside the church. But the church people had afterwards withdrawn from that agreement, and as there was no real public purpose to be served in placing a lamp there, it was proposed to be put where it was more wanted. Mr. Millington thought that was not the case. The Corporation withdrew from the agreement, and not the church people. It had been arranged to put the street lamp in an arch over the entrance. Alderman Williamson replied that the electrical engineer had understood that, whether the lamp was put there or not, the electric light would not be put in the church and schools.

Shoreditch.—The Electric Lighting Committee of the Vestry have reported that the Vestry's electrical engineers had reported upon the tenders for machinery, and the report had been carefully considered in detail. The tenders for Section A included the engines, generators, and other plant required within the generating station Nine firms tendered, and the committee recommended the Vestry to accept the tender of the Electric Construction Company for Brush engines at the price of £12,079, subject to guarantees, the contractors to replace at their cost the Brush engines in the event of the same not working to the satisfaction of the engineers with Willans engines, at an extra cost to the Vestry of £2,800, being the price of these engines over the price of the Brush engines. Eventually the Vestry decided to have the Willans engines. It was then moved that the contract for Section B should be given to Crompton and Co. An amendment was moved that the contract go to the Electric Construction Company, whose price was only £18 more than Crompton's. The amendment was carried. The Electric Lighting Committee also reported that they had received six tenders for Section B (steam and exhaust pipes, boilers, pumps, and cast iron work.) The committee recommended the Vestry to accept the tender of the Thames Ironworks Company at £4,500. This was agreed to. For Section C (motor transformers required for the sub-stations) the committee received 13 tenders, the highest amounting to £6,288, and the lowest—that of the Electric Construction Company—to £2,890. The tender of the latter was accepted. Ten tenders were received for Section D (the accumulator battery), and it was decided to accept that of Messrs. Pritchetts and Gold at £610. The highest tender amounted to £1 150

Tunbridge Wells.—The Electric Lighting Committee reported at the meeting of the Town Council that it was decided to extend the electric lighting mains in Madeira-park as houses were built. It was decided that 16-c.p. instead of 8 c.p. incandescent lamps be placed in street lamps, at a charge of £4 per lamp per annum. The following report from Mr. Boot was presented: "I have pleasure in presenting a short report of the progress of the electricity supply undertaking since the opening of the works last autumn.

	No. of lamps exclusive of public lamps.	Units generated at works.
October 1, 1895	740	4,117
November 1, 1895	2,694	8,782
December 1, 1895	3,350	10,747
January 1 1896	4,330	13,853
February 1, 1896	5,506	15,894
March 1, 1896	6,001	12 561
April 1, 1896	7 024	11 091

The machinery is only capable of supplying energy to 4 000 lamps, but by forcing our boilers and engines and using all the spare plant, we have been able to cope with the demand successfully, and by next winter when the extensions have been completed, we shall be in a position to supply 13,000 lamps exclusive of the public street arcs. The larger the demand the cheaper we are able to produce the unit, and thus, when 13,000 lamps are supplied, a considerable profit per annum will be made. It therefore becomes the duty of those interested in the reduction of the rates to use their influence to obtain as many consumers as possible."

York.—In answer to Mr. Alderman Wragge, who asked at the meeting of the City Council what had been the cost of the preliminary enquiries in connection with the electric light, Mr. Alderman Rymer said the amount paid of the rates for this purpose

Digitized by Google

in the year 1890 was £52. 9s. 6d.; in 1891, £239. 19s. 4d.; in 1892, £53. 0s. 4d.; in 1893, £35. 13s. 1d., making a total of £381. 2s. 3d. Then there had been expended and placed to capital account to March 30, 1896, £110. 5s. paid to Prof. Kennedy, and a sum of £228. 3s., making with the amount already given a total of £609. 5s. 3d. That did not include the fee of 100 guineas to Prof. Kennedy for his present work. Mr. Lambert moved, "That the public debt of the city having reached approximately £500,000, owing chiefly to the extravagance of the School Board and the extraordinary cost of the new sewerage scheme (the estimated further expenditure on such scheme being at present an indefinite quantity), it is undesirable to enter upon any new scheme of a speculative character such as the adoption of an electric lighting system under municipal management or by means of municipal capital, and that the resolution passed by the Council, May 17, 1892 by which it was decided to keep the electric lighting of the city in the hands of the Corporation, be rescinded, together with any subsequent resolutions of this Council so far as such later resolutions commit this Council to any outlay of municipal moneys on the proposed undertaking." The motion was lost by 17 votes to 9. Mr. Alderman Rymer moved, "That it be an instruction to the Streets and Buildings Committee when they present their report on the electric lighting recommending a tender for acceptance, at the same time to furnish the Council with the probable number of ratepayers (founded on a canvass of the parts of the city proposed to be lighted) likely to use the light, and the number of lights they will probably require." This was seconded by Mr. Lambert, but lost by 17 votes to 14. At a meeting of churchwardens and overseers of the various York parishes a resolution was carried objecting to the scheme being undertaken by the Council.

Bath.—A special meeting of the Urban Sanitary Authority has been held to consider a report from the Electric Lighting Committee. This report recommended the Authority to accept Prof. Kennedy's valuation of the Bath electric light works, and to offer the company £24,533 as the price of their undertaking. A letter was received from the solicitor to the electric lighting company stating that, having regard to the report of Prof Kennedy, they were now prepared to accept the sum of £29 500, which amount was less than 15 years' purchase of the profit income of the concern. If the Corporation were unable to accept this proposal, the company asked that they would appoint representatives with full powers to meet the company's representatives at a meeting at the offices of the Board of Trade, as suggested by them in their letter of April 29. Alderman Sturges reminded the Authority that the company originally required £45,000 for the undertaking, a price which the Authority considered very high, while Mr. Hammond, acting for the Corporation, put it at £16,000. There was such a wide divergence of opinion between the company and the Corporation at the conference before the Board of Trade, that Sir Courtenay Boyle suggested revaluation by an independent valuer. Prof. Kennedy was appointed, and his valuation was, if he might describe it so, a sort of halfway house. His price was £22,733, and his valuation the committee, at their meeting on Saturday, were unanimous in accepting. They had always assured the company that they were desirous of dealing with them fairly Then there was an item for the land which was not included in the £22,733, or in Mr. Hammond's valuation of £16,000 After some little trouble they fixed upon Mr. Willcox, the county land surveyor, to make a valuation in respect to this item, which the company themselves valued at £2.000 and the price which Mr. Willcox fixed at £1,800 The committee were very distinct in recommending the purchase at the items of £22,733 and £1,800 Mr. Morris seconded the resolution, which was carried. It was also decided that a deputation should attend the Board of Trade offices, as suggested by the assistant secretary, and that the whole matter should be remitted to the committee with full power to settle and agree to the purchase of the undertaking on the basis of the recommendation contained in their report. At a meeting of the Sanitary Committee the Statutory Hospital Committee recommended that the hospital be lighted with gas, but in view of the prospect of the town becoming proprietor of the electric light works it was decided to defer the matter.

Brighton.—At the meeting of the Town Council the Lighting Committee reported that they had agreed on the sites for arc lamps to be erected in accordance with the report of the committee of January 6 last, except those it was proposed to place in Norfolk-road. It was resolved that two arc lamps be erected in Bedford-square instead of Norfolk-road. A letter was read from Mr. W. L. Madgen, enquiring if the Council would subscribe to the Municipal Electrical Association, and inviting the attendance of members of the committee at the first annual convention of the association to be held on June 10 11, and 12. It was resolved that the Council should subscribe a sum of £1 1s. annually to the Municipal Electrical Association, and that the chairman be requested to represent the Council at the convention. On the motion of Councillor Stafford these proceedings were agreed to. The Lighting Committee reported on tenders received for supplying and delivering cast-iron and drawn-steel bracket posts for suspending electric light arc lamps, and recommended the Council to accept the tender of Messrs. Hart, Son Peard, and Co., Limited, of Birmingham, to supply and deliver 80 posts in accordance with drawings and specifications prepared by the borough surveyor for £2,500 with a further price of £31. 5s for each additional post ordered. The tenders included one from Messrs C. S. Mallet and Co, of London, whose price was £1,880 for 80 and £24 each additional post (tender since withdrawn), and one from Messrs. Reed and Son, of Brighton, at £2,460 for 80 posts, and £30. 15s. per additional post. The committee also submitted tenders for supplying 100 double-carbon arc lamps, including the fixing of 95 of such lamps in standards erected in the borough, and recommended the acceptance of Messrs. Crompton and Co.'s tender at £2 200. Councillor Stafford, in moving the adoption of the recommendations of the committee in this report observed, as to the tenders for the lamp standards, that the committee had not selected the lowest tender—that of Messrs. Reed and Son—but recommended the acceptance of the tender of Messrs. Hart, Son, and Peard, whose tender was slightly more than that of Messrs. Reed. As to that, he wished to say the committee took this into their very careful consideration, and though they were unanimously of the opinion that they would like a local man to have the contract the committee were influenced in favour of Messrs. Hart Son, and Peard because they had been successful on the first occasion and had made the standards now existing in the town, and because it was very important that they should have these standards furnished by the end of August Messrs. Hart, Son, and Peard had all the plant and particulars, and having served the Corporation well the committee felt justified in offering them this contract. The committee had no feeling in the matter, and if the Council expressed a wish that they should accept the lowest tender they would be quite prepared to fall in with that wish, the Council taking the responsibility. Councillor Armes then proposed an exception that the tender of Messrs. Reed and Son be accepted. He believed Messrs. Reed and Son were as capable of carrying out this work as any Birmingham firm, and he held that, as far as possible, they ought to give their work to local tradesmen. Alderman Davey seconded. The exception was carried unanimously. The recommendations, as thus amended, were then agreed to.

County of London and Brush Provincial Electric Lighting Company, Limited.—This Company announce a second issue of £10,000 cumulative 6 per cent. preference shares at a premium of £2 per share, which are offered for subscription on behalf of the Company by the Electric and General Investment Company, Limited, 1 and 2, Great Winchester-street, E.C. The prospectus states that the present issue of 10,000 preference shares is made in order to provide funds for the further development of the Company's business, and, in allotting, applications received from registered holders of existing preference and ordinary shares of the Company will be preferentially considered. It is not intended that the balance of 20,000 preference shares shall be issued except at a higher premium than that at which the present issue is offered. The audited balance-sheet of the Company at December 31, 1895 shows capital expenditure as follows: county of London stations—land, buildings, machinery, plant, mains, etc., £137,065. 3s. 9d.; provincial stations—investments in and advances to associated electricity supply companies, £156,019. 4s. 2d.—total, £293,084. 7s. 11d. This figure has been increased by expenditure incurred since the above-mentioned date. Dividends at the full rate of 6 per cent. per annum have been paid on the existing preference shares for the year ended December 31, 1895, and the directors consider that the earnings of the Company during the present year will be sufficient to pay the dividends on the preference shares, including the present issue. The Company holds provisional orders, confirmed by Acts of Parliament, for the following districts in the county of London: the united parish of St. James and St. John, Clerkenwell; the parish of St. Luke, Middlesex; the district of the Wandsworth District Board of Works, including the parishes of Wandsworth, Putney, Clapham, Balham, Tooting, and Streatham; the parish of St. George-the-Martyr Southwark; and the district of the St Olave District Board of Works. In the St. Luke and Clerkenwell districts the whole of the street work in the compulsory areas has been completed, and the station buildings are far advanced. Applications have been received for the equivalent of 7,000 8 c.p lamps, of which 6,000 are connected to the Company's mains, and the directors anticipate that there will be a sufficient number of lamps applied for by the time the station is completed to ensure a profit being earned from the commencement of working the plant. In the Wandsworth district the cables are being drawn in, the transformer sub-stations are in course of construction, and the generating station on the River Wandle is making rapid progress. The plant now on order for the St Luke and Clerkenwell and Wandsworth stations will be capable of supplying 99,000 8-c.p lamps, and the buildings for these stations will be sufficiently large to accommodate plant of more than double this capacity. The Company have applied to the Board of Trade for a provisional order for other areas in South London, and an order has been granted for the parish of Camberwell, subject to confirmation by Parliament. With regard to the undertakings in the provinces in which the Company hold controlling interests, the station buildings at Bournemouth have been remodelled and enlarged, and considerable extensions of mains have been carried out within the past year, The plant is capable of supplying 27,500 8-c.p lamps, and connections equivalent to 21,000 8 c.p. lamps have been made. The Dover station was completed last year, and an uninterrupted supply of current has been given since April, 1895. The plant is capable of supplying 11,000 8-c.p lamps, and 5 800 8-c.p lamps are already conected. Considerable extensions of mains have been made during the past year, and further extensions are now in progress. The plant is capable of supplying 9,500 8-c.p lamps, and 5,900 are now connected The preference and ordinary shares already subscribed are quoted in the Stock Exchange official list, and in due course application will be made to include the present issue in the quotation. Prospectuses and forms of application can be obtained from the bankers, the brokers, the Electric and General Investment Company, Limited, and at the offices of the Company. The list of subscriptions opened yesterday and closes to-day (Friday).

PROVISIONAL PATENTS, 1896.

MAY 4.

9402 Improvement in electric gas-lighting devices. Oscar von Morstein, 89, Chancery-lane, London. (Complete specification.)

9447. Improved reversible variable speed gear applicable for use in electrical regulation and other purposes. Arthur George Cooke, 70, Chancery-lane, London.

20542A. Improvements in or connected with apparatus for the electrolytic decomposition of liquids. George Bell and George William Bell, 15, Water-street, Liverpool. (Date claimed under Patents Rule 19, October 31, 1895.)

MAY 5.

9480. Improvements in electrical contacting devices for subways or conduits. Alvaro S. Krotz, William P. Allen, and Oliver S Kelly, 5, John Dalton-street, Manchester. (Complete specification.)

9517. Improvements in electric locking and block signalling on railways. William Robert Sykes and Frederick Thomas Hollins, Liverpool street Station, London.

9528. Improvements in telegraphic relays and the like. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London (Charles G. Burke, United States.) (Complete specification.)

9530. Improvements in sockets or holders for incandescent electric lamps. James Devonshire, 70, Chancery-lane, London. (Herbert C. Wirt, United States) (Complete specification.)

9531. Improvements in dynamo-electric machines. James Devonshire, 70, Chancery-lane, London. (Charles P Steinmitz, United States.) (Complete specification.)

9534. Improvements in electric switches for use with or without mechanical or electromagnetic brakes. John Lavender. 23, Coleman-street, London.

9537. Improvements in or relating to electro-mechanically propelled vehicles. John Lavender, 23, Coleman-street, London.

9555. Improvements in or connected with electric burglar and other alarms. Thomas Alfred Clarke, 6, Lord-street, Liverpool.

9565. Improvements in or connected with electric melting apparatus. Martin Schindler, 46, Lincoln's-inn fields, London.

MAY 6.

9619. Improvements in incandescent electric lamps. Samuel Phillips Eastick and Egerton Sayer, 47, Ashford-road, Cricklewood, London.

9637. Improvements in arc lamps. Antoine Blahnik, 47, Lincoln's-inn-fields, London.

9650. Improvements in electromotors and dynamos and in apparatus for use therewith. Emil Lanhoffer, 322 High Holborn, London. (Complete specification.)

MAY 7.

9667. Electric arc lamps. William Fox, 4, Bramley-street, Broughton, Lancs.

9668. Electric arc lamps and projectors. William Fox, 4, Bramley-street, Broughton, Lancs.

9681. An improved method of street lighting by glow lamps Horace L. P Boot, The Town Hall, Tunbridge Wells, Kent.

9713. A signal indicator for use on locomotives and means for electrically operating the same. David Foulis, 115, St. Vincent-street, Glasgow.

9758. Improvements in floorcloths or carpets for the purpose of electrical distribution therein. Ferdinand Fanta, 1, Queen Victoria street, London.

MAY 8

9806. Improvements in apparatus or devices for starting and arresting electromotors employed in driving wire-drawing or other similar machines. Henry Pieper Fils, 47, Lincoln's-inn fields, London.

9817. Improved shade for use in connection with electric incandescent lamps and the like. Elizabeth Bach, Henry Sylvester Lewis, and Alick Boyd Saunders, *Invention* Office, Mitre-court, Fleet-street, London. (Complete specification.)

9820. Improvements in coupling boxes for electrical circuits. Max Binswanger and Francis George Bell, 73, St. Stephen's-road, Upton Park, London

9832. Improvements in telephone systems of exchange. John Edward Kingsbury, 24, Southampton buildings, Chancery-lane, London (The Western Electric Company, United States.)

9843. Improvements relating to electric current meters. Reginald Page Wilson, 70, Chancery-lane, London.

MAY 9.

9910. Improvements in secondary batteries. Alexander Schanschieff, 77, Chancery-lane, London.

9919. Improvements in and relating to exhausted tubes for electrical and other purposes. William Friese-Greene, 55, Chancery-lane, London.

9929. The self-returning electric bell indicator. Reginald W. Lane, 125, Denmark-hill, London.

SPECIFICATIONS PUBLISHED.

1887.

4664. Electric furnaces. Thompson. (E. H. and A. H. Cowles.) (Third edition.)

1890.

2504. Electrically propelling vehicles, etc. Wynne. (Second edition.)

1894.

9285 Electrodes. Kellner. (Second edition.)

15082. Magneto-electric machines for cycles, etc. Tilmann and Lexow. (Second edition.)

15276. Diaphragms for electrolytic purposes. Kiliani and others (Second edition.)

NOTES.

The Junior Engineers.—The Institution of Junior Engineers has arranged a visit to the Fowler-Waring cable works at North Woolwich on May 30.

Cable to Germany.—The new telegraphic cable between Germany and England is to start from Borkum, one of the Frisian islands, and land at Bacton, a village on the coast of Norfolk, between Yarmouth and Cromer.

Fatal Accident.—Last week a young man named Bates unfortunately made contact with his hand with a high-tension wire at the St. Mary's station of the Bedford Corporation electric lighting works, and received a shock which caused his death.

Meteorological Society.—At the last meeting of the Royal Meteorological Society, Mr. P. H. Curtis's paper on anemometers was taken. The conclusion arrived at was that for anemometrical records to be reliable and of value, not only must the instrument be exposed in an open place, free from local obstructions, but it is also absolutely essential that the stand which carries it shall offer practically no resistance to the wind. The instrument, for instance, should not be placed on the roof of a house.

Electrical Congress at Geneva.—The subjects to be discussed at the International Electrical Congress to be held at Geneva in connection with the Swiss National Exhibition are five in number—namely, magnetic units and their proper names, photometric units, long-distance transmission of power and the question of the employment of alternating or continuous currents for that purpose, the protection of high-tension lines from atmospheric discharges, and, lastly, the various troubles caused by electric tramways.

Northumberland-avenue.—On Monday the *Pall Mall Gazette* alarmed the town with a report of an electrical fire in Northumberland-avenue. Information as to the precise cause of the occurrence is not available, but it appears that what happened was that two wires in the County Council's subway heated and ignited some of the guttapercha insulation. There was naturally an amount of smoke and not a little smell, but nothing more serious resulted than the drawing out of a quantity of cable for inspection and repair and its subsequent replacement.

North-East Coast Engineers.—The programme of the summer visit of the North-East Coast Institution of Engineers to Cardiff, which is to take place on Tuesday, June 23, assigns that day to a visit to Newport and the Alexandra Dock, and a trip up the Usk; Wednesday is devoted to Cardiff Docks, the Dowlais Works, and the Cardiff Exhibition, with a smoking concert in the evening; on Thursday morning papers are to be read by Mr. J. F. Walliker and Mr. J. R. Fothergill, and the afternoon is given up to Barry; on Friday the meeting closes with a trip to Ilfracombe.

Lighthouse Communication.—It is stated that in consequence of the serious difficulties which continue to be experienced in maintaining electrical communications with certain light-vessels on the system now employed, the Royal Commission on Electrical Communication with Lighthouses and Light-Vessels have decided to postpone their final report until attempts have been made to overcome them. Meanwhile they have presented an interim report, which states that, as far as the lighthouses are concerned, the cables which have been laid on their recommendation have worked satisfactorily.

A New Cell.—A new cell is described in *L'Electricien*, the main feature of which is the short distance between the plates. It is a carbon-zinc combination. The carbon is channelled down one side and filled in with a paste made of powdered carbon and manganese dioxide. The zinc plate is amalgamated in the usual way, but is only separated from the carbon by a piece of coarse felt of small thickness. The liquid is a solution of two parts by weight of sal-ammoniac to one part each of common salt and chloride of zinc. It is stated that a cell about 6½in. high will give four amperes at 1·5 volts, but nothing is said as to the duration.

The Moscow Coronation.—According to the *St. Petersburger Zeitung*, the coronation of the Czar at Moscow is to be the occasion of a good deal of electric lighting. Besides the lighting of the Kremlin Palace, barracks, arsenal, etc., the Ivan Veliki bell tower is to be illuminated, or rather has already been so, since a trial illumination was made on the occasion of the Russian Easter. From telegrams to the daily papers, it appears that the house frontage of the principal streets of Moscow is almost entirely concealed by flags, garlands, and electric lamps, and decorative devices, while the rehearsals of the electrical illuminations have collected large crowds.

Movable Lightning Conductor.—According to the *Centralblatt der Bauverwaltung*, Mr. E. Hommert, of Coburg, has gone to the trouble of inventing and patenting a movable top for lightning conductors. A tube with a pulley is rigged on the top of the chimney shaft or building to be protected, and the top, which is weighted to keep it upright, is hauled up and down by a wire passing over the pulley and through the tube. If, therefore, there are in Germany or elsewhere any persons who would like to be constantly hauling their lightning conductors up and down, and, perhaps, of substituting ones of superior quality and appearance on Sundays and holidays, their wants can be supplied.

Lord Kelvin on Lamps.—Lord Kelvin has been giving evidence before the House of Commons Committee on the question of the Petroleum Acts in connection with the public safety. He thinks the sale of paraffin for ordinary use of a lower flashing point than 130deg., open test, ought to be prohibited by law, but does not think it would be wise to introduce legislative restrictions on the manufacture and sale of lamps. In fact, so far as the petroleum lamp is concerned, he despairs of introducing safety by legislation. It seems that the most dangerous lamps are not in poor houses but in fine drawing-rooms. Some of those on tall stands with large crystal reservoirs would make a very bad accident if they fell over. On a balance of evils, Lord Kelvin prefers metal to glass reservoirs, but jokingly suggested that the ideal would be an aluminium reservoir with a Röntgen ray to see inside of it.

The Hæmostat.—Demonstrations have been given lately by Mr. Lawson Tait of his electric hæmostat, an instrument which, as the name denotes, is intended for the arrest of bleeding in surgical operations. A platinum wire, arranged to carry a current, is enclosed in the blades of a pair of steel forceps, or any other requisite instrument, the wire being isolated by a bed of burnt pipeclay. A current of suitable voltage is turned on, the artery seized and compressed, and in a few seconds the tissues and arterial walls are so agglutinated that the passage of blood is rendered impossible. The temperature employed is about 180deg. F., so that it will be seen that the principle is fundamentally different from that of electrical cauterising instruments. It is stated that by Mr. Tait's instrument the necessity for a ligature is removed, and a new and completely effective

Digitized by Google

method is placed in the hands of the surgeon for the treatment of surface oozing.

Motorcart Legislation.—The Bill for legalising motorcarts has got through the committee stage in the Lords. In the committee on Tuesday night, Lord Harris moved to amend Clause 1 by substituting four tons for two as the maximum weight of unladen vehicles exempted from enactments restricting the use of locomotives on highways. Lord Thring agreed, but suggested that some limit should be placed on the load that the vehicle might carry; and the Earl of Kimberley said that as many improvements would be made in the development of these vehicles, power should be given to make by-laws to meet unexpected changes and inventions. Lord Harris said it would be ridiculous to expect carriages carrying persons to be weighed whenever a policeman or someone else demanded it. But he asked their lordships to accept the Bill now, as he was not empowered by Mr. Chaplin to accept any suggestions at present for further amendments in the Bill. The amendment was then agreed to, and after some further debate the Bill passed the committee.

Portable Lighting Plant.—An article in the *Elektrotechnischer Anzeiger* is devoted to the subject of portable electric lighting plant, and in particular to the type manufactured by Messrs. C. and E. Fein, of Stuttgart. Two illustrations are given. In the first, a vertical boiler, engine, and a dynamo directly coupled to it, are arranged longitudinally on a rectangular iron frame carrying the wheels. The latter look somewhat small if the machine is to be taken far over rough country. The form of the vertical boiler is that of a truncated cone with the smaller end downwards, probably to bring it within the longitudinal limits of the frame. In a larger type of plant, a horizontal boiler is adopted, with a single-cylinder engine above it, on the plan of the ordinary portable engine. The dynamo is carried in front on a heavy bracket bolted on to the smoke-box, and is driven from the flywheel by a leather belt. Both engines have a somewhat curious look to the eyes of anyone accustomed to the forms of English designs, and this unusual appearance is not lessened by the presence of a feed-water heater in the larger of the two engines.

Erratum.—We regret that a laughable mistake was made in our last week's note headed "Units"—"the temperature of melting ice" being printed as "the temperature of melting glass." One of our esteemed contemporaries, in carefully looking through our columns in search of the Institution debate for abstraction, discovered the mistake and has kindly pointed it out to us. We regret that the Institution debate was crowded out by the account of the Dublin tramways, and hence that the absent president takes credit for Prof. Ayrton's remarks in our contemporary's columns. Before seeing the gentle reminder in our contemporary we had written the following: Accidents happen in the best regulated journals, and hasty writing caused a decidedly absurd slip in these columns last week, from which it appeared that the French Government wanted people to use as a standard the resistance of a column of mercury measured "at the temperature of melting glass." Infallibility is the last thing claimed by the writer of these notes, and as all our readers know that the substance whose melting point fixes the temperature of 0deg. C. is not glass, it is to be presumed no one troubled to speculate how such a remarkable measurement is to be made.

The University of London.—The correspondence on the London University question continues in the *Times*. Sir George Young contributes a letter which is absolutely unintelligible to anyone who has not the report of the commission at his side. He, however, does not agree with Prof. Ramsay, denies—under conditions—the "practical unanimity," and wants to have done with "phrase-making.' Mr. T. B. Napier goes further, and says that "in the University of London there is an overwhelming consensus of opinion against the recommendations of the commissioners," while Dr. W. J. Collins remarks that "the consensus of opinion, which is held to be so remarkable, appears to be chiefly limited to a desire for forcibly throwing the university into the melting pot without having taken the trouble to form any very clear ideas as to the sort of thing it is hoped will eventually emerge therefrom," and adds that the support of University College was only secured on the understanding that under the new scheme all examinations are intended to be, unless otherwise specially ordered, different for external and internal students. All of which shows the extreme difficulty of trying to be two different things at the same time—viz., what is usually implied by the term university and what is quite a different thing—namely, an examining board for the British Empire.

Motorcarts.—There are some people who are unkind enough to say that oil-driven motorcarts smell and shake. It is satisfactory to learn from the statement of a director at the meeting of the Daimler Motor Company on Tuesday that it is not so. "When you go along the little smell that there is is left behind you." It seems a pity that the vibration cannot be left behind in the same way. Moreover, it is added that "when you see the car standing still you form an absolutely wrong conclusion as to both the smell and vibration." It must be remembered that it is one of the interesting peculiarities of the oil motorcart that, although the cart is stopped, the engine keeps on going just the same. It is doubtless unreasonable, but, all the same, people who will put up with a certain amount of irregular shaking while they are going will object entirely to a regular and steady vibration while they are stopping still. Although many persons have supposed that horses are about to be entirely superseded by motorcarts, it is believed that up to the present the "noble animal" has not realised it. But at Eastbourne on Tuesday, where a couple of motorcarts were a feature in the procession in connection with the battle of flowers, behind one of them there sorrowfully walked a horse clothed in a rug bearing the inscription "R. I. P." It is sincerely to be hoped in the interest of the horse that that particular motorcart was not one of those that "leave their smell behind them."

Carbon and Permeability.—In his paper read before the Institution of Civil Engineers on "Magnetic Data of Iron and Steel," Mr. H. F. Parshall remarked that a study of the results of magnetic tests and their comparison with those of the chemical analysis showed a more or less intimate relationship according to the degree with which the modifying physical conditions might be controlled. In general, a greater degree of purity was an indication of high permeability, but as the different qualities of iron and steel merged into each other by insensible degrees, owing to variations in the processes of manufacture, chemical analysis might be taken only as an approximate indication of the magnetic properties. Carbon was the most important element entering into the composition of commercial iron, and, within the limits that chemical analysis might serve as an indication of the physical structure, the permeability was inversely as the amount of carbon present. The limitation as to the state of physical structure was greatly affected by the state of the carbon, that is, whether free or combined; in cast iron, as well as in steel, the effect of graphite was second

Digitized by Google

to that of the carbide, commonly known as fixed or combined carbon. Beyond a certain degree of purity, as in wrought iron and carbon steels, the treatment as to annealing and tempering became of first importance. The magnetic properties of some of the alloys of iron, nickel, or manganese were such as to show that the physical structure was the ultimate determining factor. The hysteresis loss was, in general, inversely as the degree of purity, but in comparatively pure irons it was determined principally by its treatment as to annealing, heating, and mechanical straining.

Production of Three-Phase Currents.—Mr. E. Hospitalier has called attention in *L'Industrie Electrique* to a system devised by Messrs. Galileo Ferrari and Riccardo Arnò by which a high-tension alternating current is transformed into a low-tension alternating current in the usual way for lighting purposes, or, if wanted, into three or polyphased currents for power as the circumstances of the case may require, and which it is believed will prove convenient where it is desired to introduce motors on a distribution system originally intended for lighting only. The main point is the adoption of a new kind of rotary transformer, which, while performing the ordinary function of reducing the voltage, also shifts the phase of the induced current by a quarter period. For this purpose two fixed coils and a rotating armature are used. A transformer of the ordinary type, of course, is used to give the other phase. Without endeavouring to detract from the originality of Messrs. Ferrari and Arnò's plan, Mr. Hospitalier calls attention to the communication made as far back as 1894 to the Société française de Physique in which Mr. A. Potier proposed to obtain diphase or triphase currents from a transformer with a rotating armature that was practically an alternating-current motor with additional coils. In this case, however, the rotary transformer alone was sufficient. The whole subject is one that has engaged attention both on this side of the Atlantic and in America. There are obviously many more ways than one of obtaining the end desired. A good deal more practical work will have to be done before it is determined when and in what way it is desirable to work triphase or polyphase motors from an alternating system, and until then questions of priority may very well stand over.

Fuses Again.—They are still discussing the fuse question in America, where they seem to expect a very great deal more from fuses than they are likely to get in this world of imperfect appliances. The San Francisco *Journal of Electricity* makes some remarks on the subject which may be worth reproducing. "On beginning an examination of the numerous investigations which have been made on the subject," says our contemporary, "it will be noticed that the usage of fuse wires for protecting electric circuits seems to have been materially changed from the purposes to which they were designed by those proportioning them in the early history of the art. When the fuse wire was originally adopted it was intended to protect the conducting wire of the circuit from being overheated, and at that time it was well understood that the fuse could not be expected to protect the machinery installed upon the circuit; in every instance the fuse was adjusted to the carrying capacity of the wire which it was to protect. All of the recent studies of the fuse-wire question have turned upon their ability to protect machinery attached to the conducting circuit, and while in the first case the amount of energy passing over the fuse before its temperature reached the melting point determined its size, in the more recent investigations of the fuses the criterion of quality has been assumed to be the value of the current necessary to melt the fuse. Why the extensive experiments that have been performed on the basis of this second hypothesis should have been necessary is an exceedingly difficult question to answer, for the reason that anyone examining the conditions necessary for raising a given piece of metal to its melting point by the means of the passage of an electric current will at once find that the melting point is a time function of the energy, and in consequence cannot be stated in terms of current. Nothing further than a confirmation of this theoretical deduction has been derived from the experiments performed."

Another Large Power Plant Completed.—The General Electric Company, of New York, have just handed over to the owners the works in connection with the Folsom-Sacramento scheme. The electric plant consists of four 750-kilowatt three-phase generators direct coupled to 1,250-h.p. turbines of McCormick type, with horizontal shafts. The alternators have 24 poles, which, when running at a speed of 300 revolutions, give a frequency of 60 complete cycles per second. The voltage at the generator is 800. From the generators the current passes to the switchboards and thence to nine step-up transformers in the upper storey of the power-house. The capacity of each transformer is 250 kilowatts when cooled by an air-blast. In this transformation the pressure is raised from 800 volts to 11,000 volts, at which pressure the current passes to the high-tension lines, by which it is transmitted from Folsom to Sacramento. The distance is about 24 miles. The pole line is double throughout, and each pole carries two cross-arms for two circuits. Each circuit consists of three bare copper wires supported on double-petticoated porcelain insulators. Each circuit can carry the output of one alternator, and any alternator can be thrown on any line. The line loss when transmitting 3,000 h.p. is calculated at 7·5 per cent. A telephone line is carried on the same poles as the main-line wires. These latter are, however, spiraled every mile and the telephone wires are transposed every fifth pole, which is said to nullify the induction effects. At Sacramento the current is again transformed down. The largest consumer at present supplied is the Sacramento street railway, which takes current for 32 motorcars and trailers, running on 24½ miles of single and 17 miles of double track. The current for this work is supplied at 500 volts by machines somewhat similar in design to that used on the Dublin-Dalkey lines, described fully in our columns last week. The water-power works from which the water to drive the turbines is obtained are fully described in the *Electrical Journal*, from which paper we take the above data.

Frequency.—The tendency of the American engineers to endorse the Continental practice of using low frequencies with alternate-current work is well brought out in a series of articles now running in the *Electrical World*. We have always advocated the same course, and hence are pleased to publish the returns of the General Electric Company, of New York, who use low frequencies. All the old single-phase generators designed by this firm were for 125 cycles per second, but the latest types are designed for 60 cycles. There is no reason why motors cannot be operated on circuits of any frequency, but in order to get them comparatively small, and at the same time adapted to low speeds, frequencies lower than 125 must be adopted. The drop in the line is another factor of great importance. The reactance voltage—that is, the drop due to self-induction of the line—is directly proportional to the frequency, and consequently with twice the frequency there is twice the reactive drop. The total drop—that is, the impedance drop—is the square root of the square of the ohmic drop plus

Digitized by Google

the square of the reactive drop, and consequently the total drop n the line is greatly increased as the reactive drop increases. From what has just been said it would appear that low frequencies are preferable, but transformers used on low-frequency circuits are necessarily larger for the same output than those required when higher frequencies are employed. Consequently, a mean between the two must be chosen, the higher frequencies being avoided, owing to the greater drop in the line and the necessarily high speed of generators and motors, while it is practically impossible to operate incandescent lights below 25 to 30 cycles per second, and arc lights below 40 to 45 cycles, owing to the perceptible flickering. It is chiefly for these reasons that the General Electric Company has adopted 60 cycles as a standard. But in special cases, as, for instance, in transforming alternating currents to continuous currents, it is advisable to use still lower frequencies, as otherwise the peripheral speed and the number of poles of the rotary transformers have to be high. An instance of this will be found in the South Dublin tramways, described in our last week's issue, where a frequency of 30 was adopted by Mr. Parshall for the three-phase power transmission work.

A Wonderful Bicycle.—There are various reasons which—other things, such as cost and weight, being equal—would lead one to prefer an electric to an oil or steam motorcart, but we never hoped to hear of anything a quarter as good as the machine to be described below. It is nothing less than an electric bicycle which will defy competition on the part of steam, oil, or any other source of power whatever. The invention, of course, comes from America, and equally, of course, is enthusiastically described in the non-technical Press — in this particular case the New York *Sunday World* is responsible — but the description has been extensively copied. It appears that the inventor, Mr. J. O'Brien, takes a wheel (American for bicycle) weighing 27lb., and adds "a battery, motor, and switchboard, which together bring the weight up to 60lb." From the illustration, the battery, which we are told is a "dry chloride" one, appears rather larger than a cigar box, and the size of the motor is not worth mentioning. With this equipment we are told that "a force can be maintained which will carry the bicycle over rough country roads, up hill and down hill, for a period of 48 hours." Only those who have seen an American "rough country road" know what this really means. In fact, "the speed of the electric bicycle is practically unlimited. It has been tested up to nearly 50 miles an hour, faster than which no one dared to try it." There is, however, power to spare, for one of the features of the machine is an electric head lamp. As, however, the light-giving power of this is stated in feet instead of candles, it is not easy to ascertain exactly how much surplus energy there is available for illuminating purposes. The inventor is an electrical engineer of experience. At any rate, "he has patented machines for preventing collisions at sea, automatic ice-boxes, scintillating signs, and nickel-in-the-slot machines. He considers the battery which operates the electric bicycle his greatest achievement." When we have seen it do all the above we shall consider so too. With every possible deference to the authority and accuracy of our New York contemporary, it would have been more satisfactory if it had been stated that some member of its staff had seen the bicycle run for half an hour or so, say, at 10 miles an hour instead of 50. At present, even with the liberal discount of 80 per cent., Mr. O'Brien's invention will have some difficulty in gaining acceptance in electrical circles.

Contacts with Tram Wires.—In the course of an article in the *Elektrotechnische Zeitschrift* of May 7 on the subject of safety appliances for preventing any injurious effect following the accidental contact between overhead tramway wires and telegraph or telephone wires, Mr. R. Ulbricht figures and describes an automatic apparatus for immediately earthing the tramwire in case of such a contact. The apparatus has been tried by Mr. Melzer, of the Zwickau tramways, and exhibited in action on that line in the presence of representatives of the Imperial German Post Office and of both the Leipzig tramway companies. The trolley wires of the up and down lines of the tramways, where they are crossed by telephone or telegraph wires, are protected by guard wires running parallel to the trolley wires and at some distance above them. In most cases of fallen wire this would be sufficient to prevent a contact, as the fallen wire would hang in bights from the guard wires and would be well clear of the trolley wires. If, however, the breakage occurred close overhead so that there was a loose end to be dealt with, this would not be the case, since the loose end would hang straight down from the guard wire to the tram wire, and if it fused there is nothing to determine at which point it would go. Moreover, under the influence of the wind or anything causing the loose end to swing, there would be the contingency of momentary contacts occurring of a very troublesome character. In the Zwickau arrangement the two guard wires are connected by a cross span wire which goes to the coil of an electromagnet and thence to the rails, constituting the return of the tramway circuit. A wire also goes from the overhead tram wire to this, the earthing wire, at some point between the electromagnet and the rails. This wire, of course, puts the trolley wire to earth, and the circuit is accordingly broken in the neighbourhood of the electromagnet. When, however, the latter is excited and attracts its armature, this latter releases a falling piece, which completes the circuit. Any slight current from the telegraph or telephone wire would be too weak to affect the armature, but even a momentary contact, which sends the heavy current of the tram wire through the short length of fallen wire to the guard wire and thence to the electromagnet, at once puts the tram wire to earth until someone comes along and replaces the falling piece. It is stated that the trials made at Zwickau proved exceedingly satisfactory.

Magnetic Testing of Iron.—In a paper read before the Institution of Civil Engineers on "The Magnetic Testing of Iron and Steel," Prof. J. A. Ewing, F.R.S., referred to the practical importance which now attaches to the magnetic testing of iron and steel in relation to the manufacture of dynamos and transformers. From being a mere laboratory experiment interesting only to students of physics it had passed into the rank of an engineering operation. In dynamo construction the introduction of permeable steel castings for the field magnets had given greater latitude as to form without loss of efficiency, the best steel castings being indeed somewhat better magnetically than most forged iron. In stampings of sheet metal for transformers the main consideration was absence of hysteresis, and so great had been the advance in this respect that iron was now readily obtainable with only half the amount of hysteresis which was considered possible a few years ago. This had brought about a notable increase in the efficiency of alternate-current distribution by reducing the large element of loss which occurred through the hysteresis of transformer cores during the hours of light load as well as of heavy load. A novel apparatus was shown in detail for measuring permeability by comparing the magnetising force required to produce a given induction with the force required to produce equal induction in a standard bar. This apparatus, which the author terms a magnetic bridge,

Digitized by Google

from its analogy to the Wheatstone bridge for the measurement of resistance, reduced the operation of testing to a comparison between the specimen and a bar the magnetic quality of which had been determined once for all by the instrument maker. The two bars were connected by end yokes, and by varying the number of turns in the magnetising coil on one of them the yokes were brought to the same magnetic potential. The relative number of turns on the two thus gave the relative magnetising forces required to produce the same induction in both. A simple form of magnetic detector showed when the two yokes were brought to the same potential. The manipulation consisted in varying the number of turns acting on one bar by means of dial switches, while the magnetising current was from time to time reversed. This permeability tester was intended for workshop use, and might take its place alongside of the author's hysteresis tester, which was also described. The methods of directly measuring hysteresis were briefly referred to.

Vacuum Tube Lamps.—Mr. D. McFarlan Moore has been reading a paper before the American Institution of Electrical Engineers on the subject of recent developments in vacuum tube lighting. This is what is sometimes called in America—as it seems to us without any justification—"etheric" lighting. Mr. Moore's chief invention in this connection is, as is well known, the use of a make-and-break enclosed in a vacuum tube instead of one working in the open air. By this means he obtains a much sharper cut-off and avoids the effects of the arc that follows the attempt to break any considerable current in air. To obtain the maximum amount of glow in the vacuum tube Mr. Moore finds it advisable to largely increase the surface of one of the terminals, one of the forms used by him consisting of a perfect brush of loops of aluminium wire. So much has been heard lately of the cathode rays that no one will be surprised to learn that it is the negative terminal only which is enlarged and subdivided. Beyond the new forms of terminals experimented with, there is little that is novel n the paper. The question naturally asked on a matter of this kind is, What is the efficiency of the method compared with an ordinary incandescent lamp? So far as can be gathered, Mr. Moore appears to consider on theoretical grounds that the possible efficiency ought to be very high since there are few or no useless "heat" waves. This does not at all follow, for ordinary ultra-violet and Röntgen waves consume energy, but are quite as useless for lighting purposes as the infra-red "heat" waves. Practically, all we get on the subject of efficiency is contained in the following: "It is interesting to contrast the colour of the light of these tubes with that of an incandescent lamp. The reddish and wasteful glare of the latter, indicating heat waves, and the pure daylight white of the former are immediately apparent. It is this difference in colour that makes an efficiency calculation so difficult. It is very easy to ask the question, How many watts per candle-power? But in most instances it indicates a lack of information on the part of the questioner. The question should be, How many watts per amount of light equivalent to one candle-power? But even this is not perfectly correct, because it is well-nigh impossible to compare accurately lights of a different colour and power of diffusion. When the use the light is to be put to is stated, the problem is much more simple. For instance, if it is to be used to read by, the range of legibility can be made the basis of comparison between the true incandescent lamp and the candle." Until he gets something much more definite than this, even with the addition of the somewhat obvious statement that an increased illumination "can be reached by multiplying the area and length of the tubes and distributing them in the most advantageous manner," it is to be feared that the "questioner," in his lack of information, will be inclined to think that the carbon filament is not at present in much danger of being superseded by Mr. Moore's modified Geissler tube.

Medical Electricity.—An abstract of a paper on the subject of the scope and value of electricity in medicine which was read before the Medical Society of the London Hospital by Dr. W. S. Hedley has been published in the *Lancet*. Dr. Hedley had naturally something to say on the subject of Röntgen photographs, and then went on to speak of the convenience of being able to obtain a limitless supply of current from the electric lighting main. In the lead of a 16-c.p. lamp there is "an ever-ready supply of electrical energy, either of a continuous or of an alternating kind. The former furnishes a current which will do all that the uniform flow of the galvanic cell can accomplish. Passing the same current through a coil, there is obtained that dissymmetrical alternating current universally familiar as the current of the medical induction apparatus." Still availing himself of the same supply, the medical man can heat his cautery, light an exploring lamp, or charge his accumulators, or, passing the current through a motor, drive his static machine or actuate his therapeutic alternator. The latter can in its turn be arranged to supply a current having all the smoothness and other qualities of that known as sinusoidal, with its rapidity, its E.M.F., and even the shape of its E.M.F. curve under absolute control. "If the current that comes to his door in the street mains be an alternating one, he passes it through a transformer to apply it to the body to electrise his water bath or to heat his cautery. He is thus supplied with an alternating current of a symmetrical, although not of a strictly sinusoidal, character, whose therapeutic usefulness is fully proved. In that form of oscillating current known as the 'static-induced' he finds another modern current and the most efficient method of inducing powerful and painless muscular contraction. Still more recently he begins to turn his attention to those currents of great frequency and high potential whose phenomena are a revelation to the scientific mind, and whose effects open out new fields of physiological research and point to endless therapeutic possibilities." Not very long ago, when an unmeasured current was "dabbed" on to the body at the end of a couple of sponges, and it was orthodox practice to administer faradaic torture by means of a couple of metal cylinders grasped by the patient, the one end and aim of electrisation was to induce muscular contraction. This idea still survived in the popular mind, in the electricity of the "trained nurse" and of the "medical electrician." Modern practice covered a far wider field. Besides a purely localised action, nutritive, sedative, or stimulant, it was sought by methods of general electrisation, not only to influence for good the functional activity of organs, but to exercise a demonstrable, perhaps even a measurable, influence on the whole process of nutrition. After referring to the curious fact that when the frequency became exceedingly high (over 100,000 ⌒ per second), the effect of the alternating current was completely changed, so that the human body might be placed in circuit almost without the patient knowing it, Dr. Hedley concluded by speaking of the investigations of Mr. d'Arsonval on the physiological effects of such currents, which appear to be an analgesia at the point of entry and exit of the current; a fall of arterial tension; increased action of the skin; and an increase in the "respiratory combustions." This naturally led to a reference to Mr. d'Arsonval's researches on the electrical attenuation of toxines, a subject which has already been treated of in these columns.

LECTURE XXXI.

(Specially Contributed.)

Mr. Robert Davidson constructed an electromagnetic locomotive which was tried upon the Edinburgh and Glasgow Railway in 1842. Fig. 1 shows the general arrangement. Here the fixed magnets were electro-magnets, and the rotating magnets on the large cylinders geared to the wheels were permanent magnets.

I am afraid I have wasted a little time in indicating these applications, but I do it with a purpose to show how eager in those very early days men were to apply electrical energy to industrial purposes. They failed, not because

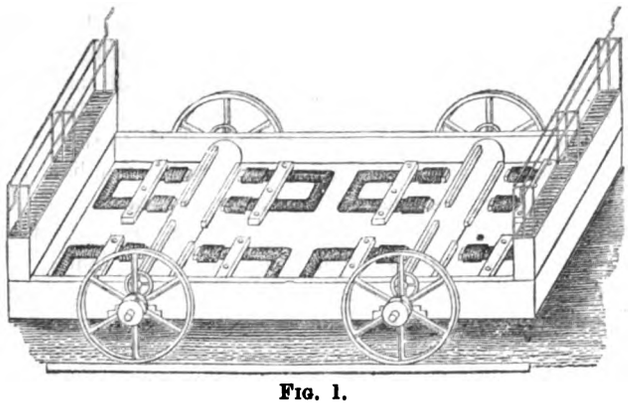

FIG. 1.

their machines were cumbrous or complicated, but because energy obtained by burning zinc in a battery was far too costly to compete against energy obtained from other sources. The application of Faraday's researches was for a time almost entirely directed towards the obtaining a means to transform electrical into mechanical energy—that is, to obtain a workable motor. The end of this period may fitly be said to have been about the time of the great exhibition of 1851. At that exhibition a medal was awarded to Mr. Hjorth, a Dane, for his motor.

Hjorth's Machine.—The diagrams (Fig. 2) show this machine in elevation and section, which, it will be seen,

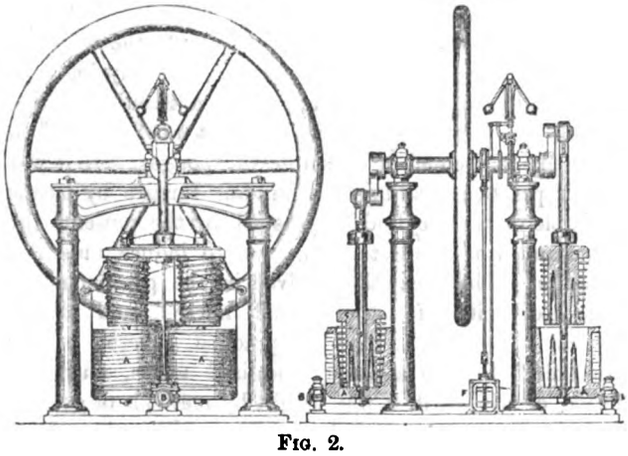

FIG. 2.

differs considerably in appearance from those previously mentioned. A A is a hollow horseshoe magnet conical on the inside, and suspended so that it oscillates on the centre, B. In the interior of this magnet is fixed a number of conical rods of different lengths. C C, above A A, is another horseshoe magnet conical on the outside, with apertures in the core corresponding to the before-mentioned conical rods. This upper magnet moves on guide rods connected together at the top by a cross-head, and fastened at the bottom of the magnet, A A. A connecting rod attached to the centre of C C drives a flywheel shaft by cranks in the usual way. A commutator, O, working like the slide-valve of a steam-engine, was used. The current to the commutator was regulated by a flywheel. The current from battery goes by commutator to coils of A A, thence to coils of C C, and back to battery. It will be seen that Soren Hjorth was attempting to fashion a motor on the lines of the steam-engine. According to the report of the exhibition, "the following table shows the attractive power" of a particular dimensioned machine:

Distance of the respective poles (inches)	The attractive force was (lbs.)
5	72
4	80
3	98
1½	140

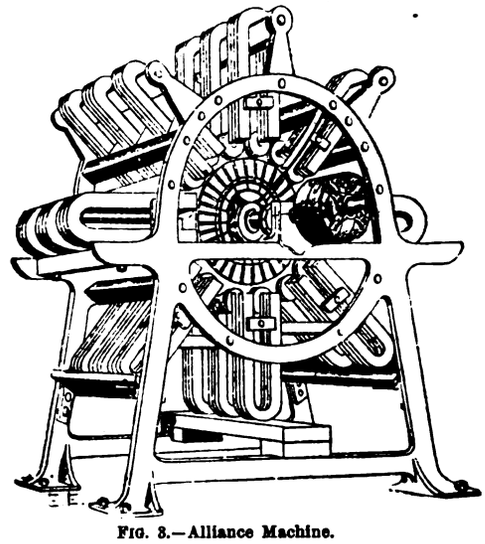

FIG. 3.—Alliance Machine.

Lighthouse Work.—From the earliest years of the century it had been known that an electric current passing between carbon points gave rise to an extremely brilliant light. Inventors were desirous of designing electric machines which would enable this light to be used in light-

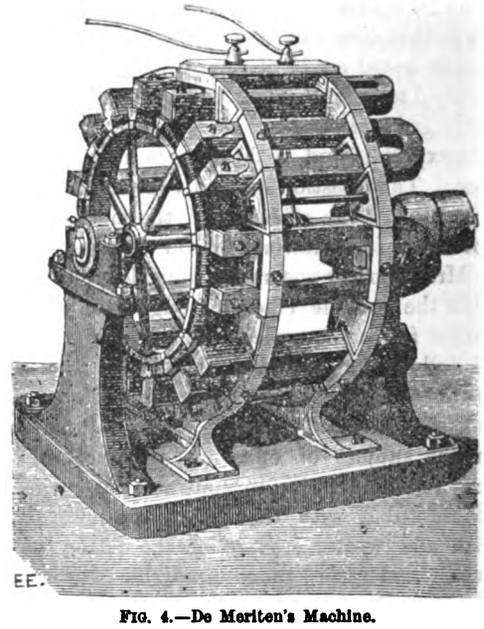

FIG. 4.—De Meriten's Machine.

house work, and ultimately they succeeded. I will direct attention to two such machines only—one almost the first designed for lighthouses, the other almost the last. Prof. Nollet, of Brussels, suggested, and the Compagnie d'Alliance, of Paris, built, magneto machines of the kind illustrated in Fig. 3. In these Alliance machines an armature rotates between eight rows of compound permanent magnets. This is merely a multiple modification of Clarke. The armature coils are double in number to the magnets, and can be connected in different ways according as greater pressure or greater current is required. Fig. 4 shows the De Meritens machine, the field of which is also made of compound permanent magnets. The armature is in shape like a wheel, on the rim of which are the coils. Fig. 5 shows the construction of the coils. Each is wound round a core of laminated soft

Digitized by Google

iron, and fixed on the rim of the wheel, as shown. But we need spend little more time over this class of machine. They have no substantial advantages to place against their obvious disadvantages. Practically their advantages are two :

(1) The E.M.F. is proportional to the velocity of rotation ; and
(2) is independent of external excitation.

They have the enormous disadvantages—

(1) That the field density is far less when using permanent magnets than can be obtained by using electromagnets ; hence
(2) to obtain similar results from the use of permanent magnets, the machines must be very much larger than when electromagnets are used.

These considerations have led to the almost universal adoption of dynamos in engineering work, though for the

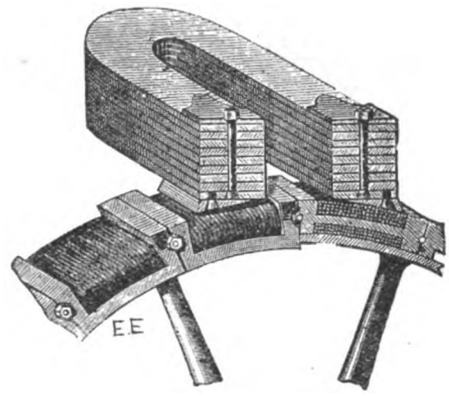

FIG. 5.—Coils and Magnet of De Meriten's Machine.

very minor but important purpose of telephonic signalling small magnetos are largely used.

EXPERIMENTAL TESTS ON THE INFLUENCE OF THE SHAPE OF THE APPLIED POTENTIAL DIFFERENCE WAVE ON THE IRON LOSSES OF TRANSFORMERS.*

BY STANLEY BEETON, C. PERCY TAYLOR (STUDENTS), AND JAMES MARK BARR.

(Concluded from page 552.)

Power Curve.—The actual mean power supplied to the transformer was determined by finding the products of corresponding instantaneous values of the applied P.D. and current. The products thus found were plotted as curves (see Figs. 2, 4, 5, 6, 7, 8, 9, and 10), which were then integrated with a planimeter and the mean ordinate determined. This then gave us the input, and, since the copper loss was negligible—being less than one-fifth of a watt—it represented with sufficient accuracy for our purpose the total watts lost in the iron core of the transformer.

EFFECTS OF THE INJECTOR.

As this paper is essentially one dealing with transformer tests, we do not propose to discuss at any length the effects obtained by the use of the injector, but it may be useful to consider one typical case of injected resistance and one of capacity. The effect of injecting rather a large resistance when the current is not in phase with the P.D. maintained between the terminals of the transformer is well illustrated by the wave shown in Fig. 7. In this test, a resistance of 36 ohms was thrown in over the first part of the wave, but, in addition, we had a capacity of 96 microfarads permanently in the main circuit, which brought the current into phase with the P.D. between the terminals of the alternator. By bringing the current into phase with the P.D. we mean that the zero readings of the two waves occurred at the same point, but the waves, of course, possessed very different shapes. The distinguishing feature of this wave is the curious sort of hump which occurs just at the beginning. The explanation of this is not hard to find. It will be observed that during the interval in which the current is opposite in sign to the P.D. the ordinates of the latter curve tend to increase, but directly the current-wave crosses the zero line the P.D. begins to decrease.

* Abstract of paper read before the Institution of Electrical Engineers, May 14.

Consider for a moment the instantaneous P.D.'s between the terminals (1) of the machine and condenser, (2) of the injector, (3) of the transformer and resistance, R, represented by v_1, v_2, v_3 (Fig. 11) respectively, during the interval just alluded to.

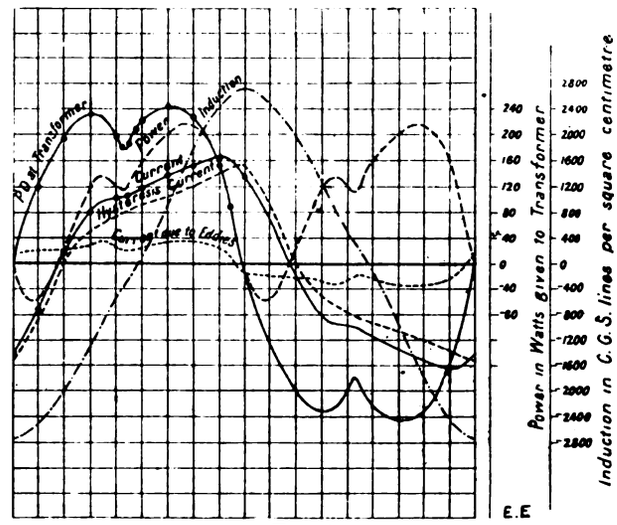

FIG. 4.

Since the current is in the opposite direction to the terminal P.D. of the transformer, we have :

$$v_1 = v_3 - v_2 ;$$
$$v_3 = v_1 + v_2 ;$$

that is to say, for this short interval the P.D. across the transformer equals the sum of the P.D.'s of the machine and the injector. This, then, fully accounts for the presence of the

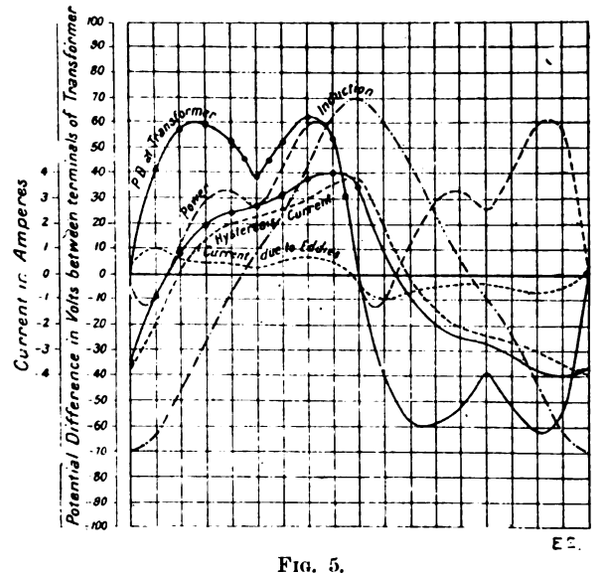

FIG. 5.

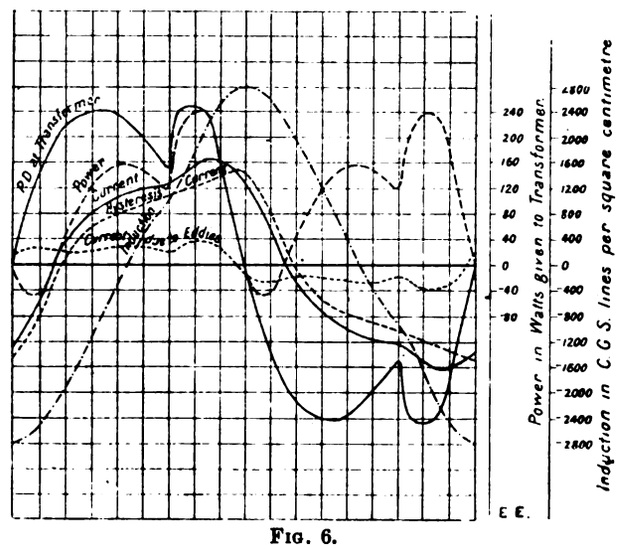

FIG. 6.

hump. The effects obtained by the injection of capacity will be best explained by a reference to Fig. 12 and Fig. 13. In the latter

Digitized by Google

we have shown (Curve A) a P.D. wave at the terminals of the transformer and non-inductive resistance, R (Fig. 12). This was obtained by adding, at each point, the drop in pressure due to this resistance to a curve obtained at the terminals of the transformer, and shown in Fig. 5. The interval during which the condenser (60 microfarads) was in circuit is also shown in Fig. 13, and the curve of P.D. between its terminals—*i.e.*, the brushes, b_1 b_2, Fig. I.—marked B, was obtained by integrating the current-wave during this interval. By combining these two waves we get the P.D. between the terminals of the alternator, shown in Curve C. Since the condenser P.D. is obtained by integration, its maximum necessarily occurs when

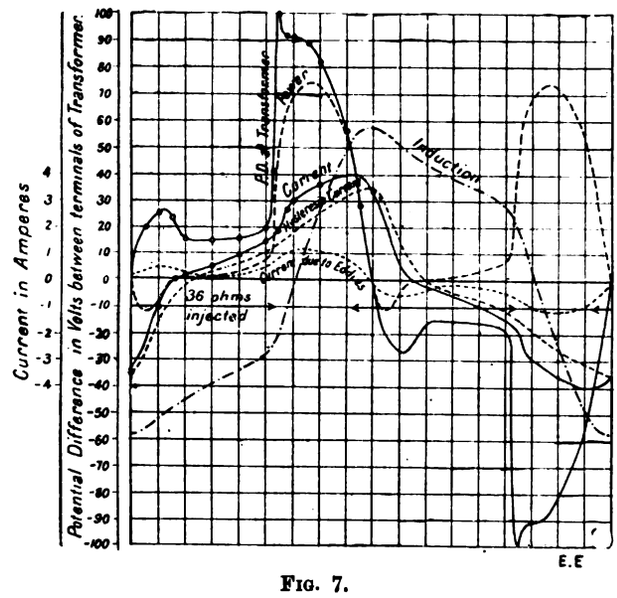

FIG. 7.

the current crosses the zero line. This maximum value is directly proportional to the area of the current-curve from the point of injection to its zero point, and inversely proportional to the capacity of the condensers injected.

On referring to Fig. 13, we note that since the current is large when the condenser is thrown into circuit, the Curve B rises very rapidly, and therefore the Curve A turns down very rapidly away from Curve C, and crosses the zero line where B and C cross each other. The maximum point of the condenser P.D. curve, of course, occurs at the same time

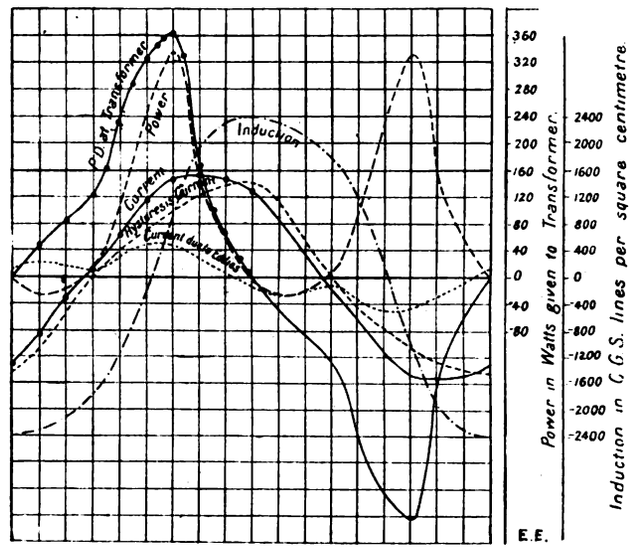

FIG. 8.

as the maximum difference between Curves A and C, and thus, when the Curve B turns down, A bends over and begins to approach C, which it crosses when B crosses the zero line. Soon after this the condenser is short-circuited, and thus B follows the zero line and A is again coincident with the alternator P.D. curve, C. This coincidence lasts as long as the condenser is cut out of circuit by the "injector." The points marked on the condenser potential difference curve, B, were obtained by experiment. They do not lie accurately on the curve, but this is probably due to slight sparking at the injector brushes, which made the electrometer readings somewhat unsteady when taking this wave. Our chief object in taking points on this curve was to set at rest any fears that might have been entertained as to the advisability of periodically throwing in and removing from a circuit a bank of condensers. It has been shown that when a circuit possessing capacity in the form of condensers is broken there may be a sudden rise of potential at the terminals of the latter. No such rise of P.D. was observed in our experiments, and this was due to the fact that the condenser circuit was never really broken, for the capacity was removed from the circuit by being short-circuited.

Discussion of Results.

Our great aim at the time of carrying out these experiments was to find some definite law connecting the iron loss in the

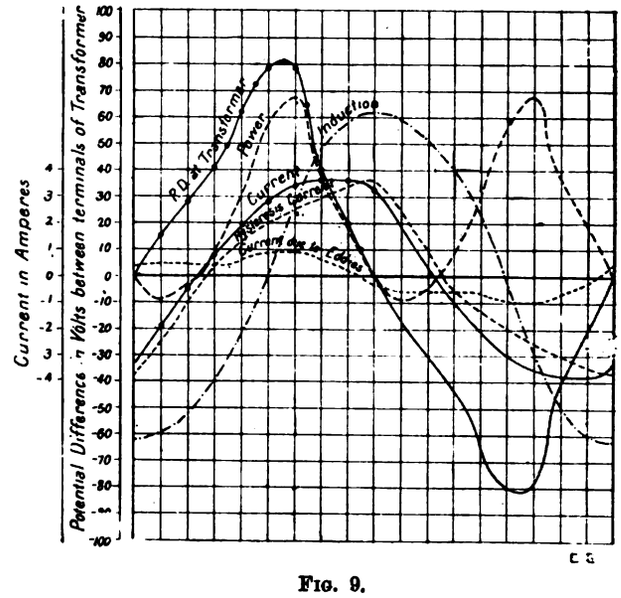

FIG. 9.

transformer with the shape of the applied P.D. wave. In no work published on the subject at that time could we find any results or conclusions which could form the basis of a connected theory regarding this question. None of the investigations on this subject had justified any conclusion which could materially help in judging of the exact, or even relative, value of wave-forms not actually tried.

The conclusions that we came to were—(1) That if the R.M.S. value of the applied P.D. is constant, and the area of the P.D. wave is constant, then, whatever be the shape of this wave, the

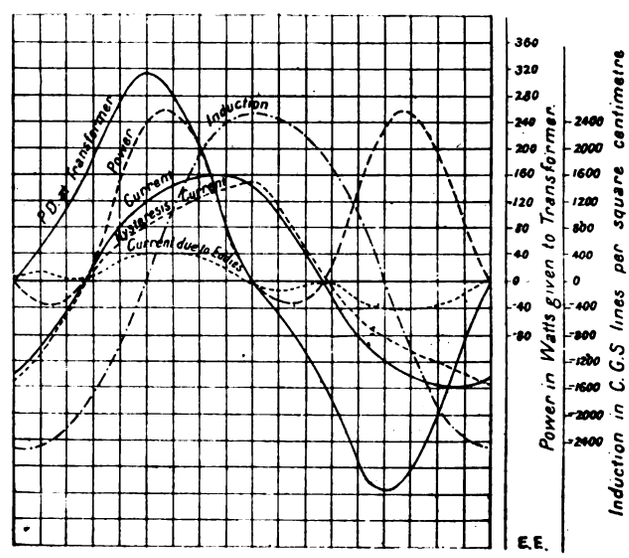

FIG. 10.

total iron loss cannot vary. (2) That if the R.M.S. value of the applied P.D. is constant, but the area of the P.D. wave varies, then, whatever be the shape of this wave, the total iron loss will vary by an amount which is only dependent upon the area of the P.D. wave. We feel fully justified in coming to these conclusions, for, as we have shown above, the hysteresis loss depends only on the area of the P.D. wave, and we have proved experimentally that the eddy-current loss is constant for a given effective P.D. This we refer to again below. The results calculated from our tests will be found in as concise a form as possible in Table I.

Hysteresis Tests.—In order to get a complete theory regarding the iron losses it was essential that we should separate those due

Digitized by Google

to hysteresis and to eddy currents. To determine the former loss, then, hysteresis tests were made on the transformer itself by a method independently suggested and used by Prof. Ewing* and Dr. Hopkinson. We found this method most satisfactory. The two 12-turn coils of the transformer were used, one as the magnetising and the other as the test coil. A large resistance was put in series with the magnetising coil to reduce the time constant of the circuit. The magnetising current was measured by means of a standard Weston ammeter, while in series with the test coil we had an Ayrton and Mather narrow-coil ballistic galvanometer, which was standardised with one of Hibbert's magnetic standards. In this way four complete B H cycles, as shown in Fig. 14, were determined for the transformer.

They were integrated with an Amsler polar planimeter, and the results obtained were plotted to show the relation between the maximum induction and power lost in hysteresis, at a frequency of 100 ∽. The curve is shown in Fig. 15. The hysteresis loss for each test was obtained by calculating the maximum induction as previously shown, and referring to this curve, and the eddy-current loss by subtracting this from the total.

Variation of Applied P.D.—It will be observed, on reference to Table I., that the effective values of the applied potential difference are not all the same; they vary between 48 and 50

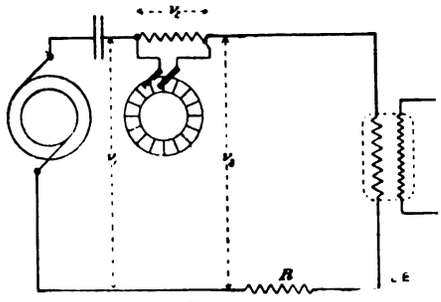

FIG. 11.

volts. This is due to the fact that they are not instrument readings, but are calculated from the curves by means of the first moment planimeter. The method of using this instrument to give the R.M.S. value of a curve was described in the articles referred to elsewhere. It was due originally to Mr. Turner, one of the demonstrators in the mathematical department of the Central Technical College. We have given preference to this method of obtaining the effective values of both P.D. and current mainly for two reasons—viz.: Firstly, far greater accuracy is attainable by this method. This is easily understood when it is remembered that, by increasing the number of water cells used in conjunction with the electrometer, this instrument could be made as sensitive as we wanted, whereas the sensibility of the voltmeter was fixed. Secondly, by calculating all results from the curves of P.D. and current, any small errors which arise from inaccurate readings or drawing appear in them all, and these are made of far less relative importance. The voltmeter, V (Fig. 1), was therefore only used to keep the effective value of the P.D. constant throughout each test, and it was not specially calibrated. This

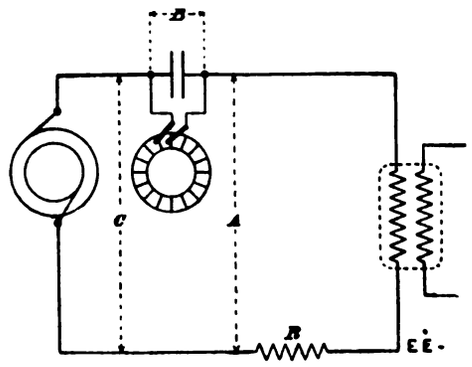

FIG. 12.

method of calculating the results has, however, introduced some difficulty in drawing conclusions from our experiments, as the small variations in effective P.D. must be taken into consideration. The difficulty of arriving at the true effect of this variation arises mainly from the fact that the eddy-current loss has been obtained by taking the difference of two much larger quantities, and thus the probable error is a large percentage of the whole range of variation. After a careful study of columns 2 and 7 of Table I., we came to the conclusion that within the limits of accuracy attainable by our experiments—*i.e.*, about

* Paper on "Magnetic Qualities of Iron," Royal Society, April, 1894.

½ per cent.—the eddy-current loss is proportional to the square of the applied P.D. This leads at once to the further conclusion that the eddy-current loss is independent of the wave-form of P.D. so long as its R.M.S. value is constant. In order that this variation of applied P.D. should not obscure the true meaning of our results, we have calculated by known laws the difference in the iron losses produced by the difference in the value of the applied P.D. from 50 volts, and thus found the iron losses for each wave shape corresponding to an applied P.D. of 50 volts. The methods of correction employed were as follows: The effect of variations in the R.M.S. value of the P.D. is most marked in the case of the eddy-current loss, so that we will deal with this first. We have, then, here corrected the eddy-current loss to a value corresponding to a common effective applied P.D. of 50 volts. In doing this, since each test is corrected separately, we only assume that so long as the

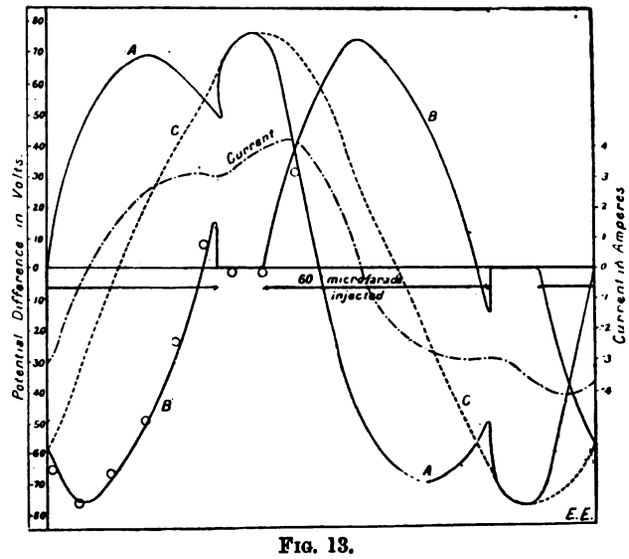

FIG. 13.

wave shape of P.D. is constant the eddy-current loss varies as the square of the effective volts.

From Table II. we see that, with the exception of the tests shown in Fig. 5 and Fig. 9, the eddy-current loss is practically constant; the variation of half a watt meaning only ½ per cent. in the determination of the total loss. Again, for the correction of the hysteresis loss we need only consider laws which hold so long as the wave-form is constant. Under these circumstances the area of the P.D. wave varies directly as the R.M.S. value. Now, the area gives us at once the maximum induction, and the corrected hysteresis loss is then got by a further reference to Fig. 15. The values thus obtained are given in column 4 of Table II. The corrected total loss is now

Digitized by Google

determined by the addition of the eddy-current and hysteresis losses, from which we obtain the curve given in Fig. 16.

The Relation of the Iron Losses to the Area of the P.D. Wave.—In Fig. 16 we have shown the relation between the total power lost in the transformer and the area of the P.D. wave expressed as a percentage of the maximum area possible with the given R.M.S. value of 50 volts. It may be of interest to point out here that the ratio of the area of the P.D. wave

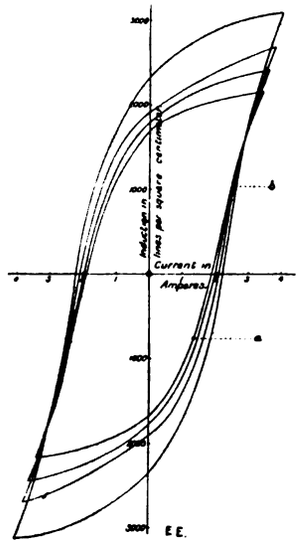

FIG. 14.

to its maximum possible value is the reciprocal of the ratio more recently called by Dr. Fleming the "form-factor." This maximum area occurs with the rectangular shape shown in Fig. 17. Such a rectangular wave would give the greatest possible value of maximum induction—in this case 3,020 lines per square centimetre. On reference to Fig. 15, it will be found that the loss due to hysteresis corresponding to this value of maximum induction would be 88 watts; adding to this the constant loss due to eddy currents—namely, 33 watts—the total power wasted in the iron comes out at 121 watts. This value must, of course, constitute the top limit of the curve shown in Fig. 16, since this wave shape has the largest area possible with the given effective value. It will be noticed that we have gone fairly close to the limit in this direction in our experiments. The process of fixing the limit in the other direction consists of finding the shape of P.D. wave which will have the smallest area for the given effective value. Now, it will be obvious that before the area of a wave of constant R.M.S. valve can be very much diminished the maximum ordinate must of necessity be increased. We cannot, therefore, diminish to any great extent the hysteresis loss without necessitating

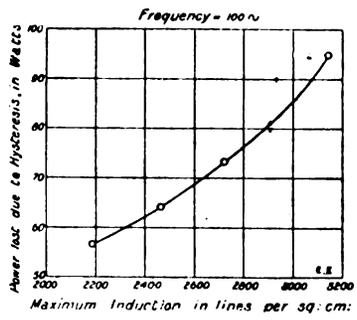

FIG. 15.—Curve showing the Relation between the Maximum Induction and Power Lost in Hysteresis in a 3-K.W. Mordey Transformer.

higher insulation. If, on account of this difficulty, the maximum ordinate of the P.D. wave must have a definite limit (*e.g.*, maximum value not to exceed twice the effective value), the shape giving the least iron loss will be that shown in Fig. 18. This is again rectangular, which may seem curious, but the essential point is to get as wide a peak as possible, and thus, as it were, confine the wave to one part of the period. This wave has been drawn to the same scale as the one given in Fig. 17. The area of the curve shown in Fig. 18 will be found to be exactly 50 per cent. of the possible maximum (Fig. 17); in fact, with waves of this type having a constant R.M.S. value, the area, and therefore the maximum induction, is inversely proportional to the maximum ordinate. This gives us a measure of the minimum possible hysteresis loss with different allowable P D. maxima. It is evident that unless the maximum ordinate of the wave is limited its area can be infinitely reduced while its R.M.S. value remains constant.

Advantages of Peaked Waves of P.D.—Our lowest iron loss is that given by the P.D. curve shown in Fig. 7. This is due to the fact that it approaches most closely to the form shown in Fig. 18, thus giving the least area, and consequently the smallest hysteresis loss. It will be observed from Table II. that there is a total variation of 22½ per cent. in the total iron losses. The consequent economy of using peaked waves of P.D. of course becomes especially noticeable at low loads, but even at full load the saving thus effected is by no means insignificant. For let us assume that the efficiency of a transformer worked off the P.D. wave shown in Fig. 6 is 95 per cent. at full load, then, if the iron loss is, say, 2½ per cent. of the maximum output, we would increase the efficiency

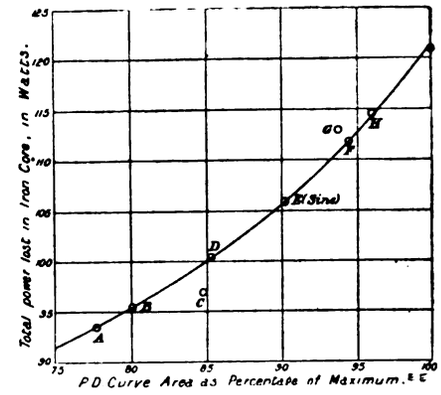

FIG. 16.—Curve showing Relation between the Total Power Lost in the Iron Core of a Transformer, and the Area of the Applied Potential Difference Wave expressed as Percentage of the Maximum Area possible with a R.M.S. value of 50 Volts. The letters A to H refer to the curves given in Figs. 2, 4, 5, 6, 7, 8, 9, 10.

of the transformer to over 95½ per cent. by using the P.D. wave shown in Fig. 9. Under circumstances of cheap power production this saving may not be of extreme importance, but in systems of distribution or transmission of power where large transformers are used, the efficiency of transformation is not the only question to be considered. One of the chief difficulties in designing large transformers is the providing of adequate means for keeping them cool, and any means by which the necessity for special cooling arrangements can be materially reduced will be sure to commend itself to those who have to deal with large transformers.

No-Load Current.

We have not been able to arrive at any satisfactory explanation of the variation of the no-load current with the shape of the applied P.D. wave. The curve given in Fig. 19, however, is interesting as showing that the maximum current occurs with the sine wave of P.D. The power factor for this wave (Fig. 2) is also the smallest (Table I.). This is a distinct point against the use of sine waves of P.D. with transformers, especially in cases where many transformers have to be kept magnetised on

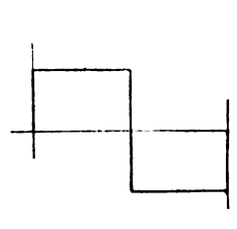

FIG. 17.—Type of the Least Efficient Wave of P.D. Maximum Value = Effective Value.

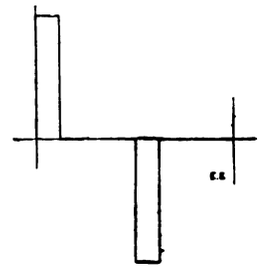

FIG. 18.—Type of the Most Efficient Wave of P.D. when the Maximum Value = 2 × Effective Value. (Same scale and effective value as in Fig. 17.)

light secondary load at the end of long mains; in cases such as these, the mains losses—which vary as the square of the current—form a very appreciable item of the whole loss. The difference between the R.M.S. currents in Fig. 7 and Fig. 2, for instance, is 25 per cent., so that the main losses in Fig. 2 would be more than 50 per cent. greater than in Fig. 7.

In order to arrive at a satisfactory explanation of the shapes of the current waves, they must be considered as built up of two components—a hysteresis component and an eddy-current component. We have split them up in this way in Figs. 4 to 10; the hysteresis component was obtained from the induction curve by means of the B H curves in Fig. 14, and the eddy current by taking the difference between this and the total current curve. It will be at once apparent that the peculiarities of the current curves are due almost entirely to the eddy-current component; the hysteresis parts are all very similar in shape. The roundness of the curves, especially

Digitized by Google

noticeable in Figs. 8, 9, and 10, is entirely due to the eddy currents, the hysteresis component being in all cases comparatively flat on both sides. The eddy-current components have been obtained by a somewhat complex method, and a discussion on the details of each one is therefore hardly justifiable; but as a class they exhibit some very interesting features, the most notable of which is that the curves are very nearly in phase with the P.D. waves. Speaking generally, the curves also have shapes similar to the P.D. waves. This is a clear indication of the fact that the eddy currents may be considered as equivalent to one current flowing in a supposed secondary circuit. It follows from this that the eddy currents have the effect of bringing the total primary current curve more nearly into phase with the P.D. wave, and thus tend to increase the power factor. It will be noticed that in all the curves, with the exception of Fig. 2, the eddy-current component leads

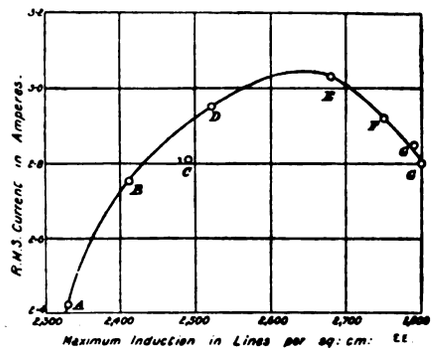

FIG. 19.—Curve showing the Relation between Maximum Induction and R.M.S. Current in a 3-K.W. Mordey Transformer. (From Table I.)

slightly in front of the P.D. wave; it is, however, so slight that it needs some corroboration from other experiments. The only explanation possible seems to be that the plates of the core, being separated by insulating paper, form a condenser, thus causing a small capacity current as well as the ordinary eddy currents.

NOTES ON INVESTIGATION BY DR. ROESSLER.

The conclusions at which we arrived in August were partly anticipated, we found, by Dr. Roessler in a paper read in Germany in July, 1895, but not published in England until November. Dr. Roessler, however, since he could only experiment with two wave-forms of applied P.D., could not prove by experiments the results which he obtained theoretically. Dr. Roessler's system of measurement differs very materially from ours. To obtain the power given to the transformer Dr. Roessler employed the usual form of dynamometer-wattmeter, with its necessary corrections, and this gave rise to some rather complex calculations with the different currents. Dr. Roessler treats the question very largely from a mathematical standpoint,

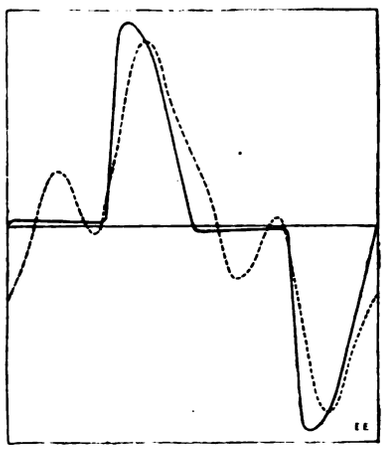

FIG. 20.—The Continuous Line Curve shows Wave actually Produced with Injector. The Dotted Line Curve shows Wave that would be produced by combining the First Three Odd Harmonics.

and introduces a correcting factor into his formulæ for each typical wave-shape; but he does not appear to have fully appreciated the fact that the whole question of hysteresis loss is wrapt up in the area of the applied P.D. wave, independently of the R.M.S. value. In this paper we have shown that it is this area alone which determines the hysteresis loss of a transformer. Dr. Roessler makes some interesting comments on the equation,

$$E p_1 = J_1 \omega_1 + 0{\cdot}4\pi \frac{n_1^2}{l} S \frac{d B}{d H} \frac{d J_1}{d t},$$

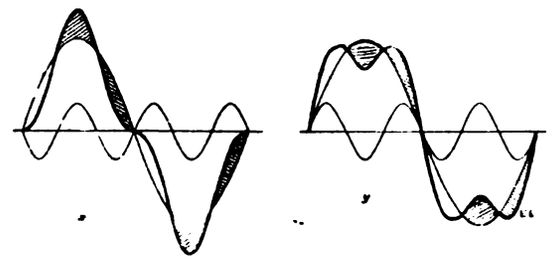
in which E p_1 = primary P.D., J = primary current (both instantaneous values), n = primary turns, and l and S are respectively the length and cross-section of the path of the lines in the iron.

The following sentence occurs: "If . . . the alternator gives a very pointed potential curve, and very high maximum value, the maximum value of $\frac{d B}{d H}\frac{d J_1}{d t}$ must be very great. *But* $\frac{d B}{d H}$ *is independent of the alternate-current curve*" [the italics are ours], "and only depends on the hysteresis curve; hence the value of $\frac{d J_1}{d t}$, which is simultaneous with the maximum value of the potential curve, must be greater with pointed curves than with flat." This is not necessarily so, and the reason is this—that the value of $\frac{d B}{d H}$ is dependent on the form of the P.D. curve in so much as it is dependent on the point on the hysteresis cycle at which we are working, and this, again, on the part of the period at which the maximum value of P.D. occurs. Compare Figs. 7 and 8. In Fig. 7, when the P.D. is at its maximum, the induction curve has not crossed the zero line, and we are working at the point marked "*a*," Fig. 14; but when the P.D. is a maximum in Fig. 8 we are working at the point "*b*," Fig. 14: the value of $\frac{d B}{d H}$ at *b* is 70 per cent. greater than at *a*, and this is why the current curve is so steep at the time of maximum P.D. in Fig. 7 and comparatively flat in Fig. 8, although the maximum P.D.'s in these two only differ by 10 per cent. The steepness of the curve in Fig. 7 is also partly due to the eddy currents. In conclusion, we wish to thank both Prof. Ayrton and Mr. Mather for their kindness and help throughout these experiments; and we are especially grateful to Prof. Ayrton for the assistance he has rendered us in the preparation of this paper.

APPENDIX.

Before deciding on the method described in this paper for obtaining potential difference waves of any desired shapes, we considered the practicability of using a series of alternators coupled on one shaft. By this means various component harmonics differing in phase, amplitude, and frequency could be produced and combined to give any desired wave-shape. This idea of combining harmonics to obtain prescribed results has been known for some time. Lord Kelvin used it in his famous tide-predictor, and it was afterwards employed by Profs. Ayrton and Perry in 1877 in their apparatus described in a paper on "The Music of Colour and Visible Motion."* Although this method would have been in some ways very convenient, we were obliged to dismiss it as too expensive. It is also difficult to get waves of very great irregularity by this method. Dr. Fleming, in reference to this method, remarked that three such alternators, giving frequencies in the ratio 1, 3, 5, would be sufficient for the majority of curves met with in practice. We were anxious, however, to experiment with waves not actually met with in practice, since our aim was not so much to find out which alternator now on the market was the best, but rather to give some information if possible which might be a guide in the future design of alternators for use on transformers.

On considering the question more fully, we also find that the first three odd harmonics given by the series of alternators just mentioned would not, in many cases of not very distorted waves, give a close approximation to the true shape; thus, we find that in order to get a peak in one part of a wave, it is necessary to cause the rest of the period to consist of a



Third Harmonic in anti-phase. Third Harmonic in co-phase.
FIG. 21.

series of irregular undulations. We cannot, in fact, by this method alter one part of the wave without getting into difficulties with the rest of it. This point is brought out very clearly in Fig. 20. Here we show a wave which we have produced by our method of "injection," and also the wave given by the combination of its first three odd harmonics (dotted curve). It will be noticed that though this wave approaches the desired shape at the peaked part, it is far from it during the rest of the period. The harmonics for this wave were obtained with one of Coradi's harmonic analysers, by the courtesy of Prof. Henrici. It is here that our method

* Physical Society, November 23, 1878.

Digitized by Google

has one of its chief advantages. If we want a peak or a depression in one part of our wave, we make it, and leave the rest in peace. The injector method is also one which may be adopted at very little cost. It may be argued that the condensers are expensive, but they are not necessary, as a great variety of waves can be got by injecting resistance and using more than one pair of brushes (b_1, b_2, Fig. 1), and so getting more than one injection on each half-wave. It should also be remembered that when using condensers the greatest effect is got with the least capacity. The effect of higher harmonics on the area of a P.D. wave (and consequently on the maximum induction) cannot be stated generally; but it may be of interest to indicate the general principles on which it rests. To do this, a simple case may be taken as an example. It is only necessary to consider odd harmonics, as even ones makes the waves unsymmetrical about the time line.

Consider the case of a third harmonic superimposed on a fundamental sine wave, as shown in Fig. 21. The amplitude of the harmonic is here three-tenths of that of the fundamental.* The two extreme cases are shown—namely, those with the harmonic in co- and anti- phase. The effective value of the resultant is the same in each case—viz., very nearly 4 per cent. greater than that of the fundamental—but in x the area of the semi-wave is diminished by that of a half period of the harmonic, and in z it is increased by the same amount; this is the maximum effect possible, since, whatever the relative phases be, two of the half periods of the harmonic cancel as regards area. The area of the wave may therefore be diminished or increased by 10 per cent. by the addition of the harmonic. The area of a sine wave of the same effective value as the resultants will be 4 per cent. greater than that of the original fundamental. Thus, by building up a wave of two harmonics such as here chosen, we may get resultants of constant effective value having areas from 6 per cent. greater to 13·5 per cent. less than that of the sine wave of that effective value. It will be apparent from this reasoning that the effect of harmonics is entirely dependent on their phase relatively to the fundamental, and that attempts such as were made at the time of the "Sine Wave Controversy" to state generally the effect of harmonics in the P.D. wave on the iron loss of a transformer are quite futile.

Discussion.

The paper was read for the joint authors by **Mr. C. Percy Taylor**, and in order to allow time for discussion portions of it were either summarised or omitted, while for convenience of demonstration other parts were transposed. Among the omitted parts was the note on Dr. Roessler's investigations. It will be seen that this was not without its effect on the discussion, but had any other course been adopted the latter must necessarily have been most seriously curtailed.

The first speaker was **Prof. Fleming**, who wished to correct some opinions which had been attributed to him in the paper. He (Prof. Fleming) would also like to make the criticism that the authors had not done enough justice to Dr. Roessler's work. Six months ago Dr. Roessler had described experiments which practically covered the whole of the conclusions the authors had arrived at. Dr. Roessler pointed out distinctly that the loss in transformers depended on the relation between the R.M.S. value and the true mean value, and the conclusions of the authors were only another way of saying the same thing. As his hearers all knew, he himself had found it convenient in this connection to define and use the term "form factor." Everyone knew before that the form of the curve had a good deal to do with the core loss in transformers, and that a peaked curve gave the least loss. The authors seemed to imply in the paper that he (Prof. Fleming) had thought that the sine curve gave the greatest loss. He knew very well it did nothing of the sort. He had only pointed out that machines with a sine curve did not give the least loss as at one time some had supposed. Again, the authors seemed to minimise the value of experiments made with actual machines in an endeavour to find the best alternator. Now, there was no best alternator outside of the manufacturer's catalogue. Each type had its own advantages. In order to improve any apparatus surely the first step was to know what the present form of it could achieve, and therefore the first thing to do in an investigation of this sort was to analyse the performance of existing well-known machines. That was what Dr. Roessler had done with two well-known machines, and he (Prof. Fleming) had done the same thing with the Ferranti, the Mordey, and the Thomson-Houston machines. Everyone was well aware that good design was really a compromise, and the adoption of one firm or another was really a question of the end in view. It had been well understood for a long time that a peaked curve gave a smaller loss than some other forms, and if he were asked to do so any manufacturer would give you a machine with a curve as sharp as a serpent's tooth. But then the secondary drop would be increased and the maximum value would be increased. In the City of London station, for instance, there were two machines which gave the same R.M.S. value, but which had a difference of 1,000 volts in their maximum values. To carry things to an extreme, there could be no particular advantage in designing and using a machine that would break down half the cables every time it was switched on. His own feeling was that a great deal could not be done in the direction of altering the curve. They could diminish hysteresis loss by giving a peaked form to the curve, but they would in doing so introduce other difficulties. Again, it was a common idea that any given alternating current machine had a fixed wave-form of its own. That was not the case—the wave-form depended on the load carried and on the armature reaction. There was nothing to be gained by the discovery that an extravagant form of curve would have unusual advantages in the way of smaller core loss. He thought that there was much more to be gained by studying the transformer than by confining their attention to the ideal curve form. What was badly wanted at the present time was the discovery of some means of reducing the increase in the loss in transformers that went on with time. There was no doubt, however, that in the mechanism described the authors had provided a means of arbitrarily varying the form of the wave. There was, nevertheless, no question that with the wave-forms which were met with in practice the first three terms (the odd harmonics) were enough to build up the curve while they were not enough when the wave-form was extreme. If the authors had been able to make curves which had different form factors, but the same R.M.S. value, it would have been interesting to have seen whether the form-factor was strictly proportional to the loss or merely increased with it. If the authors, with the appliances at their command, had done this, they would have added to the knowledge of the subject.

Mr. Rhodes remarked that, with relation to what Dr. Fleming had said, the subject might be attacked from a theoretical point of view. The transformers being on open secondary circuit, the potential difference between the terminals might be considered the same as the back E.M.F. Then, writing down the equation for the induced E.M.F., Mr. Rhodes ultimately arrived at a result that the iron loss depended on the area of the P.D. curves and not on their form, provided the virtual value of the P.D. is kept constant. With regard to the problem of making this loss as small as possible, though it had been said that it was not a practical one, he thought there might be cases in which it would be advisable to have the iron losses as small as possible, and therefore to know how to minimise them. If, however, they attempted to work out the problem by making $\int V\,dt$ a minimum, keeping $\int V^2\,dt$ constant, it would be found that there was no absolute minimum value unless the maximum P.D. was limited. If, however, the maximum P.D. was limited, there was a limiting value.

Mr. Evershed said he had come to the conclusion that it would not be advantageous to design machines which should differ very much from those at present in use, but that that was so did not in the least detract from the value of the experiments carried out by the authors of the paper. The theory of the alternating-current machine had been wrapped up in mystery and entangled with the sine wave, and Dr. Fleming had been responsible for much of that. Consequently, experiments of the kind carried out by the authors were very desirable. What was wanted to be known was the answer to the question, "How many units am I going to save if I alter all my machinery?" There were central stations in London which delivered three or four million units per annum. Assuming the transformers were banked, it remained to consider what could be the possible saving. Taking the figures in the paper as to the difference in the iron losses with different wave-forms, it would be found that if for the existing machines giving approximately sine waves some machine which gave a better form of wave—say some form approaching that given in Fig. 12 of the paper—the maximum saving appeared to be 10 per cent. of the 2½ per cent., which was the loss in the iron. On 4,000,000 units that gave a saving of 10,000 units. Those units saved, however, could not be charged at the selling price per unit, because all that was really saved was the coal required to generate them and a little oil and waste. If they put that at 1d. per unit there would be a maximum saving of 10,000 pennies, or less than £42 per annum. He did not think that anyone would propose to change his machinery to effect this. He did not imagine that the authors of the paper intended to say, "That is the best form, and we think alternator builders now should build like that." What they said was, "If you build like this, so-and-so will happen." The mechanical difficulties in the construction of the machine and the question of vibration might turn out of more importance than the actual form of the wave. Without explaining his reasons, he thought the authors would agree with him that the eddy-current wave ought to be of exactly the same shape as the P.D. wave, and where that was not the case he thought errors of observation or calculation ought to be looked for. Also they had become accustomed to use the term "effective current," and he wished to enter a protest against dropping it in favour of "root mean square." Lastly, he wished to congratulate the authors on the experimental skill with which they had carried out their difficult investigation.

Mr. Tremlett Carter considered that, in spite of what had been said, the subject discussed was a very practical one, and he could have wished it to have been possible to have had some American engineers take part in it. In America alternator builders were advertising alternators with different wave-forms for different purposes. Curiously enough, they offered a flat-topped wave for transformer work which the authors had proved to be the worst form, and advised a true sine wave for long-distance work, their claim being that the absence of harmonics prevented line losses. The form of wave must be determined by what the transformer had to do, and when it was known what the iron losses were it was possible to select the form wanted. After referring to what had been brought out at the Physical Society as to the effect of the arc on the form of an alternator wave, Mr. Carter complimented the

* Unless the ratio of the maximum of the fundamental to the maximum of the harmonic is greater than the ratio of their wave-lengths, the curve will dip below the zero line at the ends of the half period, in cases such as shown in x, Fig. 21.

authors on the ingenuity with which they had devised the apparatus with which they had obtained their results.

The **Chairman** (Prof. Ayrton) was sorry to see Dr. Fleming had left. He (Prof. Ayrton) was not fond of asking people to take a retrograde step, but he must ask them to go back a year and consider what was the published knowledge on the subject treated of in May last. What was not published knowledge was a different matter, but as far as the authors could know, Dr. Fleming's views then were those quoted in the paper — namely, that the iron core loss was greatest in alternators with a sine curve. It was therefore a fair conclusion of the authors to assume that it was supposed that if the sine wave was the worst a very flat-topped wave would be better. Alternators with the same R.M.S. might have a very different maximum, and going in this direction it was possible to have a flat-topped wave and a very safe machine, and it might be expected from Dr. Fleming's published conclusion that such a wave would be more efficient than a sine wave. The authors, however, found it was little good going in that direction, as a flat-topped wave was the worst form of wave to use. It was not a fact that the sine wave was the worst form. The authors had shown that if you go up (a peaked wave and high maximum) you get danger and efficiency, and if you go down (flat wave and low maximum) you get safety and less efficiency. So far as efficiency is concerned, the sine wave is neither very good, nor very bad. Though that part of the paper had not been read, the researches of Dr. Roessler had not been slurred over, and the authors of the paper had communicated to him (Prof. Ayrton), and, doubtless, to their associates, the conclusions they had come to from their experiments before they had heard of Dr. Roessler's investigations. If it was asked why they had not published their own results several months ago, he was afraid he must confess that it was his (the speaker's) fault. He had persuaded the authors not to publish their results in a weekly journal, but in a paper before the Institution. They all knew the course affairs had taken during the past session. The first meeting could not be held. There had been long debates on house wiring and other matters, and it had only now become possible to bring the paper before the Institution. With reference to their very ingenious instrument, the "injector," in a laboratory where many people were working together, an idea might be transferred from the older to the younger man. But in this case it was not so. The idea was absolutely their own, and he quite agreed that the authors' instrument was at the same time a valuable and an economical one. The great advantage of the instrument was that, instead of wobbling about with harmonics, as some people had done, the authors could produce just the curve they wanted, and, moreover, do it in the same direct way that anyone would draw a curve in practice. If anyone wanted to draw an arbitrary curve, say the profile of a face, he would get the forehead right by itself and then the nose right and then the chin right, and not try to produce it all at once by wobbling about a set of harmonics, and in getting the nose and chin right spoil the forehead. He (Prof. Ayrton) thought the authors were much to be congratulated on their paper, and he did not think that after the way in which Mr. Taylor had read it, his audience would suspect that he had been confined to his bed from illness and had only been able to leave his room two days before.

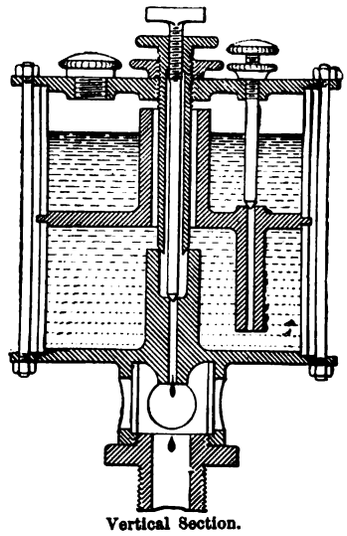
Mr. J. M. Barr replied for the joint authors. The main criticism that had been directed against their paper had been entirely disposed of by what had been said by Prof. Ayrton, and he himself, therefore, would say nothing at all upon that point. With regard, however, to the question of building up a curve with harmonics, the authors thought they had said very plainly that the advantage they claimed for their method over that of harmonics was that if they wanted, say, to take a piece out of curve, they simply took it out at once without in any way upsetting the form of the rest of the curve. He would like, however, to say that no emphasis should be laid upon the fact that they had desired to go outside those wave-forms which were given by alternators in practice. What the authors felt was that the experimenter, working with the machines in practical use, had been beset by the difficulty that using machines giving the same R.M.S. value he did not get very great differences in true area or wave-form. Consequently there was a danger that the differences which he found might be due to, or at any rate not easily distinguished from, merely experimental errors. In order to establish the complete validity of a law, it was necessary to show that it applied to forms that were more extreme than those met with in practice. What the authors had wanted to do, therefore, was to supplement what had been already done with forms of waves met with in practice by seeing how far what seemed to be the conclusions from that work held good when the peculiarities of those waves were exaggerated, and so to render it certain that a given effect was the necessary consequence of any particular form. If, then, they found that they got better and better results as their waves got more and more peaked and worse and worse results the more the wave was flattened, they had shown that the conclusion of the efficiency of a peaked wave was a real one and not merely apparent. That form was therefore desirable so far as the use of it did not lead to other disadvantages. Dr. Fleming had said that it was not true that every alternator had a wave-form of its own, because the wave-form changed with the load. But he had not said that the change was more or less in the direction of a sine wave, and that with a sine-wave machine there was very little change in wave-form as a result of varying the load. As a matter of fact, the authors had found that the wave-form of most existing machines was a very rigid affair, and that a radical method had to be adopted if it was desired to cut out a portion of the wave.

Mr. Taylor added that Dr. Fleming had argued that the wave-form was a very small matter in central-station practice. That might be so; still, he thought it must be an advantage to know exactly all the conditions involved, since unless you knew all the conditions you could not design a central station to the best advantage. He (Mr. Taylor) was not in agreement with Mr. Rhodes in thinking that the eddy-current loss depended on the maximum induction, but upon the mean value of $\left(\frac{dB}{dt}\right)^2$, that is, on the square of the effective P.D.

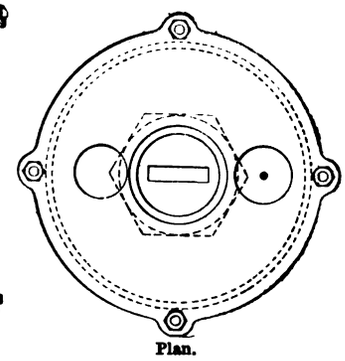
The next and final meeting of the session is on May 28.

NEW SIGHT-FEED LUBRICATOR.

The accompanying illustrations will show the design of a self-filtering sight-feed lubricator which has been brought out by Messrs. Boswell and Carter, of 1, Vere-street, Eccles New-road, Salford. The figures give a vertical section and plan of the lubricator, and it will be seen from them that there are two glass-bodied chambers with a division plate between them. The oil is poured into the upper chamber, from which it flows through an adjustable pilot valve down a tube to the bottom of the lower chamber, the pure and lighter oil rising and passing down centre tubes and past the adjustable and stop valves, and is



Vertical Section.



Plan.

seen dropping through the lantern nipple. The heavier oil or any deposit remains on the bottom of the lower chamber, while any glutinous matter or air bubbles adhere to the sides of downward tube and bottom. If the flow of oil through the pilot valve is interfered with, the reserve of oil from top of centre tube to under side of division plate is drawn upon, and as this oil is used a line of light is seen in the lower chamber below the division plate. Air is admitted to lower chamber through sleeve of regulator-valve spindle, and lubricator can be emptied by simply inverting it. The stop-valve can be closed without interfering with regulator-valve.

THE VALUE OF EXPERT EVIDENCE.

The current that flows in a go-ahead way,
  The current that wriggles about;
The current, *drehstrom*, as the German folk say—
  Oh! which is least open to doubt?

  Go, ask it of Crompton; of Mordey enquire;
    And post it to Nikola T.;
  But their varied opinions will make you perspire
    If you seek for the best of the three.

The engine that drives by the aid of a zone;
  The engine that drives 'em direct;
The engine whose flywheel's not wholly its own—
  Which one have we most to respect?

  Go, ask it of Hammond; ask Charterhouse-square;
    Let Kennedy utter his mind;
  But the varied opinions will cause you to swear
    If you're wishful a moral to find.

The copper that's covered with lead and with jute;
  The copper with papery megs.;
The copper that's clad in a waterproof suit—
  Which, which is the rottenest eggs?

  Go, ask it of Siemens; go, ask it of Gay;
    Ask Nisbett his view of the case;
  But you might as well go to the top Himalay,
  If you've any more questions like these on the way,
    And ask them of infinite space!

THOSE COMPANIES.

Our interest in electrical progress is too great to permit, without grave consideration, our suggesting even caution to investors. It is, then, with qualms that we direct attention to two companies which have been extensively advertised during the week. We have stated before, and we state again, our emphatic protest against all company promoters who foist their wares upon the public without the technical Press having a chance to discuss the value of the goods proposed to be bought and sold. The electrical promoter who has anything good to get rid of has no fear of adverse criticism from the electrical journals. What we all fear is the bringing into the market goods that will not bear expert examination. Now, let us examine the prospectuses of these two companies—the one to put upon the market electric omnibuses; the other, electric mining lamps. Everyone will admit at once the desirability of such vehicles and lamps. With regard to omnibuses, and, indeed, for almost all horseless vehicles, we think that electrical is the only form of energy that can in the long run bear the test of trial. The stink of oil or gas in the crowded streets of our cities would be an intolerable nuisance. Electricity has everything to recommend it except cost. We are speaking only of self-contained vehicles. For many years we have advocated the use of such vehicles, and hoped to have seen progress developed in this way. Gentlemen to whom the cost would be less than that of horse traction could obtain elegantly-designed and light carriages to be driven by accumulators. With such carriages there would be every advantage for the accumulators. An examination of our volumes will show that years ago we expressed an inclination towards direct-current distribution from central stations, and we still believe that alternate-current distribution has, in many instances where chemical action is required, tended against the development of the electrical industry rather than for it. If it were possible to charge accumulators in the stables of every gentleman who keeps horses and who has the house lighted electrically, we believe the getting rid of legislative disabilities would lead to a large number of electrically-driven carriages being used. The advocates of alternate-current distribution have been able to think of one thing, and one thing only—the return at the moment. Let there be no mistake in this matter. We are no thick-and-thin advocates for direct current—we know that each case must be judged upon its merits; but we also know that each case has not hitherto been so judged. The users of accumulators for traction purposes commenced with the worst extreme, and demanded perfection under the most adverse circumstances, coming to the conclusion that accumulators were not worth anything for traction. That was not fair to accumulator makers. In fact, they have never had a fair chance, and we are exceedingly doubtful if the expectation of the promoters will at once be realised with omnibuses; but they seem to think otherwise, and recent information indicates a better state of things at Paris than has been accomplished

Digitized by Google

in England. In our opinion, the earliest development in horseless traction will be—as it should be—with the lighter vehicles, which are not likely to work the accumulators to their fullest capacity; and experience will gradually show how to provide for the heavier vehicles and greater demands.

So far, then, as concerns traction, the present position may be summed up in a few words—horse traction is perhaps indirectly more expensive than any other form of traction. We note with some gratification that a recent leader in this paper, pointing out the probable saving to the rates by changing horse for other traction, has been extensively used by the promoters of various companies. Of all forms of traction, electrical seems the most suitable if it can be carried out at a cost approximating to that which it will have to replace. The other purely electrical company relates to a miner's lamp. This, again, is an application which has been before the public for some years. Many ingenious minds have attacked the problem, but as yet no one seems to have conquered the difficulties. So far as we can gather from the prospectus of the company just announced, there is no indication that the lamp is better or worse than several others. We have the usual expert or inexpert evidence, but we should like to know what earthly value the paid opinions of professors and doctors are on this matter. These inexperts may or may not have actually worked or seen the face of a mine on some gala day in the mine, but we are pretty positive that they have little or no knowledge of the ordinary working conditions. They may retort, "Nor have you." Here we differ; we know both the gala and the ordinary conditions, and know, too, how vastly they differ. We know, too, that other miners' lamps have worked admirably for weeks or months, and that their working has been exceptional—that is, perhaps 5 per cent. of the lamps supplied have worked and 95 per cent. failed. There is nothing in the prospectus of a definite character; but, perhaps, this is because the capital is guaranteed. What we cannot understand is, this being so, why ask the public to subscribe upon such indefinite information?

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

HORSELESS STREET BILL.

SIR,—As one of the earliest workers in the horseless carriage movement, and as the only person who has had the practical experience of running a horseless vehicle upwards of 5,000 miles through the traffic of London streets, I should be glad of this opportunity of expressing, on behalf of all those interested in this immense industry which is now looming on us, our grateful acknowledgment to the Right Hon. H. Chaplin, the Government, and Lord Harris for the great attention and care, having due regard to all the interests involved, that has been taken by them in removing the obstacles that have hitherto stood in the way of horseless vehicle traffic. I do not think that this momentous epoch in this great question should be allowed to pass without also some acknowledgment of the services rendered in connection with this matter by one who has represented the London Chamber of Commerce, and has also been specially able to speak on behalf of the electrical section of the horseless carriage interest, which will have most to do with street and town traffic, as opposed to country road work. I refer to Major S. Flood Page.—Yours, etc.,

RADCLIFFE WARD.

CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS, 1896.

ELECTRIC LIGHTING AND POWER TRANSMISSION.

PRELIMINARY EXAMINATION.

Instructions.

No certificates will be given to candidates on the results of this preliminary examination, but their successes will be notified.

Candidates may take the ordinary grade without having passed the preliminary examination, or both examinations may be taken in the same year.

No candidate who has already passed in the preliminary or in either grade of this subject can present himself for the preliminary examination.

The number of the question must be placed before the answer in the worked paper.

Not more than 10 questions to be answered.

Three hours allowed for this examination:

1. Why are "killed spirits" or "spirits of salt" to be avoided in soldering electric conductors?

2. What are the good and bad points of the following materials if used as insulating materials for switches and cut-outs: wood, porcelain, slate, marble, and red vulcanised fibre?

3. Would you fasten the capping of cases with screws or nails? Give reasons. And what difference would it make if brass screws or copper nails were used instead of iron ones?

4. Suppose you have two leads going up the wall through the ceiling; and a lamp is placed near the ceiling, with the switch on the casing at a convenient height; can a two-groove casing be used for the main leads and switch connections? Give reasons.

5. Show how to join up two electric bells by a single line and an earth return, so that a person at either end can ring up at the other end without ringing his own bell.

6. Define the following terms: resistance, alloy, amalgam, polarisation, E.M.F., one ampere, one ohm, one megohm, one volt, one kilowatt.

7. How many volts are needed to send a current of 20 amperes through a conductor having 10 ohms resistance? What difference would it make in your answer if the circuit included a motor having a back E.M.F. of 450 volts?

8. Why is energy expended in bending or coiling a spring?

9. What is the operation of vulcanising? Why is vulcanised rubber so much used as an insulating material? Why is a layer of pure rubber sometimes interposed between a copper wire and the vulcanised rubber that surrounds it?

10. Under what circumstances would you select as an electromagnet (*a*) one wound with many turns of very fine wire; (*b*) one wound with few turns of thick wire; (*c*) one having its core made up of a number of stampings of sheet iron?

11. Name the chief kinds of batteries used for electric bells and for telegraphy, and the materials used in them.

12. Contrast the advantages of wood casing and of interior conduits for house wiring.

13. Why do sparks occur in ordinary electric trembling bells? How can they be prevented or reduced?

14. How many (electric) horse-power are needed to drive a dynamo supplying 120 16-candle lamps, if the lamps take half an ampere each, and are supplied at 120 volts?

15. What is the use of the shunt coil in an arc lamp? Why is it difficult with some types of arc lamp to work them, two in series, from mains at 100 volts?

16. Show by a sketch or sketches how to make and insulate a T-joint between a $^{7}/_{16}$ conductor and a $^{7}/_{22}$ branch conductor.

Digitized by Google

17. You are directed to run wires for an arc lamp. What thickness of wire would you use, and why? If the wire was for 10 arc lamps in series, what difference would you make in the thickness of the wire, and in its insulation?

18. You are given 16 cells, each having an internal resistance of one ohm. How would you connect them up so as to get as large a current as possible through a wire of four ohms resistance? If each cell had an E.M.F. of one volt, what current would you get through the wire?

WHAT, WHEN, AND WHERE.

Institution of Electrical Engineers.

May 22, 8 p m.—At the Institution of Civil Engineers, Great George-street, Westminster. Students' meeting. Paper on "The X-Ray Photography," by H. L. Tyson-Wolff (student).

May 28, 8 p.m.—At the Institution of Civil Engineers. Ordinary meeting. Paper on "The Utilisation of Water Power, especially with a Small Fall, with some Examples of Plants for the Generation of Electrical Energy," by Alph Steiger.

Institution of Junior Engineers.

May 30, 10.30 a m.—Visit to the Fowler-Waring Cables Works, North Woolwich.

Royal Institution of Great Britain.

May 22, 9 p.m.—At Albemarle-street, Piccadilly. "Hysteresis." Prof. J. A. Ewing.

Physical Society.

May 22.—At Burlington House, "Dielectrics," by R. Appleyard. "The Field of an Elliptical Current," by J. Viriamu Jones. "An Instrument to Measure Frequency," by A. Campbell.

Liverpool Engineering Society.

May 30.—Visit to the Chorley Reservoir.

PHYSICAL EXPERIMENT IN RELATION TO ENGINEERING.*

BY DR. ALEXANDER BLACKIE WILLIAM KENNEDY, F.R.S., M.I.C.E.

(Continued from page 517.)

So far as concerns the training of the faculties of observation at the stage of which I am speaking, probably chemical experiments would serve as well as physical. In certain respects possibly they might even be better, but with this we need not now concern ourselves. An important point is, perhaps, that in their earlier stages the students should not be allowed in any way to get the notion that his experiments are more than mere rough exercises. Any standard of accuracy which he can possibly attain is comparatively a very low one, and by the nature of the case the experiments he can do must be simplified down enormously before they can be put into his hands, so that at best he is only making a rough determination of one element in an artificially simplified operation, the full conditions of which he is not even in any position to understand. The actual figures which are obtained by him can under no circumstances be regarded as having any intrinsic value; and one of the difficulties of the case is, no doubt, to persuade the student to exercise his highest degree of care in obtaining results which at the same time he is told, or knows, are of no use whatever. The engineering student, I am sorry to say, is generally a terrible utilitarian. The unhappy professor has to enter into all kinds of subterfuges to get him to take an interest in, or do any careful work at, matters which the omniscience of youth has once pronounced to be "useless." Later on, of course, he is wiser and a trifle less narrow-minded; but I suppose the stage of first-yearness is one through which all of us have to pass in one fashion or another, to the grief of our pastors and masters, and to our own later regret.

More interesting to most of us, perhaps, than this purely academic matter is the consideration of physical experiment under the last two headings which I have mentioned.

First among these comes experiment which really belongs to pure physics, but in which we engineers may claim to be as much, or even more, concerned than the physicists, although both the difficulty and the honour of the experiment must fall to them. I suggest that we are even more concerned than the workers in pure science for two reasons, of which the first is that the whole of our interest is practically concentrated on what constitutes only a small part of the boundless region open to the physicist. He can spread his affections over glass and sealing-wax, and let them roam from ice to iron. We have only one love, or at any rate never stray very far from a limited number of matters which concern what I have heard contemptuously called "technical materials." He interests himself legitimately and equally in argon and carbon, in steam and in ethyl-alcohol; he loves to extend his thermal conditions so as to get liquid air or gaseous carbon. We, on the other hand, are compelled to deal with a very small number of materials, and with these materials only in states in which we can readily obtain them. In fact, as everyone knows, nineteen-twentieths of our liquid and gas problems affect only liquid and gaseous (or vaporous) water, and only the remaining small percentage is left to be distributed between coal-gas and producer-gas, liquid carbonic acid and anhydrous ammonia, and so forth. So far as the more or less "permanent" gases are considered, our interest is throughout perhaps rather chemical than physical.

Then, again, we may claim to have a first interest in certain physical results, because of the extraordinary frequency with which we have somehow or other actually to make use of them—I mean a real live use, and not merely a use in an examination question, or in a text-book, or a lecture. Not only would our whole work become mere guess-work without the knowledge of these results, but, having this knowledge, we are compelled by the very nature of our work to make such continual use of it that probably we are much more familiar both with the figures concerned and with the phenomena which they represent, than even the men to whose magnificent accuracy and unlimited diligence we owe their original investigation and determination. I mean, of course, such results as refer to the thermal relations of water and steam, to the calorimetry of fuels generally, to many hydrodynamic problems, to most problems in elasticity and what is clumsily called the strength of materials, to frictional questions, to innumerable problems relating to electrical matters, and certainly to an enormous number of matters bearing on mechanics, which, of course, is to be considered as a branch of physics.

I feel so strongly this sense of our paramount interest in certain physical problems that I have not hesitated sometimes to resent the way in which physical writers and speakers are occasionally inclined to instruct us how to express our ideas—for example, as to mass and weight, and sundry vital matters of that kind. I really think that people who have to deal with these matters as much, as often, and as thoroughly as we have, and who are on the whole reasonably competent beings, may be assumed to know how best to manage our own affairs in these respects. Mechanics are to us the breath of our nostrils, and not a mere vehicle for examination papers, and it should be remembered that the requirements of the latter case may be very different from those of what I may venture to call "real life." I feel some satisfaction in remembering that the only fatal case of a misused "g" that I can call to mind was on the part of a physicist, whom we all admire none the less for the way in which he scolds us, but who in the very act of showing us the way we ought to use that symbol proved conclusively that all submarine cables would break by their own tension while lying on the sea-bottom! It would perhaps be hardly proper, or even safe, that I should here say anything, as I am much tempted to do, as to the vexed question of units, which from time to time seems to agitate many minds. Let me only suggest that, on the whole, it does not seem to me that the people who would be most affected by the change are at present those who are most anxious for it. In fact, admitting certainly a few notable and very distinguished exceptions, it really seems as if engineers in general were content to go on in their own way, unconscious of the terrible pitfalls and difficulties by which it is understood that they are surrounded on all hands. I quite admit, of course, that it by no means follows that the pitfalls do not exist, although I confess to being somewhat sceptical about their reality.

But having spoken so strongly of engineers as being the users of certain physical results, I must look at the other side of the matter. We engineers may have, as I urge, more interest in these matters than anyone else, but it is certainly true that we have not ourselves to thank for the determination of the results which we require, and which we make so much use of. For practically the whole of these results—results without which, as I have said, our profession would hardly exist, would at best be a mere trade instead of (as we are proud to consider it) a scientific profession—we are indebted to workers in physical science pure and simple, men without the least taint or suspicion of technical or utilitarian intent.* It would therefore ill become us engineers if we were to say

* The "James Forrest" lecture delivered before the Institution of Civil Engineers, Session 1895-1896.

* I think probably the only notable exception to be made in this matter is in regard to scientific experiments relating to strength and elasticity, some of which have been made by engineers and with a more or less definitely technical intention. But probably such men as Bauschinger, Martens, and Tetmajer are to be considered essentially as in the position of physical workers.

Digitized by Google

or do anything which should, even in the most indirect fashion, tend to belittle the work of pure physicists, on which every day shows us more how much we are dependent. Our gratitude is so real and so deeply seated that we need not, and do not, even resent the expression of regret which has sometimes been heard from a discoverer—that what he has done should be of any use whatever!

A physical experiment such as is necessary for the determination of any one of the physical constants which we have in continual use differs very essentially from such physical experiments as we engineers have to carry out in the course of our own work. It is at once much simpler and much more difficult. It is simpler because its object is the solution of one certain problem, which has been by much care and pains isolated from all its surroundings, from all related and, so to speak, adjacent problems. The first work of the physicist, dealing with his problem, is, in fact, to find out a way of so isolating his question that its solution may give him exactly the one quantity he wishes to know and no other. Of problems of this kind I confess I speak as an outsider, but as an outsider it has been to me often a matter of the greatest interest and even wonderment to see what enormous pains a physicist takes, and must necessarily take, to make sure that he is measuring exactly the thing he wishes to measure—that thing, that whole thing, and nothing but that thing; to see also what innumerable precautions he has to take to ensure the absence of minute errors, or to find out where any such errors might occur, and whether they have occurred, and to evaluate them if they are unavoidable. I have found, too, that in such cases suggestions derived from my own experience in engineering experiment have been often received with a coldness which I am afraid was no more than they may have deserved! For, as I shall endeavour to show, the conditions under which experiments of this kind have to be made are absolutely different, both as to aim and method, from those of the experiments—more technical if not less physical—which we have to carry out for ourselves in our own work.

In a physical experiment of the second category, such as those of which I have been speaking, the primary points may be said to be, first, that the object of the experiment should be single, definite, isolated, separable, and separated from all surroundings; secondly, that it should be general in its nature, and should not relate merely to one special case; next, that as a problem it should be capable of exact determination; and, lastly, that the final result should be as nearly absolutely accurate as it is possible for any physical determination to be. Take as examples such matters as the determination of the density of steam, of the variation of the specific heat of water with change of temperature, of the calorific value of pure carbon, or of the mechanical equivalent of heat. Such problems properly stated admit each of one exact solution, one answer which is absolutely right, even in the mathematical sense of that phrase. It is the highest object of the physicist, in dealing with such a problem, to obtain the right solution. He spares no pains to obtain it; he determines each minute correction with the patience and care of a man who knows that the value of his whole work may be vitiated by a single overlooked source of error, even of the smallest magnitude. We engineers are possibly in some danger of forgetting occasionally, in view of the familiarity and matter-of-courseness of certain figures with which we have frequently to deal, that just these everyday and familiar numbers, on account of their very importance, were those which required and obtained for their determination the most careful, exhaustive, and accurate experimentation in the hands of the most experienced physicists.

After speaking in this fashion of the nature of experiments in pure physics, it may sound at first absurd, but it is nevertheless true, to say that physical experiments in the third category—the technical experiments which we engineers have so often actually to carry out—do not fall under a single one of the conditions which I have just given as characteristic of experiments in pure physics. We cannot, even under the most favourable circumstances, put before ourselves exact and isolated problems; we have much more often to deal with special than with general cases; we cannot choose problems which are capable of finally exact solution; and, therefore, lastly, we should treat the matter entirely wrongly if we attempted to obtain more than a certain limited degree of accuracy in our solution—an accuracy very limited indeed when compared with the all but mathematical accuracy with which problems in pure physics can be solved.

The conditions under which engineers have to carry out physical experiments, of course, vary very greatly. In certain simple cases they are essentially physical investigations, be it in connection with friction, with elasticity, or what not, which at first sight do not greatly differ from the experiments which I have just discussed. There is probably, however, more difference than appears at first sight, although the spirit in which both sets of experiments have to be made is the same. Take as an example the determination of the elastic modulus (or the specific extension) of a piece of steel. Probably, with very perfect instruments and with extreme care in manipulation, a value of the modulus could be obtained which should be accurate, say, within 1 in 2,000 for that particular piece of steel. But a figure so obtained would not be accurate even for other pieces of steel made at the same time, and out of the same ingot as the one experimented on; while, of course, there is no one absolute value for the modulus of elasticity of the widely-differing material of which all sorts go by the name of steel. Under such conditions—and I have chosen a particularly favourable example—it would be mere affectation, and, in addition, would be actually misleading, to claim anything like physical accuracy for our results. Indeed, I must go further and say that the truly scientific way of treating an experiment in engineering physics is to recognise from the outset its limitations as to accuracy, and to be careful not to state a final result in a form which should lead to the supposition of any greater degree of accuracy than that which the conditions of the work can actually allow.

(To be continued.)

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

BY DR. ARMSTRONG, F.R.S.

(Continued from page 520.)

In point of fact, it is necessary that the lessons taught by work such as that done by Stas should be seriously taken into consideration, and that the extraordinary experimental difficulties which such problems present should be more generally recognised. The almost child-like simplicity of faith and belief in the chemist's ability to purify which distinguish our physical colleagues is most remarkable. If we even venture to point out that the material which has been measured with such infinite pains may have scarcely merited so much attention, and thereby hint that the results therefore, perhaps, are but of slight absolute value, we are at once told, "Oh, if you will give us pure stuff we will examine it"; and they might add—but do not—"and secure the credit which will ultimately attach to the work," inasmuch as the mass of figures which they put forward impress the public, whilst the modest statement made by the chemist of the precautions which he has taken in purifying the material—work which may well require the expenditure of infinitely more knowledge and experience, thought, time, and labour than the physical measurements—cannot be appreciated by those who have not themselves taken part in such work. During the past 20 years, Fellows of our society have contributed in a remarkable manner to our knowledge of physical constants, and their work will have an abiding value, as they have taken very special precautions in selecting and purifying the substances examined; but hitherto there has been absolutely no reciprocity, physicists having remained content with a knowledge of the very first principles of chemistry. In the future there must be more effective co-operation between us. In making these remarks I do not wish to blame physicists entirely. I hold that we are ourselves largely responsible for such a condition of affairs, and that it is in no slight measure due to the unscientific manner in which our subject is taught, and especially to the manner in which it is overlain with details which obscure the logical interconnection of its parts.

To return to sulphur, an abstract account has recently been published in the *Proceedings* of the Royal Society (1894, 56, 32) of observations by Threlfall, Brearley, and Allen, on the electrical properties of *pure (sic)* sulphur—*i.e.*, sulphur from the Chance recovery process purified by distillation and exhaustion *in vacuo*. Such a process cannot be accepted as by any means an exhaustive one, and it appears almost to be a case of "love's labour lost" to apply to such material the infinite care which the authors appear to have taken in making the electrical measurements. Yet they arrive at the important conclusion that so long as a single modification be dealt with, such sulphur does not conduct while solid. A mixture of two modifications, however, does; but in view of the possibility of changes taking place during the production of the mixture—of conducting impurities being introduced or generated, it is difficult to regard this latter conclusion as established, the more so as the authors in question have found that as the temperature was raised, the conductivity of the sulphur increased slightly up to the melting point, when there was an enormous increase.

Passing to selenium, there can be little doubt that the properties attributed to this element, and especially its extraordinary behaviour on exposure to light, have been deduced from observations with very impure materials. Shelford Bidwell's recent account of his investigation of this element is full of interesting observations showing, as he says, that the conductivity of crystalline selenium appears to depend principally on the impurities which it

* Presidential address delivered before the Chemical Society.

Digitized by Google

contains in the form of metallic selenides (*Phil. Mag.*, 1895, [5], 40, 233).

The conductivity of what is so wrongly called carbon, in the form used for electric light purposes, is well known to be also electrolytic in character, and is, therefore, most probably conditioned by the presence of salts, and not a specific property of the modification of the element present in such materials.

In the case of the metals also, on the other hand, many observations of great interest have been made, which are highly suggestive, and should serve to incite further enquiry. The electrical conductivity and, at the same time, the mechanical properties of all the highly conducting metals which fall into positions in the periodic system not far removed from that of copper are affected in a most remarkable manner by the presence of minute amounts of impurity, especially by certain non-metallic and metalloidal impurities. Owing to the very large use which is made of it in telegraphy no metal has had more attention paid to it than copper, its manufacture having been greatly improved by the introduction of electrolytic methods in place of the old dry methods. Fitzpatrick, in a report on the specific resistance of this metal, published in the "British Association Report" for 1890, gives a value which is better than that found nearly 30 years before by Matthiessen for "pure" copper in the proportion of 100 : 102·6; but my colleague, Prof. Ayrton, tells me that copper of still higher quality—viz., above 103—is now made on a large scale. It is noteworthy that Swan and Rhodin, in a paper communicated to the Royal Society in 1894 (56, 64), give a value which is not quite so low as that found by Fitzpatrick—viz., 1,563—Fitzpatrick's lowest value being 1,557. They speak of their copper as "pure," stating that it is probable that both of the specimens examined by them were "perfectly pure," and that, in fact, the limit of electrolytic purification had been reached; but this cannot have been the case. Moreover, they, as well as Fitzpatrick and all other observers, obtained different values before and after annealing, the specific resistance of the soft wire being 1,563, whilst before annealing it was 1,603—a circumstance which in itself, I venture to think, affords strong presumptive evidence against the conclusion that we are yet come into possession of practically pure copper, and for the following reasons.

E. van Aubel has observed in the case of bismuth (*Phil. Mag.*, 1889, 28, 332), that although annealing has a considerable effect when the metal is very impure, the effect becomes less and less marked as the impurities are removed, until finally the electrical resistance is scarcely altered by annealing; also, there is a considerably greater difference apparent between the values given for hard and soft copper by Matthiessen than has been found by later workers, who, presumably, have dealt with a less impure metal. Therefore, it appears not improbable that a pure material would suffer no change on annealing—that it would not require annealing, in fact.

Taking Spring's important investigation into the influence of extreme pressure into account, it appears likely that the change during wire drawing—hardening, to undo which resort is had to annealing—is in itself due to the occurrence of chemical change—that is, change in molecular composition; Barus, in particular, has advocated this view (compare *Nature*, 1890, 41, 369), and it has recently received confirmation from observations made by Unwin on the effect of repeated straining and annealing on the yield points of iron and steel (*Proceedings*, Royal Society, 1894, 57, 178). But if change in molecular state in a metal be subject to the same laws as are interactions in other cases, a pure material should not undergo change under the influence either of pressure or of heat, and therefore from this point of view also the fact that all copper hitherto examined is softened by annealing may be regarded as evidence that it has contained impurity.

The nature of the "impurity," the character of the changes which take place in such cases, form subjects of enquiry, not only interesting in themselves, but also of the highest technical importance. With regard to the former, attention may be called to a statement made by Hartley to the British Association Electrolysis Committee in 1887, pointing out that the preparation of pure copper is extremely difficult; and that such as he had had made for spectroscopic purposes, which was considered *pure*, had been found to contain as sole impurity about one hundredth thousandth part of silver, while other samples contained tellurium and bismuth. The photographed spectra were the means of detecting these foreign constituents. I quote this by way of reminder that ordinary, or even extraordinary, chemical tests are of no use in such cases. It must also not be forgotten that gases may become "occluded" during annealing, and, bearing in mind the extreme sensitiveness of copper—especially to oxygen—it would appear necessary in future enquiries to effect the annealing in a "vacuum" from which moisture, oxygen, etc., have been as far as possible removed.

As regards the character of the changes brought about in metals by admixture, we are, of course, but on the very fringe of the enquiry. It is certainly cause for congratulation that men like Roberts-Austen, Dewar (and Fleming), Heycock, and Neville, and Alder Wright—all our own Fellows—have done so much during recent years to extend our knowledge of the behaviour of metals; and we may confidently expect that, now interest is so generally reawakened in metals and alloys, we shall ere long be able to arrive at trustworthy conclusions.

Recent observations on the depression of the freezing points of metals seem to show that, in most cases, the liquid metal consists of monatomic molecules—in itself a very noteworthy conclusion, when it is remembered that the very opposite is true of liquefied non-metals. Whether on solidification, and as cooling takes place, these fundamental molecules form complex groups, is a question which is now being warmly debated, but is a very difficult one to decide: the view advocated by Matthiessen—I am inclined to think with true prescience—that many metals are capable of existing in allotropic modifications—that is to say, in modern language, that they may exist of different degrees of molecular complexity, is at the present time but little approved of, there being a tendency to substitute for it more purely mechanical conceptions. Only in the case of iron is it fairly generally admitted that the facts are such as to make the acceptance of Matthiessen's view almost compulsory. Osmond—whose work is of extraordinary interest and of the highest value—indeed has argued that this metal may exist in no fewer than three allotropic forms.

In the case of a pure metal, consisting in the fused state of monatomic molecules, it is conceivable that when solidification takes place interatomic forces come into action in such a manner and so uniformly that the mass, as it were, forms one huge complex molecule. This could scarcely happen if impurities were present; but in that case similarly constituted smaller complexes—individual crystals—might form. The observations of Behrens on the microscopic structure of alloys of silver and copper are perhaps of significance from this point of view, showing as they do that, whilst the crystals are scarcely distinguishable in "pure" copper, in copper containing only a minute proportion of silver they become distinctly visible, and are seen to be separated by a film of white alloy.

It is difficult to resist the conclusion that the properties even of congeries of such crystal molecules as are above referred to are not somewhat different from those of the simple fundamental molecules *en masse*. Silver, copper, and gold, it is well known, are possessed of high electrical conductivity, especially silver and copper, which are all but alike in this respect; and yet, as Matthiessen has shown, when any two of them are mixed, the conductivity of the mixture is lower to an extraordinary extent than that of either alone. That such an effect should be produced is very remarkable, and it is difficult to understand how it can be brought about by the mere admixture of molecules which apparently are equally effective conductors; this behaviour would seem, indeed, to be an indication either that the molecular state of the metal is changed, and that, in fact, it is converted into a modification possessed of lower conductivity; or that a compound of the two metals of lower conductivity is formed and becomes interposed between the highly conducting crystals.

The remarkable behaviour of silver towards oxygen also serves to suggest that the silver atoms combine on solidification. The fact that this metal is a solvent specifically of oxygen, and not of gases generally, is in a measure evidence that combination takes place between it and the gas; and on this assumption the well-known spitting may be explained as due to the occurrence of an interaction conditioned by the superior affinity of silver to silver outweighing that of silver to oxygen in the manner indicated by such an equation as $xAgO_2 = Agx + xO_2$. But this explanation does not necessitate the conclusion that the silver atoms combine otherwise than throughout the whole mass.

The evidence that one metal may combine with another is now so entirely beyond question that it is no longer open to doubt that like metallic atoms may combine. The eminently plastic character of some highly purified metals—*e.g.*, copper, gold, silver, iron, platinum—would, I imagine, lead us to prefer the view that they consist of relatively simple, if not of monatomic molecules. Whilst, on the other hand, the extraordinary brittleness produced on adding small proportions of certain elements to some of these metals is perhaps best explained by the assumption that such additions cause the formation of complex molecules having but little tendency to cohere. Such a conclusion is almost necessary in the case of iron, in which, as is well known, extraordinary alterations may be produced by altering the distribution of the impurities, without altering their amount—I allude to the passage of carbon from the combined into the free state during the rapid cooling of steel, and to the change in the opposite direction which takes place during slow cooling. Iron, indeed, is one of the most remarkable among metals, and there is no literature more deserving of the chemist's attention than that relating to the researches of Roberts-Austen, Barus, Hopkinson, Osmond, and others who, during recent years, have contributed in a most important manner to our knowledge of the changes going on in iron and steel.

Osmond assumes that even "pure" iron alters in molecular

Digitized by Google

composition as it cools, basing this conclusion on the observation that the electro-deposited metal exhibited the phenomenon of recalescence—but the conclusion that such iron is, to use Roberts-Austen's expression, "as pure as any iron can be" may fairly be called in question, especially as Osmond speaks of it as containing a little carbon (0·08 per cent., *Iron and Steel Institute*, 1890, i., 38), and it may be doubted whether any such change would take place in pure iron. In presence of carbon, it would seem that when the temperature has fallen sufficiently molecules which are more complex than those existing at the higher temperature are formed, heat being liberated, thus giving rise to recalescence; the extent to which such complexes are formed largely depending on the amount and character of the impurity present. Perhaps it is from these complex molecules that the peculiar magnetic properties of steel are derived. The separation of carbon from iron may well take place at the moment when the complexes are formed, and the change which occurs at its separation may be of the character of that referred to above in connection with the spitting of silver. The carbide which is produced during slow cooling may conceivably be generated by the interaction of the complex molecular form of iron with the carbon. The explanation of the changes here discussed, advanced by Osmond, involving as it does the assumption that at high temperatures iron consists of the hard modification which unless prevented passes into the soft modification on cooling, seems to me to be less natural and likely than the foregoing.

It is to be hoped that ere long methods will be devised of preparing considerable quantities of iron in a state closely approaching to that of purity, so that the individual influence of various foreign substances may be studied. At present we do not seem to be aware whether the presence of carbon especially is essential to hardening, and whether this element alone can condition the state which renders steel capable of becoming permanently magnetic. Sufficient will have been said, I trust, to emphasise the extraordinary importance of attention being paid to the behaviour of highly purified substances. Enough is known to warrant the assumption that in many cases such investigations will show that properties associated with individual substances are wrongly regarded as specific, and that in reality they are determined by an admixture. To give but one more illustration, if conduction in solids other than metals be always electrolytic conduction, conditioned by the presence of composite electrolytes, a condenser such as a Leyden jar may be regarded as a voltaic cell in which the electrolyte is a solid of high resistance, and its action as dependent on polarisation; the difference between such a cell and one containing a fluid electrolyte arising from the fact that in the latter polarisation cannot be maintained except at the electrodes, whilst in the former the polarisation extends throughout the electrolyte. On this assumption it should be impossible to form a condenser from a pure substance. I venture to point this out as showing the great importance of experiments being instituted with very highly purified dielectrics.

The more our attention is directed to the important part which impurities play in determining change, whether it be in metals, non-metals, or compounds, the more necessary is it to enquire into the possible mechanism by which such change is brought about. So long as we are entirely unaware of the nature of chemical affinity and of the manner in which it is exerted, little progress can be made; there can scarcely be a doubt, however, that what has been termed residual affinity is largely operative, as, indeed, Faraday foresaw. The following remarkable passage in his fifth series of researches (§ 523) is almost as clear a statement of this view as could be given at the present day: "The theory which I have ventured to put forth (almost) requires an admission that in a compound body capable of electro-chemical decomposition the elementary particles have a mutual relation to, and influence upon, each other, extending beyond those with which they are immediately combined. Thus, in water, a particle of hydrogen in combination with oxygen is considered as not altogether indifferent to other particles of oxygen, although they are combined with other particles of hydrogen; but to have an affinity of attraction towards them, which, though it does not at all approach in force, under ordinary circumstances, to that by which it is combined with its own particle, can, under the electric influence, exerted in a definite direction, be made even to surpass it. This general relation of particles already in combination to other particles with which they are not combined is sufficiently distinct in numerous results of a purely chemical character . . . and it probably has a direct relation to, and connection with, attraction of aggregation both in solids and fluids. It is a remarkable circumstance that in gases and vapours, where the attraction of aggregation ceases, there likewise the decomposing powers of electricity apparently cease, and there also the chemical action of quantity is no longer evident. It seems not unlikely that the inability to suffer decomposition in these cases may be dependent upon the absence of that mutual attractive relation of the particles which is the cause of aggregation."

(To be continued.)

HUDDERSFIELD.

The Corporation of Huddersfield have just issued their electric supply accounts for the year ended December 31, 1895. We give below the revenue account and balance-sheet, together with the statement of electricity generated, sold, etc.:

Dr. Expenditure.				£	s.	d.
Coal, or other fuel, including dues, carriage, unloading, storing, and all expenses of placing the same on the works	£541	18	1			
Oil, waste, water, and engine-room stores	48	4	5			
Wages at generating station	625	16	6			
Repairs and maintenance as follows: buildings, £39. 17s.; engines, boilers, £67. 10s. 5d.; dynamos, exciters, transformers, motors, etc., £14. 11s. 10d.; other machinery, instruments and tools, £83. 8s. 5d.	205	7	8			
				1,421	6	8
Wages, etc., to linesmen, fitters, labourers	61	0	3			
Repairs, maintenance, and renewals of mains of all classes, including materials, and laying the same	31	7	7			
Repairs, maintenance, and renewals of transformers, meters, switches, fuses, and other apparatus on consumers' premises, together with cost of materials and lamps sold, as *per contra*	52	18	2			
				145	6	0
Attending and repairs				60	12	5
Rents payable	44	12	7			
Rates and taxes	284	16	10			
				329	9	5
Salaries—viz., engineer's department	445	0	0			
Accountant and clerical staff	199	19	0			
Stationery, printing, and advertising	59	2	2			
General establishment charges	174	18	9			
				878	19	11
Insurances, etc.				6	6	0
Total expenditure				2,842	0	5
Amount carried to net revenue account				2,474	4	7
Bad debts written off in excess of amount brought from last account, £2. 13s. 7d.; balance carried to next account to provide for bad debts, £32. 6s. 5d.				35	0	0
				£5,351	5	0

Cr. Income.	£	s.	d.
By electric supply—Sale of current per meter at 6d. per B.T.U.	4,713	18	8
Sale of current per meter at 4d. per B.T.U.	12	7	4
Sale of current per meter at 2½d. per B.T.U	5	16	2
Sale under contract	143	0	0
Public lighting	180	0	0
	5,055	2	2
Rental of meters and other apparatus on consumers' premises, £218. 1s. 1d.; sale and repairs of arc or incandescent lamps and repairs of other apparatus, £78. 1s. 9d.	296	2	10
	£5,351	5	0

BALANCE-SHEET.

Liabilities.	£	s.	d
Capital account—amount received	49,500	0	0
Sundry creditors	4,088	3	3
	£53,588	3	3

Assets.	£	s.	d.
Capital account—amount expended for works	49,079	6	2
Stores on hand at Dec. 31, 1895: coal, £2 12s. 6d.; oils, waste, etc., £9. 19s. 6d; general, £94. 5s. 4d.	106	17	4
Sundry debtors for current supplied to Dec. 31, 1895	2,855	18	3
Other debtors	162	17	6
Revenue account, balance at debit thereof	1,373	4	0
Cash in hand (engineer)	10	0	0
	£53,588	3	3

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.			342,692
Quantity sold: Public lamps	6,760		
Quantity sold: By contract	14,669		227,753
Quantity sold: Private consumers by meter	206,324		
Quantity used on works			10,047
Total quantity accounted for			237,800
Quantity not accounted for			104,892
Number of public lamps			4
Total maximum supply demanded (B.T.U.)			308

ON THE USE AND ECONOMIES OF RECTIFIERS FOR ARC LIGHTING.*

BY JOHN HESKETH, MEMBER OF COUNCIL.

The first practical use of electrical energy for lighting purposes was by means of arc lamps, and this method still remains to-day the most economical means of lighting possible in the present state of our knowledge. It is only reasonable, therefore, to expect that the theory and practice of arc lighting, and the knowledge of the arc lamp with its accessories and special plant, should be the most fully developed and perfected of all our electrical knowledge. But such, unfortunately, is not the case. Of all the existing systems of arc lighting, whether public or private, scarcely one exists in which some glaring inefficiency does not appear. The fact that we have all known of this lamentable condition of affairs for many years in a dim, uncertain way has perhaps hardened our hearts, and made us condone a technical sin sanctioned by common consent. Perhaps, too, the fact that, until recently, arc lighting has not been very largely adopted in England has influenced our views; the result from whatever cause has been that, speaking broadly, the thought and care given to machines, systems, and schemes for incandescent lighting has not been extended, except in a half-hearted way to arc lighting. In England arc lighting has been a side show, and incandescent lighting the main purpose of electricity works; and even in America, where in many stations the order is reversed, the inefficiencies still exist, but, it is only fair to admit, in a greatly reduced degree.

It is not with any intention to discuss the whole of this problem that the present paper is undertaken, but only to detail recent experiences in the use of one special form of apparatus and system of generating the necessary energy. The question of distribution and utilisation of such energy in arc lighting is sufficiently wide to form matter for papers for a complete session. In special reference to the subject of this paper, it is interesting to note that the first arc lamps used in French lighthouses were supplied from alternators fitted with commutators, and so were virtually rectified current arc lamps. In the earliest installation of public arc lighting plant in England, of which I think Blackpool was the first example, the practice was to run each lamp from a separate machine, so that in such a station one or more engines running on to a counter-shafting drove the dynamos and exciters, each dynamo feeding its own arc lamp though a separate lead and a common uninsulated and buried return. That such a system of generation was most inefficient is very apparent. The system of distribution and utilisation of light was perhaps equally so, and it was not long before the system, not only of distribution, but of generation, was altered completely. Installation of arcs connected in series and run from special machines, such as Brush or Thomson-Houston, began to appear, and although the machines were admittedly inefficient, and in their ordinary sizes have not been much improved, they still continue to be most generally in use. We are aware that recently the efficiencies obtained in America by the use of 50 to 55 kilowatt Brush dynamos (100 to 110 arc machines) has risen considerably above any known in England, but the conditions of practice there are widely different from those in England. The need for a public supply of incandescent lighting led in one or two instances to the expedient of running incandescent lamps in series with arc lamps from Brush machines, but as the demand for private lighting increased much more rapidly than that for public lighting, separate machines and systems gradually were adopted, and the question of generation for series arc lighting was allowed to lapse for a while. But recently the fact has been recognised that two different types of generating plant being allowed to exist in one building for purposes which could very well be fulfilled by one was most illogical and inefficient, and has resulted in a reopening of the question. This is assisted by the fact that the arc lamp is at last being recognised as the only rational means of public lighting, and its use is therefore being very rapidly extended. On continuous-current supply systems, the problem of arc lighting is not difficult of solution. The ordinary network has its coefficient of service increased by connecting the public lighting to it, but in alternating-current supplies the case is different. The alternating-current arc lamp is not so efficient as a generator of light as the continuous-current arc. The reasoning of Prof. Forbes in his recent Cantor lectures to the contrary is very interesting, but, as it is in direct conflict with the results of all experiments hitherto made, we are bound to confess that in the present state of our knowledge the alternate-current arc is not so efficient for public lighting as the continuous-current. The examples of public lighting by alternate-current arcs which have been recently carried out in various places may be excellent in themselves, but comparatively their efficiency is not equal to that of continuous-current arcs.

This is so far as we at present know. The investigations being carried out by so many authorities on this subject may result in the discovery of a more rational proportion between current strength and size of carbon or other factor which may influence the luminous efficiency, but for the present we will discuss matters as they are. The blue tinge of the alternating arc is an objection which may be got over by colouring during diffusion or alteration in the constitution of the carbons. Among the possible solutions are the following: (*a*) alternate-current arcs, with a separate transformer for each lamp; (*b*) arcs three in series off 100-volt network or separate transformer for three arcs; (*c*) any number of arcs in series off an alternate-current transformer giving varying voltage and constant current and delivering alternate currents into the lamps; (*d*) as in *c*, but with commutator or rectifier in the secondary circuit, so that pulsating currents are delivered into the lamps.

But the inefficiency of the alternating-current arc will veto the adoption of the solutions *a*, *b*, or *c*, unless the efficiency of one generating plant over two is so great as to justify the consequent loss in utilisation. The fact that the two first systems have been practically adopted, and the third suggested, is evidence of the feeling that an advantage is to be gained by having only one type of generating plant. All these reasons speak with even greater force in favour of the solution *c*, for in addition to every economy gained by systems using only one type of generating plant, it possesses the great advantage of giving arc lamps having a photometric curve very approximately equal to that of an ordinary continuous-current arc. Having gone thus far into the reasons for the adoption of a rectifier, it may be well to describe the apparatus and discuss the various points arising from its use.

Description of a Rectifier for Arc Lighting.—The rectifier consists of two points—a constant-current transformer and a synchronous motor on which is fixed the rectifier commutator. A transformer, with switches for regulating the secondary voltage, drives the synchronous motor. The two primary coils are fixed on to the horizontal limb of the iron circuit. The four secondary coils are movable, and on either side of the fixed primaries. Counterpoises are fixed to the suspending rods of the movable coils so that the repulsion between the primary and secondary is just balanced when the normal current is given out by the secondary—any increase tends to make the movable coils widen out and a decrease allows them to close together again. The net result is that the varying current at constant pressure, which is sent into the primary, is transformed into a constant current at varying voltage in the secondary. But this current is still alternating; so it is led to the commutator fixed on the end of the motor shaft. The brushes are adjustable by hand, and are so set that the current is commuted when it is at zero. As has already been stated, this shape of current is quite suitable for arc lamps, and allows them to derive all the advantage of continuous currents, while the uniformity of plant in the generating station is maintained. The most natural divisions into which a consideration of the uses of the rectifier falls are (1) efficiency of rectifier, *per se*, both apparent and real; (2) influence of rectifier on the total efficiency when used in conjunction with private lighting plant; (3) effect of rectified currents on arc lamps and other points in the practical use of rectifiers and miscellaneous notes. In considering this question the comparative figures are necessarily taken from Blackpool station, where Brush machines, rectifiers, and alternating arcs, on both simple parallel three-wire and three-in-series systems, are in use. The figures may vary with each particular case, but the broad principle is unchanged.

Efficiency of Rectifier.—The apparent efficiency of a rectifier is of almost as much importance as its real efficiency, for if the power factor be low, the apparent current being high prevents the generating plant being used at its highest capacity, for it is the current density in the armature which, almost always, is the measure of a safe load on any machine. It is therefore highly important that the power factor of a rectifier should be high. This is, unfortunately, opposed to the attainment of a very high percentage of regulation, for it is equally important that with a varying load from, say 10 per cent. to full load, the current should remain sensibly constant, and this result can only be obtained by a certain loss in efficiency. However, in the more recent types of rectifier, an apparent efficiency of 90 per cent. and a true efficiency of 95 per cent. is obtained with good regulation between one-tenth load and full load. The results with the earlier types were not so satisfactory on account of greater attention being paid to regulation than to efficiency, but seeing that on public lighting circuits the load ought never to fall below 50 per cent. of full load, there is no necessity for good regulation below that point except in the case of a blow over on to the secondary commutator, but even in this case the regulation need only be such as to prevent damage to the windings through overheating or fusion of the brushes.

Influence of Rectifier on the Total Efficiency of a Lighting Plant. — For a modern steam alternator an efficiency $\frac{\text{E.H.P.} \times 100}{\text{I.H.P.}}$ of 85 per cent. is unusually high. And as the efficiency of the rectifier complete is 90 per cent., it follows that the efficiency $\frac{\text{energy in lamps} \times 100}{\text{I.H.P.}}$ is equal

* Abstract of paper read before the Northern Society of Electrical Engineers, May 11, 1896.

to 95 per cent. of 85 per cent. = 80·75. This is looking at it in its barest and least favourable light. If we compare the efficiency of an alternate-current plant and rectifier with a Brush or Thomson-Houston plant, the comparison is still more favourable. The following are results of tests of a Brush 55-lighter set at Blackpool under ordinary working conditions: The engine was a horizontal compound engine by Fowler and Co.; cylinders, 9in. and 14in. by 16in. stroke; speed, 150. The dynamo was a Brush 8 L machine. Tracings of the indicator cards are annexed hereto. For this type of engine they do not show any abnormal characteristics, excepting the want of balance between the high and low pressure cylinders. This, however, would not affect the efficiency to any great extent.

TABLE I.

—	5	53·57	40·518	12·58	23·299	63·817	2300	9 8	30 214	47·346
—	6	55·05	41·637	12·77	23·635	65·272	2300	10·0	30 831	47·235

Mean efficiency 47·37 per cent., as against 80·75 per cent. for rectifier and alternator. I am quite aware that the results are low. Indeed, they have been exceeded at Blackpool, where the same plant when new gave slightly better results. The difference, however, was not more than 5 per cent. The efficiency of some American plants using larger sizes of Brush machines is as high as 75 per cent. But this is exceptional. But the comparison is by no means ended here. As already indicated, 55-lighter (30-kilowatt) arc machines are about the largest generally in use in England, and such a dynamo rope-driven from an ordinary engine takes up a floor space of about 500 square feet. This is leaving a space 2ft. wide round the plant for attendance. Such a plant direct-driven would take up only 220 square feet, or 16 and 7 square feet per kilowatt respectively. A modern 300-kilowatt steam alternator would occupy 500 square feet, or 1·6 per kilowatt. If space for 300 kilowatts of rectifiers be included, this will add 200 square feet to the last figure and make the gross space per kilowatt 2·3 square feet. The importance of this point is most apparent. The fact that a power equal to 10 55-lighters can be generated by one steam alternator and attended to by one man is another. So far the arguments have been confined to those in favour of rectifiers *versus* other types of machines for series arc lighting only. The next point worthy of consideration is that, the load of the rectifier being dealt with by the energy lighting plant, its efficiency should really be $\frac{\text{energy in arcs}}{\text{added energy in engines}}$. For example, suppose a station to have a load of 200 kilowatts and to have 100 kilowatts in rectifiers added. The true measure of the efficiency should be, not $\frac{300\ \text{K.W.}}{\text{I.H.P.}}$, but $\frac{300\ \text{K.W.} - 200\ \text{K.W.}}{\text{I.H.P.}_2 - \text{I.H.P.}_1}$, where I.H.P._1 is the indicated horse-power to drive the ordinary load, and I.H.P._2 to drive the combined loads. Table annexed gives indicator cards taken from 200-kilowatt plant when driving, first, ordinary load; second, ordinary load with rectifier added.

Effect of Rectified Currents on Arc Lamps.—Rectified currents, when sent through circuits having self-induction, produce effects intermediate between those observed with direct and alternating currents. To observe the extent of this effect the following experiment was carried out with the results tabulated. A measured current was sent through a choking coil, and the voltage at the terminals of the coil noted. With a current of 9·52 amperes flowing, the voltage at the terminals of the impedance coil were:

For continuous current from a Brush machine ..... 5·76 volts.
For alternating currents 83 ⌒ per second from an E.C.C. alternator ..... 83·0 volts.
For the above currents rectified ..... 57·5 volts.

It therefore follows that in arc lamps intended for use with rectified currents main cores should be laminated and the bobbins split. It is not necessary that this be done for the shunt coils. The "pull" on the core is rather less and more sluggish than with a continuous current, so that a fresh adjustment requires to be made. The lamps are also perceptibly longer in "striking" than with continuous currents. The illumination from a rectified arc lamp is not perceptibly different from that of a continuous-current arc. For photometric curves of any reliability to be made requires more elaborate apparatus than is generally found in an electric supply works, but I append hereto the results of trials up to date.

Effect of Rectified Current Series Arc Lighting Circuits on Telephones.—There is an undoubted influence on telephone circuits when rectified currents are used in series circuits as generally arranged. The means for the prevention of such interference are peculiar to each case; but, speaking generally, they are such as apply to the prevention of interference of one telephone line upon another—that is, perfect electrical balance on the circuit and perfect insulation.

Maintenance of Rectifier.—The apparently heavy sparking at the brushes of a rectifier is not so damaging to the commutator as might be imagined; with care the commutator will last quite as long as those of other types of arc lighting machines. Care has to be exercised in the set of the brushes, both on the low-tension or motor end and on the high-tension or rectified end. The influence of the method of driving the alternator on the motor is very perceptible—with one machine the motor current is as steadily low as possible, while with a small machine, lightly loaded, on which the ropes jump, the motor current has to be set fairly high if steady running has to be obtained. The danger from the use of a rectifier for currents at such high tension which has been mentioned by one or two people, has not shown itself in practical use with us. The maintenance of the apparatus has been a matter of much greater ease and economy than of any other arc lighting plant in the station. This is not difficult to understand, as only two coils are movable, and these need not move more than 6in. a day. Excellent insulation is obtained, and altogether there is every facility for easy maintenance.

Conclusion.—It is with the hope that a discussion on the various systems of generation for arc lighting may be opened that this paper has been prepared. It is undoubted that there are more inefficiencies in our present arc lighting systems than in any other branch of electrical engineering; and the most lively satisfaction of the writer will be experienced if a closer investigation into all the details of this most important branch is provoked.

THE PHYSICAL SOCIETY.

At the ordinary meeting of May 8, Captain Abney, president, in the chair,

Messrs. Frith and **Rogers** read a paper on **"The True Resistance of the Electric Arc."** It was pointed out by Prof. Ayrton, at the British Association meeting at Ipswich, that if the "true resistance" of an arc was defined as the ratio of a small increase of the P.D. between the carbons to the corresponding change in the current, then it follows that this "true resistance" must be a negative quantity. In order to measure the "true resistance" without appreciably altering the form of the carbons, etc., the authors superpose a small alternating current on the main continuous current. The arc lamp employed was adjusted by hand, and the arc length was measured by projecting an image of the arc by means of a lens. The main (continuous) current and P.D. were measured by a Weston ammeter and voltmeter, while the auxiliary alternating current was measured by means of an air transformer and an electrostatic voltmeter. The authors found that between the limits employed the magnitude of the alternating current did not influence the results obtained for the resistance of the arc. The frequency, so long as it lay between the limits 250-7 complete alternations per second, and the wave-form did not influence the resistance, since the same results were obtained with a Pyke and Harris alternator, a Ferranti alternator, a Gramme alternator, and a Mordey transformer. For each make of carbon examined four combinations were used: + cored, - cored; + cored, - solid; + solid, - cored; + solid, - solid. The general character of the curves obtained was that for the + solid, - solid combination the "true resistance" was always negative, while for + cored, - cored it was always positive, the other curves being between these two extremes, those which had the + carbon solid always being more negative than those which had the + carbon cored. In the case of the curves showing, for solid carbons, the relation between the resistance of the arc and the P.D. between the carbons, the current being constant (10 amperes), a minimum—*i.e.*, a maximum negative—value for the resistance occurred at about 55 volts. With combinations having a cored positive this minimum became more strongly marked, and occurred at a lower voltage. The authors found that for cored carbons the position of this minimum was closely connected with the presence or absence of the dark space in the arc. For points on the curve to the right of the minimum point the dark space was absent, while for points to the left of the minimum the dark space was always present. It was found that the effect of using as the + carbon a Carré carbon, in which the core had been bored out, was to obtain a curve closely resembling that obtained when both carbons were solid. On filling this hollow carbon with plaster of Paris or kaolin the resistance of the arc became positive. The above experiments were made with the + carbon uppermost. Other experiments made with the arc inverted showed that with solid carbons the resistance was not appreciably altered by inverting the arc. With cored carbons, however, the resistance as well as the physical character of the arc was altered, for on inversion the dark space disappeared and the resistance considerably diminished. If, however, the conditions under which the arc was

Digitized by Google

burning were such that the dark space was absent, then inverting the arc did not alter the resistance. Attempts were made to measure the "true resistance" of a direct-current hissing arc, but it was found that even with the alternator at rest there was a large deflection of the electrometer, showing that the current through a hissing arc was oscillatory. In order to elucidate the marked difference between their results for cored carbons and those deduced from Mrs. Ayrton's curves, the authors made a series of measurements at low frequencies. They found that there is a critical frequency above which the resistance has a positive value which is independent of the frequency, and below which it has a negative value, this critical frequency being between 75 and 0. In order to investigate the sign of the resistance at low frequencies, the vibrations of the needles of the ammeter and voltmeter were made use of. By an arrangement of mirrors the needles and scales of both instruments could be observed simultaneously. In this way it could be seen whether the two needles were at any instant vibrating in the same or in opposite directions. If the needles vibrate in the same phase—*i.e.*, if an increase of P.D is accompanied by an increase of current—then the "resistance" must be positive, while if they are vibrating out of phase—*i.e.*, if an increase of P.D. is accompanied by a decrease in current—then the "resistance" is negative. An attempt to run the arc off a continuous current dynamo failed, since even with the alternator at rest the electrometer showed a large deflection, evidently due to the oscillation of the current owing to the commutator of the dynamo having a finite number of segments.

Prof. A. Gray doubted whether it was right to give the name "true resistance" of the arc to the slope of the curve connecting the potential difference (V) and the current (A). The author's method of deducing $d\,V/d\,A$ was only true if the curve was a straight line.

Mrs. Ayrton said that with reference to the question of the existence of a back E.M.F. the evidence tended to show that it did not exist. By using an exploring carbon no constant back E.M.F. could be found.

Prof. Ayrton said that, considering the arc as consisting of a back E.M.F. and a resistance, it was necessary to separate these two. Simply obtaining one value of the P.D. and the current was of no assistance in solving the question, but a series of values had to be taken. By taking the change in P.D and current sufficiently small, the curve over the range considered was practically straight. It was curious to note that as long as observers obtained a positive value for the resistance of the arc no fault was found with the method, but that now a negative value was found the accuracy of this method was questioned. If a back E.M.F. did really exist, then it followed that the arc must have a negative resistance. Mr. Frith had shown why some people had got positive and some negative values for the resistance of the arc, and also that with an alternating current it was possible to get either one or the other.

Mr. T. Carter asked if the fact that the arc had a negative resistance did not imply a back E.M.F. in order that the arc might be stable? If so, was a negative resistance such an absurdity?

Mr. Campbell said he was very pleased to see that the authors had applied a method which he (Mr. Campbell) had suggested for measuring pulsating currents. If a pulsating current such as could be obtained by means of a make and break was passed through a thermopile you would get a back E.M.F., while if an alternating current were employed you would not.

Mr. Frith, in his reply, said that he had defined the "true resistance" as $d\,V/d\,A$. Mrs. Ayrton had shown that an arc would not run unless a certain resistance was placed in series with it, and this resistance must be numerically equal to the negative resistance of the arc itself.

Prof. Ayrton said Mr. Frith's remarks as to the cause of the want of stability of an arc without outside resistance were most suggestive.

The **Chairman** (Captain Abney) said he did not like the expression P.D. He suggested the employment of photography to facilitate the accurate registration of the instrument readings.

The further discussion on the paper was adjourned.

LEGAL INTELLIGENCE.

COLLISION WITH A MANX TRAMCAR.

In the Common Law Division of the Manx High Court at Douglas, on Saturday, before Deemster Drinkwater, the hearing of the action of Wm. Henry Lawson *v.* the Isle of Man Tramways and Electric Power Company, Limited, was continued and concluded before a special jury. Mr Kneen was for the plaintiff, and Mr. Ring and Mr. Brown were for the company. The plaintiff claimed damages in respect of injuries to his horse, carriage, and person from a collision with a tramcar, alleging that such injuries were caused by the negligence of the company's servants. The company denied negligence, and pleaded contributory negligence.

A visitor named **Spencer**, from Stockport, having given evidence absolving the company from negligence,

Mr. Ring contended that the injury to Lawson was suffered by his own reckless driving, and the negligence was solely with himself and not the company.

Mr. Kneen addressed the jury for plaintiff, and the judge reviewed the evidence, summing up strongly in favour of the plaintiff.

The jury found a verdict for the plaintiff for £30, being £25 for damage to horse and carriage, and £5 personal injuries.

COMPANIES' MEETINGS AND REPORTS.

WEST INDIA AND PANAMA TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Wednesday at Winchester House, E.C., Mr. C. W. Earle presiding.

The **Chairman**, in moving a resolution for the adoption of the report and the payment of dividends, remarked with satisfaction on the turn which had been taken in the long-continued decrease in their traffic receipts, there having been an improvement of £1,083 as compared with the receipts for the December half of 1894. It was true that that amount had almost been wiped away by the loss of the French subsidy for Guadeloupe, but this they had foreseen, and was a loss which they had no means of escaping from. Their traffic receipts, in view of the fact that they had about 5,000 miles of cable and that they served 16 colonies, were almost ridiculous, the gross amount being about £2,500 a fortnight. The expenditure was kept down to the lowest possible sum consistent with an effective service. They had put into the system less cable by 30 knots than they did in the corresponding period of the previous year, and this had caused a considerable diminution in the expenses under this heading—£2,831, compared with £5,876. They brought home the "Grappler" to take out a new supply of cable for stock. If they had not done this, they would have had to charter a vessel out, and therefore they had charged this cable with a fair amount of the cost of the two voyages of their vessel. This had saved them about £2,000, but for which they would not have been able to pay the dividend now proposed of 6d. a share on the ordinary shares. Since the close of the half-year the St. Vincent subsidy had been reduced from £600 to £400 owing to the financial condition of the colony. Probably most of those present had seen Mr. Chamberlain's answer in the House of Commons when he was asked about laying a cable between Bermuda and Jamaica. They had been in correspondence with the Colonial Office on this matter, and at the proper time, if anything were settled, they would place it before the shareholders and ask their opinion upon any terms which might be proposed to them. The question of that cable was a very old one. In 1882, when it was advocated, and very strong pressure was then put on the then Government to lay it, Mr. Fawcett, who was then Postmaster-General, expressed the belief that there would be just cause for complaint against her Majesty's Government if it were to subsidise a rival company. Influenced by those words, their Company went on its course, and continued the duplication of its system, which had given permanent security in communicating to the West Indies. It would, therefore, be very unjust to employ the taxpayers' money to run a competitive line to this Company's in view of the statement made by Mr. Fawcett which he had quoted.

The resolution was seconded by **Mr. W. Andrews**, and carried unanimously.

READING ELECTRIC SUPPLY COMPANY, LIMITED.

The second annual general meeting of this Company was held last week, Mr. Henry Collins (chairman) presiding.

The directors' report and accounts for the year ending December 31 showed for the year an income of £1,453. 10s. 7d. and a balance of £22 13s. 4d. This they considered very satisfactory, seeing that the new central station had been only in use for the last two months of the year, and with an increased demand for current they anticipated a corresponding increase of revenue. Since the new station had been opened the number of consumers had increased rapidly. Thus on December 31, 1894, there were 38 consumers and 2,150 lamps wired; on December 31, 1895, 83 consumers and 4,300 lamps; on April 17 last, 106 consumers and 6,094 lamps; at present, 115 consumers and 6,647 lamps. Owing to this increase, it had been found possible to reduce the price of current from 8d. per unit, with discount, to a net 6d. per unit. For motive power, cooking, heating, etc., the directors had decided to supply current at the reduced rate of 3d. per unit, and they anticipated that as soon as it was generally known that current was available for the purposes named a considerable accession of business would result.

The report was adopted, and Messrs. H. Collins and J. C. Fidler, the two retiring directors, were re-elected, and Mr. Geo. May, of The Warren, Caversham, was further elected a member of the Board.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Hamburg.—The Finanz Deputation want tenders for a crane for the electricity works by 26th inst.

The Hague.—The Dutch Colonial Office wants tenders by 27th inst. for the supply of galvanised iron wire for the telegraphic service.

Breslau.—Tenders are wanted by May 27 by the Breslau Stadtbau-Deputation for lightning conductors for a school building.

Mako (Hungary).—The municipal authorities of Makö in Hungary are desirous of receiving proposals for the electric lighting of the town.

Digitized by Google

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadtrath, Prague.

London, S.E.—Tenders are required for complete installation of electric lighting. For particulars apply by letter to Mr. H. Freeman, 44, Knatchbull-road, Camberwell, S.E.

Penaranda de Bracamonte.—Tenders for electric lighting of the town for a period of 15 years may be sent to the authorities at the Casa Consistoria, Peneranda de Bracamonte, Spain, by May 28.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years Tenders should be sent in by August 31.

Santiago de Chile.—The Telegraphic Department of the Chilian Government will receive tenders up to June 6 for the supply of 5,000 glass jars for Leclanché cells and about 3½ tons of sal-ammoniac (pure).

Coblentz.—Tenders are wanted by 30th inst. for the annual supply of 10,000 to 13,000 wooden telegraph poles for four years. Particulars from the offices of the Konigl. Ober-Postdirection, Coblentz, for 30pfg. (3d.).

Lisbon.—The Royal Portuguese Railway Company will receive tenders up to June 3 for the supply of small telegraphic stores. Application to the Chief Engineer, Stores Department, Santa Apolonia Station, Lisbon, and particulars also obtainable at 28, Rue de Châteaudun, Paris.

Paris.—Tenders will be received by the Prefect of the Seine at the Paris Tribunal de Commerce on May 23 for the installation and working for 10 years of the electric light at the Hospice de Brévannes. The estimate is about £5,533, and the maximum annual payment 27,600f. (about £1,080).

Oldham.—The Electric Lighting Committee invite tenders for supplying them with a jet condensing plant capable of condensing 25,000lb. of steam per hour. Copy of specification may be obtained on application to Mr. Arthur Andrew, Gas and Water Offices, Oldham. Tenders to be sent in by 26th inst.

Gisburn.—Tenders are invited for the various works required in erection of new buildings for electric lighting plant and homestead purposes at The Woodlands, near Gisburn, for Chas. J. Massey, Esq., J P. Quantities may be obtained on application to Mr. Charles Parsons, architect, 9 Grimshaw-street, Burnley.

Spandau.—Tenders are wanted at the Royal Small Arms Factory for 900 incandescent electric lamps by July 17 and for 27,300 sets of arc-lamp carbons by June 12. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21), Spandau.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Burton-upon-Trent.—The Council require tenders for the supply of 25,000 tons, or a portion thereof, of best screened gas coal. Forms of tenders and conditions of supply may be obtained upon application to Mr. F. L Ramsden, manager and engineer Gas and Electric Light Works, Wetmore-road, Burton-upon-Trent; and sealed tenders, endorsed "Coal," are to be delivered to the manager at or before 10 a.m. on 27th inst.

Dresden.—The Telegraph Department of the Saxon State Railways want tenders by June 10 for about 50 tons of galvanised iron wire (4 millimetres) and 10 tons of smaller sizes; also 3,700 glass jars (various) for battery cells, and 10,000 porcelain insulators large size and 2,000 of smaller sizes as well as 7.500 zincs for Meidinger and 1,000 for Leclanché cells. Particulars from Die Königl. Magazin-Verwaltung, Dresden-Friedrichstadt.

Aberdeen.—Tenders are required by the Corporation for supplying and erecting boilers, feed-water heater pumps, and piping, for the electricity works extension. Copy of specification, conditions of contract, and form of tender may be obtained and drawings seen at the Electrical Engineer's Office, Cotton-street, on payment of £1. 1s. Sealed tenders, endorsed "Tender for Boilers," and addressed to the Town Council of Aberdeen, to be lodged at the Gas and Electricity Office, Town House, Aberdeen, by 10 a.m. on 27th inst.

Bucharest.—Tenders are wanted by the Municipal Administration of Bucharest by June 24 for a concession for lighting the city for a period of five years. A security of 15,000 lei (about £600) will be required. The Municipal Authorities of Bucharest ask for further tenders up to June 24 for lighting the suburbs and environs "on a system without (underground) pipes more suitable than those that have been already offered." It is desired to replace 3 265 petroleum lamps, and the contract will be for five years. Communications should be sent to the Mairie at Bucharest. Tenders are wanted by the Roumanian Postal and Telegraph Department at Bucharest for the supply of about three tons of sulphate of copper and two tons of sal-ammoniac. Tenders must be in by June 1.

Hammersmith (London).—The Vestry want tenders for the following: (*a*) the supplying and laying of high-pressure and low-pressure cables and pipes; (*b*) the supply and erection of arc lamps and lamp-posts; (*c*) the supply and erection of transformers and sub-station equipment; (*d*) the supply and erection of a five-ton overhead travelling crane. Specifications, general condition, and form of tender can be obtained at the office of Mr. A. H. Preece, 39, Victoria-street, Westminster. Applications for any one or all of the above sections must be accompanied by a cheque for £2. 2s. which will be refunded on receipt of a bona fide tender. Sealed tenders, endorsed "Cables," "Arc Lamps," "Transformers," or "Crane," must be delivered at the offices of the Vestry. 57, Fulham Palace-road, Hammersmith, by noon on 27th inst. Mr. W. P. Cockburn, vestry clerk.

RESULTS OF TENDERS.

Haslingden.—The contract for the installation of the electric light in a portion of the premises of the Industrial Co-operative Society has been let to Messrs. Simpson Bros, of Hapton.

Tunbridge Wells.—For the supply of two large boilers, one small one, and a feed-water heater, for the Lighting Committee, the tender of Messrs. Babcock and Wilcox at £1,497 was accepted.

Hampstead.—Wright's Patent Heater Condenser Company, 16, Great George-street, Westminster, have received the order for the steam and exhaust pipes and feed-water heater for the electric lighting station. Their price was £967, including Berryman heaters with special gear for lifting the casing for cleaning purposes.

Brussels.—The lowest tender on May 13 for alterations in the water supply and electric lighting at the Marbehan Station was that of Messrs. F. Parisse-Gerard, of Thibessart, at 33,777fr.; and for reconstruction work at the electric lighting station and machine shops at Arlon Station the lowest tender was that of Messrs. Bounameaux, of Jemelle, at 79,820fr. The estimate for this was 69,026fr.

Frankfurt a.-Main.—The lowest tenders on May 9 for the supply of telegraph poles 7 metres, 8½ metres, and 10 metres long, were those of J. Himmelsbach, Friesenheim, Baden, at 5·73 marks, 7·30 marks, and 9·30 marks respectively, delivered at Frankfurt-a.-M., and treated with corrosive sublimate, and of the same named firm at Freeburg, Baden, at 4·76 marks, 6·16 marks, and 7 97 marks treated with chloride of zinc and delivered at Gelnhausen.

Portsmouth.—The following tenders were received by the Guardians of the Portsea Island Union for wiring part of the main building of the workhouse for lighting by electricity:

J. R. Penning (accepted)	£52	10	0
Sussex Electrical Company	44	15	0
W. H. Sabine	55	0	0
C. Forbes and Co.	70	12	4
Sotheby and Co.	81	15	0
Sharp and Kent	97	0	0
A. E. Squire	107	15	0
Brown and May	113	0	0

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,375.

Wrexham.—The Board of Trade have revoked the Wrexham Electric Light and Power Order, 1890.

New Address.—The Midland Electric Company have removed to larger premises at 270, Broad-street, Birmingham.

Bangor.—It is reported that a company is about to apply to Parliament for a provisional order to supply the town with electricity.

New Company.—The Blackheath and Greenwich District Electric Light Company, Limited, has just been registered with a capital of £5,000.

Hartlepool.—Major Cardew and Colonel Yorke have visited the neighbourhood and inspected the new electric trams on behalf of the Board of Trade.

Hampton.—At the District Council meeting a draft agreement relating to an electric bell circuit and Mr. Graham's house and the police station was received from the Postmaster-General and approved.

Lead Oxide Company, Limited.—This Company has been registered, with a capital of £20,000 in £1 shares, to carry on business as smelters, manufacturers of and dealers in lead, lead oxides, etc.

Darwen.—At a meeting of a sub-committee of the Town Council the question of the Corporation supplying electric light was considered, and it was decided to engage an expert to go fully into the matter and report.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending May 17 amounted to £1,125, as compared with £1,141 in the corresponding week of the previous year, being a decrease of £16.

Hammersmith.—The Electric Lighting Committee of the Vestry have appointed James George Egan as clerk of works, at 3½ guineas per week, his duties being to superintend the erection of the building in connection with the electric lighting.

Cardiff.—The Electric Lighting Committee of the County Council have resolved to recommend the extension of the mains from the infirmary to Clifton street, and from Canton Bridge along Cathedral-road as far as the corner of Plasturton-place.

Ayr.—The Town Council have been authorised to borrow a further sum of £5,000 for the purpose of capital expenditure under the burgh electric lighting order of 1890. Sir W. Arrol has requested that his mansion may be supplied with the light.

Digitized by Google

Folkestone.—We understand an offer has been made by Mr. William Slingo, representing a London firm of electricians, to take over the provisional order about to be granted to the Council.

Liverpool.—At the Liverpool Finance Committee's last meeting plans were submitted from the Liverpool Electric Light Company for the erection of a chimney 145ft. high in connection with a generating station in Paradise-street. The committee approved of the plans.

Wiring.—Under the auspices of the Electrical Trades Union, Mr. F. Bathurst, of the Interior Conduit Company, is to address the London wiremen on the subject of the "Wiring Question," at the Club Union Buildings, Clerkenwell-road on Wednesday evening next.

Germany —It may be noted that the Allgemeine Elektricitäts Gesellschaft and the Elektron Companies propose to make a considerable increase in their capital accounts. The latter company has interests in common with the Griesheim Electro-Chemical Works.

Mitchelstown.—At a meeting of the Guardians, Mr. Patrick Fitzgerald gave notice that he would on that day month move that powers to light the town by electricity under the Electric Lighting Act of 1881 be vested in the Guardians as the local executive authority.

Aberdeen.—At the meeting of the District Committee, an application by the Northern Electrical Lighting Company, asking permission to lay mains under the Deeside-road from Middleton to Bieldside, was submitted and remitted to the Road Sub-Committee with powers.

Banbury.—A meeting of persons interested in the development of telephonic communication has been held under the auspices of the National Telephone Company, Limited, when Mr. F. W. Taylor, of Reading, district manager to the company, gave an explanation of the scheme.

County of London and Brush Electric Lighting Company.—A second issue of 10,000 preference shares was made last week, and we are informed that applications to over four times the amount offered were received from the public. This fact speaks volumes for the stability of the Company.

Middlesbrough.—At the meeting of the Town Council Alderman Jones moved in favour of the introduction of the electric light, and the immediate laying down of plant at a cost not exceeding £10,000. Mr. Forbes seconded, and the debate, after being carried on for some time, was adjourned.

Fleetwood —Councillor Shuttleworth had been added to the Electric Lighting Committee. The Corporation propose to dispose of their electric lighting order, and, it is said, to Messrs. Bennett and Druce of Preston, who will amply recoup the Corporation for all the expenditure they have incurred in the matter.

New Cable-Laying Steamer.—Messrs. David J. Dunlop and Co., Port Glasgow have launched a twin screw steamer of 750 tons register to the order of the New Zealand Government for cable-laying purposes. The steamer is named "Putanekai," and will be supplied with two sets of triple-expansion engines by the builders.

Arran.—The telephone between Brodick on the east side and Dugary on the west side of the island, which was erected in 1891, has now been thoroughly renewed. New instruments with patent batteries have been fitted up, the whole work having been executed by Mr. Letton, one of Cox, Walker, and Co.'s men from Edinburgh.

Limerick.—Prof. Kennedy, with Mr. William E. Corbett and Mr. Baker, have visited Killaloe with the object of reporting on a site for supplying the city with electric lighting They also visited Doonas and the Clareville Waterworks, where they were met by the Mayor (Mr. Wm. N. Nolan), the high sheriff (Mr. Joseph Gaffney), etc.

City and South London Railway.—The returns for the week ended May 17 were £864, compared with £905 for the corresponding period of last year, being a decrease of £41. The total receipts for the half-year terminating as above were £18 800, compared with £18,720 in the same period of the preceding year, being an increase of £80.

Swansea.—The negotiations between the town clerk and the tramways company in reference to the triple scheme are proceeding satisfactorily. We understand that the engineer to the company, Mr. Kincaid, is instructed to visit Swansea, when a conference will be arranged with him and the Electric Lighting and Tramways Committee.

Appointment Vacant.—The Lincoln Town Council propose to appoint an electrical engineer at a salary of £300 a year, whose duty it will be to design and superintend the carrying out of a continuous-current electric lighting system for the city. Particulars can be obtained on application to Mr. H. R. Hebb, St. Peter's-churchyard, Silver-street, Lincoln.

Hackney.—The Guardians have accepted the recommendation of the Building Committee, who, after consulting with Mr. W. A. Finch, their architect, advised that no further action be taken with regard to the provision of an electric light installation at the new infirmary pavilion. Mr. Beurle fought strongly for the adoption of the electric system, but without avail.

Coatbridge.—A discussion took place at the Council meeting on a recommendation of the committee on acquiring the gas and electric lighting works that an offer of £75,000 be made for the gas company's works, being in their opinion £4,900 in excess of the present value of the shares It was decided, however, by six votes to four, to make no further negotiations in the matter.

Blackpool —Electricity will be largely employed in producing some novel effects in the series of spectacular ballets at the Winter Gardens this season. Mr. Quinn, of Brighton, has been appointed borough electrical engineer at a salary of £300. He was second in command at Brighton Corporation Electricity Works. Mr. Cooper has been appointed assistant to Mr. Quinn at a salary of £130.

Portsmouth.—The consent of the Town Council has been given to the carrying of electric light mains through St. Ronan's-road, at an estimated cost of £200, and it was decided to apply to the Local Government Board for power to borrow £6,000 for various works connected with the extension of the system. This formed part of the general application made some time ago for £20,000.

Telegraphic Communication with Lighthouses.—The Plymouth Chamber of Commerce, in replying to a statement made by the secretary of Lloyd's, insists on the paramount necessity that lighthouses, when built, should be utilised to the fullest extent possible for the saving of life and property by putting them into telegraphic communication with the general telegraphic system of the country.

Yarmouth.—At the meeting of the Town Council the Electric Lighting Committee reported that in April eight additional customers had applied for 388 lamps, raising the number of customers to 168, and of lamps to 7,991. The income for the month was £145. 16s. 8d., and expenditure £129. 11s. 2d. The repayment of capital, interest, etc., now amounts to about £1,000 a month.

International Exhibition.—A Central American international exhibition is to be held in the capital of Guatemala from March 15 to July 15, 1897. Exhibits from any country will be admissible so far as they fall under the heading of science, mechanics, construction, etc. Information may be obtained at the London Chamber of Commerce, Eastcheap, E C., between the hours of 10 a.m. and 5 p.m.

Edinburgh.—Arrangements have been made with the Post Office authorities by which the subscribers to the National Telephone Company's local exchange system may telephone their telegrams direct to the Post Office by means of the exchange instruments fixed upon their premises. Telegrams may also, where the Post Office regulations permit, be transmitted from the post office to subscribers in a similar manner.

Carlisle.—At the meeting of the Town Council Mr. Buck asked what position the Gas Committee were in with regard to the electric light Mr. Corbett said the provisional order had been obtained, and at an early date the committee would be in a position to report upon the question They had no intention of letting the matter sleep. Barring the new supply of water, it was the most important matter the committee had under consideration.

Cardiff.—At a meeting of the Tramways Committee Councillor Robinson urged the committee not to make any agreement which did not allow of the use of electricity, and quoted figures to show that in America electricity was fast displacing horse-power as a motive power for tramcars. The Chairman explained that the tramway directors had expressed their willingness, if it seemed advisable, to take the electric power from the Corporation.

Luton.—The Electric Lighting Committee reported at the Town Council meeting that they had elected Councillor Green as chairman. They had also resolved that the Town Council should become a member of the Municipal Electrical Association for one year, and the town clerk is to remit the fee of £1. 1s. Councillor Wilkinson was appointed to attend as a delegate at the annual convention of the association on June 10, 11, and 12. The report was adopted.

New Electric 'Bus Company.—The London Electric Omnibus Company, Limited (Ward's system), has been formed with a capital of £250,000 in £1 shares, of which 170,000 are now issued, to take over from a syndicate the patents relating to Mr. Radcliffe Ward's system of electric street traction. The price under which the Company acquires the exclusive license for England for the patents is £100,000, of which £20,000 will be paid in cash, and the balance in fully-paid shares.

Morecambe.—Mr. Bellamy moved at the meeting of the District Council that a committee should be appointed to look out for a site for electrical works for supplying electric light, to suggest a scheme for supplying the light, and prepare for application to the Board of Trade and the Local Government Board, with power for the committee to visit electrical works. He practically moved the reappointment of the old committee, but it was eventually decided that the committee should comprise the whole Council.

Skye.—The telegraph is about to be extended to Staffin. Mr. Baillie has received the following letter from the Scottish Office: "With reference to previous correspondence respecting the extension of the telegraphic system to Staffin, I am directed by the Secretary for Scotland to state for your information that provision has been made out of the vote for the year 1896-97 for public works and communications in the highlands and islands of Scotland for the purpose of carrying out this extension."

Brown, Boveri, and Co.—We have received from Messrs. Brown, Boveri, and Co, of Baden, Switzerland, and Frankfurt-on-the-Main, an illustrated description (in German) of their alternate-current (single-phase) motors, with particulars and testimonials relating to the installations made by them or in which their machines have been used. The book is in the usual square catalogue form, but it would be hardly right not to mention the tasteful way in which the colour-printing is done, or the excellence of the process-prints of the machines.

Helmington Row.—The question of lighting was brought up at the Parish Council meeting. The Chairman said it was hopeless to expect that they could get gas, as the Crook Company had

Digitized by Google

absolutely refused them it. Mr. Gaines thought they had better go in for the electric light. Messrs. Straker and Love had ample plant at Sunnybrow to supply the whole district. Mr. Steele said there was ample power; all that was necessary was the cable putting in. Ultimately the question was referred back to the committee to make further enquiries.

Wakefield.—At a joint meeting of the Sanitary, Sewerage, and Electric Lighting Committees of the Corporation for the purpose of opening the tenders sent in for the new electrical works in Calder Vale, the tender of Messrs. Holme and King, of Liverpool, at just over £8,000, was accepted for the bulk of the buildings. Several from local tradesmen were accepted for minor portions of the work. The contract for a chimney shaft 180ft. high has been let to Mr. William Thickett, of Horbury, for £2,532. 7s. 9d The loan borrowed for the works amounts to £25,000.

Oldham.—At the meeting of the Corporation Alderman Goodwin proposed that the standing orders be suspended in order that the minutes of a meeting of the Technical Education Committee containing a resolution that the contract for wiring for the electrical installation be let to the firm of W. A Shaw and Co., of Stockport, might be considered. He added that the firm had done good work in the town, and for the Corporation, in the past, and their tender had been considered the best out of about 30. The orders were suspended, and the minutes were unanimously approved.

Birmingham. — Mr. William Mackenzie, president of the Toronto Railway, and Mr. James Ross, managing director of the Montreal Street Railways, have made an offer to purchase the business of the Central Tramways on the basis of par value for debentures and preference shares, and a bonus of £1 on the ordinary shares, which were originally £10, but two years ago were written down to £5. The total amount would be about half a million. In a circular which the directors have issued they warmly commend to the shareholders acceptance of the proposal.

Burton.—At a meeting of the Town Council two letters were read from Mr. Aston Webb, the architect for the rebuilding of the infirmary, asking if the infirmary could be supplied with electric current in a year's time, if the main could be brought to the building. and what the cost of the current would be. The Council replied that the supply would be afforded at the usual price, and for the cost of any extension of service lines upon private property. The manager has been instructed to obtain and fix two additional transformers on the High and Station streets electric light mains, at a cost of about £100.

Watford.—In accordance with notice, Councillor G. P. Neele moved, at the Urban District Council meeting, "that steps be at once taken by the Council to obtain the needful legal authority for the introduction, under their control, of the system of public electric lighting into Watford, it being then left for subsequent discussion whether the Council will retain the working in their hands or transfer (under the provision of the Electric Lighting Act) the liability to a local company or syndicate." In doing so he spoke of several places where it had been successfully taken up Councillor Pridmore seconded, and the resolution was carried.

Southend.—The Highways and Works Committee recommended at the Town Council meeting, the lighting of the whole town with incandescent gas lamps for a period of three years at an increased annual cost of £272. 15s. 10d. Councillor Bowmaker (chairman of the Electric Lighting Committee) strongly opposed the recommendation. The report from Prof. Robinson, he said, had just arrived, and he asked for time for its consideration. This haste was unseemly; it was grossly unfair to the Electric Lighting Committee. He moved that the question be adjourned for six months. In the end the report of the committee was adopted.

Gulcher Electric Light Company.—Mr. C. Fitch Kemp, the liquidator of the Gülcher (New) Electric Light and Power Company, has issued a final report, from which it appears that there is no reasonable prospect of paying the second debentures in full unless a claim on the New Zealand Electrical Syndicate can be realised, as to which he is not hopeful. He recommends that an offer of Lloyd's Bank to take over the liabilities and assets of the Company should be accepted, but desires to take the sanction of the creditors and contributories before accepting it. A meeting for that purpose has accordingly been called at 73, Lombard-street, at 12 o'clock on May 26.

Dewsbury.—A deputation from the governors of the Dewsbury and District Technical School, consisting of M ssrs. S J. Chadwick, C. B. Crawshaw, and F. W. Reuss, has waited on a committee meeting of the Town Council, and asked that the committee would lay down the necessary mains for supplying the technical school with the electric light. Consideration of the subject was deferred to a special meeting. The Council have decided that the fittings for the electric light for the new baths and library should be made for a voltage of 220, instead of 110, at an extra cost of £11. The deficiency on the electric lighting account for the year ended March 31, 1896, is £385. 7s 3d.

Sunderland.—At a meeting of the Town Council Alderman Bruce proposed the adoption of the Electric Lighting Committee's report, which was to the effect that on and after October 1 next the terms for the supply of electrical energy for lighting purposes be reduced by 1d. per Board of Trade unit – viz., from 6d. to 5d.— with the same discounts as heretofore During the past year 95,446 units of electrical energy had been produced at the Corporation station, for the support of which £701 had been taken from the rates. This sum, however, could not be reckoned as a loss, for the buildings were not yet paid for. It was intended to largely increase the service during the ensuing few months. The report was adopted.

Kingswood.—At a meeting of the District Council a communication was read from Messrs. Parfitt, electric light contractors to the Council, offering for sale the whole of the present installation in the Kingswood district. The letter further suggested that now was a good time for extending the light, if the Council was so disposed. Mr. Peacock said he quite agreed with Messrs. Parfitt that if they intended to have an extension of the light, it should be commenced at once, before the winter came on. The Chairman asked whether the Council would not do better by waiting a little longer. After further discussion, the matter was referred to the Lighting Committee.

Municipal Electric Association.—The first meeting will be held on Wednesday, June 10, in London. On that day Mr. Arthur Wright will deliver his presidential address, and papers will be read by Mr. A. S. Barnard (Hull), Mr. H. W. Couzens (Taunton), Mr. C. H. Wordingham (Manchester), and Mr. A. B. Mountain (Huddersfield). On the following day papers will be read by Mr. Arthur Wright (Brighton), Mr. J. A. Jeckell (South Shields), Mr. E T. Ruthven Murray (Worcester), and Mr. J. Hesketh. Friday morning will be devoted to a business meeting, after which, a visit will be made to Brighton, when a paper will be read by Mr. A. H. Gibbings (Bradford), and the Corporation electricity works will be inspected.

Brighton.—The Lighting Committee recommend the acceptance of the tender of Messrs. Skeats and Co, Queen's-road, to put up 450 street gas-lanterns for incandescent electric lamps for £180 and 8s. for each additional lamp. It is recommended that the electricity main be taken up Islingword-road as far as No 126, and that the street lamps in that road to that point be fitted with incandescent electric lights. Portions of Eaton-place and Carlton-hill are to be similarly lighted. The Bill which extends the time for the completion of the Brighton and Rottingdean Seashore Electric tramroad has been referred to the Unopposed Bill Committee of the House of Lords. This Bill has already been sanctioned by the House of Commons.

Dublin.—The tramways were opened for traffic last Saturday, and met with extraordinary success. Large crowds availed themselves of the new means of transit, and although there were 28 cars in the service this number was not at all equal to the traffic, and people had to wait in some instances nearly an hour before they could get seats. The cars ran smoothly and without the slightest hitch, and everything in connection with the traffic promises well. There was no formal opening ceremony. except that the Lord Mayor drove the first motorcar from Dalkley to Dublin. We regret that, owing to its late arrival, we were unable to reproduce the photograph of Mr. H F. Parshall, the consulting engineer, in our description of the tramways last week.

Sussmann Electric Miners' Lamp Company, Limited.—This Company has been formed with a share capital of £80,000 in 39,250 7 per cent. cumulative preference shares of £1 each, 39,250 ordinary shares of £1 each, and 1,500 deferred £1 shares, to acquire the various British, foreign, and Colonial patent rights for the Süssmann lamp, which is a portable electric lamp for coal and gold mines, and to supply it to large users. Subscriptions were invited for an issue of 31,750 preference and 31,750 ordinary shares. The purchase price has been fixed at £45,000. payable as to £10,000 in cash, out of which the expenses of this issue will be defrayed, £1,500 in deferred shares, and the balance either in cash or shares, or part of each at the option of the directors.

Bury St. Edmunds. — The Electric Lighting Committee appointed last October have completed their report. This has been printed, but will not be published until it goes before the Council in the middle of next month It may be said, however, that the final decision of the committee is to recommend that mains for private supply should be laid over an area comprising the centre of the town, and that a three-wire continuous-current system at the higher voltage (200 volts) should be adopted. It is further recommended that the public lighting should be undertaken throughout the whole of the borough, for which about 450 16 c.p. incandescent lamps and four arc lamps will be required. The total estimate is £21,400. Mr. F. H. Medhurst is the consulting engineer.

Ashton.—The electric tramways company appear to be inclined to co-operate in a very friendly way with the Corporation. The company suggest that they and the Corporation might work into each other's hands to the mutual advantage of both. Both the Corporation and the company have been contemplating the erection of generating stations, and the company suggest that the whole thing might be arranged under one roof. They suggest that the company should be supplied with power by the Corporation, and of course this would add considerably to the capital outlay of the Corporation in connection with their installation, but the company may not be able to wait for the slow operations of the Corporation in this matter. The suggestion may accelerate their rate of progress.

Guildford.—At the meeting of the Town Council a letter was received from the Board of Trade enclosing a letter which the Board had received from Mr. Folkard, secretary to the Guildford Electric Light Company. The letter stated that the details of the method in which the main cables were to be laid having been now settled, the company had given notice to the authorities and were now prepared to take up the streets with a view of laying down the mains, and also to deposit the stipulated £500. They therefore asked the Board to allow the company to make an immediate start on the mains. The number of shares actually allotted was 979, with a promise of another 100, which more than covered the first contract for the work, which covered all the mains in the scheduled streets.

Calcutta.—The *Indian and Eastern Engineer* says there is very little foundation for the statement that the Calcutta Tramways Company have arranged to work their cars by electric power. It seems that negotiations with an English firm have been carried on with this object in view, but the existing track is in such a condition that it would have to be entirely relaid with modern rails before electric traction could be applied with any chance of success. An offer, we are told, has been made to the company to take over their property, but how far this is the case we are unable rightly to ascertain. This much we can affirm, that Calcutta is, in respect of her tramway system, as much behind the age as in every other matter which pertains to the good of the city and the convenience of its population.

Whitehaven.—At the Town Council meeting it was reported that at a meeting of the Water and Lighting Committee on April 14, a letter having been read from the Harbour Commissioners stating that they had resolved to rest on the existing agreement for the lighting of the harbour by electricity, also read the resolutions of the trustees of the town and harbour, dated July 25, 1893, it was resolved that the Council carry out the terms of the existing agreement, and the surveyor was instructed to do what was necessary for that purpose. The engineer read correspondence which had passed between himself and Messrs Siemens Bros. as to the cost of opening and closing the trenches in connection with the renewals of defective cables. At a subsequent meeting a letter was read from Dr. Hopkinson expressing his opinion on this subject, and the town clerk was instructed to communicate further with him and report to the committee.

Horseless Carriages.—The Great Horseless Carriage Company, Limited, with a capital of £750,000, has been formed to carry on and establish the great horseless carriage industry in this country. Extensive works, the prospectus states, with railway and canal adjoining, have been secured at Coventry. The company acquires the sole license to build horseless carriages for the Daimler Motor Company, and will work under a full license to manufacture and use the great systems now perfected, including the Pennington motor inventions Count de Dion and Mons. Bouton's improvements in steam and electricity, Garrard and Blumfield's electrical car improvements, the Universal Electric Carriage Syndicate's patents, Mons. Bollee's patented autocar, the advantages of all the Daimler motor patents, and certain inventions of Harry J. Lawson and J. J. Henry Sturney, Henry P. Holt, and others. The consideration to be paid by the company to the British Motor Syndicate, Limited, is 50,000 shares or cash in lieu thereof.

Mumbles Railway.—The directors of the Swansea and Mumbles Railway have received an exhaustive report from Mr. Morgan Williams, M.I.C.E, M.A., on a proposal to utilise electric traction instead of steam on the line The report is based on the presumption that the Corporation would supply the current necessary on an agreed price of 2d. per unit up to 600 000 units, and 1½d. up to 750,000 units; and that the Corporation lend the money for the conversion and equipment of the track, charging 3 per cent. interest on the money so employed, and a sinking fund to repay the loan within 30 years. He concluded that the price of electricity would prove dearer than steam, and the charge to bring these equal would have to be 1·29d. per unit instead of the amount proposed. Under these circumstances he does not think with the somewhat limited opportunities of obtaining detailed information that he had had, it would be advisable to undertake the conversion of the line from steam to electricity unless materially better terms were obtained from the Corporation

Exeter.—At the meeting of the City Council the Special Committee on Electric Lighting recommended that the town clerk be given counsel's assistance in drawing up the conveyance of the works to the Council, that £299. 19s. 10d. be paid to the company for extra plant, that the surveyor be requested to report to a meeting of the committee on the work necessary to be immediately undertaken in order to increase the power and efficiency of the present works, that it be recommended to the Council that it be referred to the committee to consider and report upon the arrangements which should be made for the future management and control of the undertaking, and that the secretary to the hospital be informed that from June 30 next the undertaking of the electric light company would be in the hands of the Council, and that it was the intention of the Council to run the works so as to give a supply of light throughout the whole of the 24 hours of the day, and that the Council would be prepared to make special terms with large consumers such as the Devon and Exeter Hospital. The report was adopted.

Taunton.—The Electric Lighting Committee presented the following report at the meeting of the Town Council: "Your committee report that the cables in connection with the No. 3 substation, also the arc cables, have been laid and tested by Dr. Fleming; he has also tested the transformers, and will shortly report as to the results of such tests." Alderman Potter, in proposing the adoption of the report, remarked that the committee were extremely well pleased at the expeditious and careful manner in which the work mentioned in the report had been carried out. No stones were "ruthlessly broken," but the whole thing was done in the most careful manner possible, and the thanks of the Council were due to the men for the way in which they did the work. Alderman W. H. Fowler seconded the motion, which was agreed to. The Borough Surveyor reported that the No. 3 substation for the electric light had been formed in a cellar under Mr. Councillor Sibley's shop at East Gate, the whole being made as far as possible fireproof. The entrance was made with an opening in the pavement and covered with prismatic lights in flaps, balanced so as to be easily lifted. The transformers were now in use.

Appointments Vacant.—The Corporation of Wakefield require the services of a competent person to act as clerk of works during the erection of the electricity works. Applications, in own handwriting, stating age, experience, and wages required, to be sent not later than Wednesday, May 27, 1896, to Mr. Richd Porter, city surveyor, Town Hall, Wakefield.—A practical working engineer is required for the Royal Asylum, Aberdeen. He must have a thorough knowledge of electricity, and be capable of taking full charge of steam boilers, Dowson gas plant and gas-engines, etc. Written applications only, with recent testimonials as to ability and character, to be sent to the medical superintendent by 23rd inst. Salary £2 per week outdoor.—The Improvement Committee of the Sheffield Corporation require the services of a practical engineer, with a knowledge of electrical fittings, to take charge of the boilers and the whole of the heating apparatus and electrical fittings in the town hall, and to perform such other duties as may be required. An engine-tenter or fireman will also be employed. Applications, stating age, salary required, present occupation, and previous experience, to be sent to Mr. Herbert Bramley, town clerk, Sheffield, with copies of not more than three testimonials (which will not be returned), by 23rd inst.

City and South London Railway.—The Bill promoted to extend the time for the purchase of lands for the purposes of the City and South London Railway Act, 1893, and for the completion of the underground railway and other objects came before a Select Committee of the House of Commons last week. The main question before the committee was the demolition of the church of St. Mary Woolnoth, in King William-street, near the Bank of England, for the purpose of erecting a station. Amongst other witnesses called was Mr. C. G. Mott, chairman of the company, who said the church was not wanted. There were 10 churches within a radius of 200 or 300 yards two of them being actually in the same street as St. Mary's. Besides, St. Mary's had no congregation and there were no peculiar associations connected with it. It merely resembled a room in the Mansion House. The money that would be paid for it would be sufficient to enable several other churches to be built in districts where churches were wanted and where congregations could be easily obtained. If the church were left standing the company would not have as useful a station as would otherwise be secured, and the cost of the works would be increased. The committee found the preamble of the Bill proved, subject to the insertion of a clause for the protection of St Mary Woolnoth, and declaring that it shall be referred to the arbitrator to take into consideration the additional liability which will devolve on the company in consequence of giving up their present rights.

Glasgow.—At a meeting of the committee having charge of the clocks in the city a report was submitted by Prof. Becker, who for the past six months has been experimenting at the observatory with electric clocks, with the view of an installation to give uniform time to the entire city. The committee agreed to recommend to the Corporation the removal of the installation working at the observatory to the Municipal Buildings, from which, by way of experiment, a central area with 10 wall timepieces will be worked. Should the experiment prove satisfactory, the installation will be extended throughout the entire city. A report is before the Sub Committee on Electric Lighting. According to the statement the continuous and alternating current systems are equally good for lighting the city, but for tramway motor purposes it is absolutely necessary to adopt the continuous current system owing to the Board of Trade stipulations The system recommended by the report for Glasgow, where the demand for the current will be largely concentrated within a given area, is a continuous current of 500 volts, which could be supplied direct to the street lamps and the tramways without any complications in transformers; and while the area over which 500 volts could be maintained at a constant supply from the present works is only 1½ miles, it is pointed out that three large works—two on the north side of the river and one on the south—would be sufficient to meet the requirements of the city for many years to come. The present station at Waterloo-street, it is added could be utilised until the demand on the new works enabled them to run full time.

Southampton.—It was reported at the Town Council meeting that the National Telephone Company had written to the effect that they had under consideration the question of making certain alterations to, and improvements in, their plant in Southampton, and, amongst other things, of placing the system on what was known as the twin-wire or metallic return principle, which involved the provision for each subscriber of a second or return wire. To do this effectively, and to secure the greatest efficiency of service, it was essential that the main routes of wires in the centre of the town should be placed underground, and the co operation of the Council in the matter was sought. The letter was referred to the Works Committee The Electric Lighting Committee recommended the payment to Messrs. Kincaid, Waller, and Manville of £52. 10s. for their report, etc., on the electric lighting undertaking. Mr. E. Manville had attended and conferred with the committee generally upon the electric lighting question, submitting plans of the proposed new buildings, of which the committee approved, subject to the acquirement of the extended site required. The committee having visited the works, subsequently proceeded to Portsmouth, where they were very kindly escorted over the electric light works of that borough by Alderman Ellis, the chairman of the committee, and also by the deputy-chairman. The deputation also inspected the most important thoroughfares where the electric lighting mains had been laid down. Alderman Bone thanked the Portsmouth committee for their kindness and courtesy. The report was adopted without comment, on the motion of Alderman Bone.

Dundee.—The Institute of Engineers paid a visit of inspection to the electricity works last week. The company, which numbered about 40, was divided into two parties, and escorted over the premises by Mr W. H. Brownlee, manager, and his assistant, Mr. Tittinsor, both of whom explained the various machines and appliances used in generating and supplying the electric light. A vote of thanks, proposed by Mr. James Anderson, to the manager and his assistant for their kindness and courtesy, terminated a most enjoyable visit. Owing to the rapidly increasing number of subscribers in Dundee and district, the Telephone Company have resolved upon an important change in the numbering of the instruments At present the telephones on the Dundee centre are numbered from 1 onwards; the Broughty Ferry instruments begin at 1,200; those in Newport at 1,400; in Monifieth at 1,500; in Downfield at 1 600; and in Carnoustie at 1,700; the Dundee figures being resumed at 2,000. This system has not been found to be altogether satisfactory either to operators or subscribers. It has therefore been decided that each of the district centres already enumerated will be kept separate, the numbers in each beginning with 1, and the distinction being made by the subscriber intimating to the exchange with which of the districts he desires connection. For the sake of brevity, however, it will be sufficient to name simply the initial letter of each town. These changes will not take effect until the issue of the new directory on July 1. An exchange is in process of construction in Tayport, and will be in operation in the course of a few weeks. The new numbering will here apply equally with the other districts.

Leeds.—The Tramways Bill came before the Committee on Unopposed Bills, with Mr. J. W. Lowther in the chair, and the Standing Order of the Legislature having reference to the working of tramways by municipal corporations having been already suspended, there remained no obstacle to the passing of the Bill, which was passed with a few minor alterations which do not affect the main provisions of the measure. The effect of the Bill is to enable the Corporation to borrow £407,000 for tramway purposes, and to work the lines themselves Councillors C. H. Wilson and Clarke were present as representing the Parliamentary Committee, Councillor Hannam representing the Highways Committee, and the town clerk (Mr. J. Harrison) and the city engineer (Mr. T. Hewson). Mr. T. R. Leuty, M.P, also attended. It was reported at a meeting of the Tramways Committee that the profits derived by the Corporation out of the working of the tramways for the year ended March 25 last amounted to over £4,000. It was decided to extend the penny stage in the small cars on the Headingley route from Blackman-lane to Reservoir street; also to advertise for tenders for the erection of a power station, for bracket poles and overhead wires, engines, boilers, tramcars, and for all that will be required for the electrical tramway from Kirkstall to Roundhay. Alderman Harding has presented a scheme to the Corporate Property Committee for dealing with the open space known as City-square. He suggests that electric light should form part of the scheme of decoration, and that two bronze standard lamps should be provided at a cost of £500 and eight life-size bronze figures holding single glow lights of 500 c.p. at a cost of £1,000

Bath.—A deputation attended at the Board of Trade Office last week, consisting of the Mayor, Aldermen Jolly and Sturges, and Mr. E. W. Morris, also the clerk surveyor, and Mr. G. J. Moger, parliamentary agent for the Authority, and Mr. S. Morse, Mr, T. O Callender, Mr. E Pitman, Mr. B. Wood, and others, for the company. Sir Courtenay Boyle presided, there being also present Major Cardew and Prof. Kennedy. Sir Courtenay Boyle invited Mr. Morse to make a statement, when he urged that the Authority should take over the whole of the arc lighting plant, and pay a sum set down in the company's books for promotion money Mr. Hammond, on behalf of the Authority objected to the arc lighting plant, and to the payment of any money for preliminary expenses. Sir Courtenay Boyle stated that the Board of Trade considered the report of Prof. Kennedy to be a fair one, and that the Authority should not be asked to take over the arc plant, and asked for particulars of the preliminary expenses. He intimated that the Board would grant an order to the Authority upon its undertaking to apply for a loan to carry out the purchase at the price authorised by the Authority. The question of preliminary expenses was left to the president; Mr. Morse to furnish particulars. A special meeting of the Electric Light Committee was held subsequently to consider the report of the deputation. The matter was fully discussed, and attention was given to the new apparatus that will be required to improve the present plant at the works. A special meeting of the Urban Sanitary Authority is to be held to-day (Friday) to discuss the amount of the loan required, which will be considerably in advance of the sum at which the works may be purchased under Prof. Kennedy's valuation.

The Great Tramways Scheme.—At the meeting of the London County Council, the report of the Highways Committee was considered. This report recommended that the County of London Tramways Syndicate should be informed that the Council, having given full consideration to the proposals of the syndicate, was not prepared to enter into any arrangement with the syndicate with reference to the tramways in the county of London. The scheme of the syndicate contemplates the immediate transfer to the Council of all the tramways in the county of London, and the subsequent leasing of the whole by the Council to a company to be formed by the syndicate, the length of the lease to be 28 years from the time of purchase. The Highways Committee also reported in favour of the Council adopting an arrangement for the purchase for £540,000 of the tramways of the North Metropolitan and the London Street Tramways Companies within the county of London. Earl Russell, vice-chairman of the committee, asked that any discussion on the merits of these proposals might not be taken until the second meeting of the Council after the Whitsuntide recess. The committee were still considering the matter, and a further report would be brought up on the subject. As, however, an amendment stood on the paper to refer the syndicate's proposals to the Finance Committee, with instructions to consider and report as to their financial bearing, he would ask that that might be disposed of Mr. A. Hoare then moved, and Mr. N. Robinson seconded, the amendment referred to. The Earl of Onslow hoped that if the amendment was passed it would not be taken as a precedent. He deprecated any action on the part of the Council which would tend to lessen the weight of responsibility which fell on the members of spending committees. This amendment really meant that they were going to allow the Finance Committee to review a proposal which had been rejected by the spending committee. It was making the Finance Committee a sort of court of appeal. He should certainly vote against the amendment. Mr. B. L. Cohen, M.P., fully endorsed what the previous speaker had said. At this stage the debate was adjourned.

Chester.—The electric light buildings are now fairly started. The foundation-stone was laid on Tuesday afternoon by the mayoress (Mrs. B. C. Roberts) who was presented with a silver trowel by Mr. John Jones (deputy chairman of the Electric Lighting Committee) on behalf of Prof. Kennedy, the engineer. The stone bore the following inscription: "City of Chester, Electric Light Station. This stone was laid by the Mayoress (Mrs. Benjamin Chaffers Roberts) on the 19th day of May, 1896. Alexander B W. Kennedy, M Inst.C.E, engineer; Thomas Parker, Limited, contractor." The question of lighting the city has been before the Corporation for about five years, and among the experts who have been consulted are Dr. Hopkinson, F.R.S., Lord Kelvin, Mr. W. H. Preece, and others. Prof. Kennedy is the present consulting engineer in the matter. The tender of Messrs Thos. Parkers, Limited, Wolverhampton, which was selected out of 13, has been expanded, the consulting engineer considering that any installation for Chester should be such as to allow of the enlargement of the area of supply beyond the compulsory area first contemplated. Messrs. Parkers have agreed to run the machinery, to maintain the works, and, in fact, act as the suppliers of the electric light for a period of three years, and at a price which will be remunerative to the Corporation and within the means of the public. In the three years, any defects in the lighting or machinery will be seen, although the Corporation have the right of taking over the concern at any time on payment of a certain amount to Messrs. Parkers. The works, which are in Crane-street, will be erected in the Renaissance style, with a frontage to the street of 94ft. In front will be the offices and accumulator and meter rooms, while the engine and dynamo rooms and the boiler-house will occupy the space behind, the coal stores being in the absolute rear. The engine-room will be lined with brown glazed brick dado with white glazed brick above. At the side of the building an inclined road is to be made above the coal-stores, so that loads of coal can be tipped. The flues from the boilers pass through a Green's economiser to the chimney, which is to be 140ft. high and 7ft. in diameter inside. Altogether, the building itself will cost about £6,000, and will in all probability be finished in about five months. The architects are Messrs. J. H Davies and Son. The committee have arranged for 40 arc lamps to be erected in the main streets at once, and the lighting of the minor streets will be done more gradually.

London Extensions.—The report of the Highways Committee presented at the last meeting of the London County Council contained a statement that an intimation had been received from the Board of Trade that the application of the Vestry of Newington for a provisional order in respect of that parish would not be proceeded with. Sanction was given to the Post Office authorities to construct a 1½in. pipe connection with the troughing which carries the Post Office telegraph wires in Northumberland avenue subway opposite the Royal Colonial Institution; sanction was also given to Messrs. Ellington and Woodall, on behalf of the London Hydraulic Power Company, to lay mains in Banner-street and Leonard-street, St. Luke's, and to lay a branch from the company's main in the Queen Victoria-street subway through the bottom of the subway for the purpose of supplying hydraulic power for working the tunnelling shields used in the construction of the Waterloo and City Railway now being formed at a lower level in that street. The following notices under the Electric Lighting Acts and Orders were approved: the County of London and Brush Provincial Electric Lighting Company, to lay mains in Keswick-road, West-hill and West-hill-road; the Metropolitan Electric Supply Company, to lay mains in Upper St. Martin's-lane, Tower-street, Little Earl-street, Bloomsbury-street, and Shaftesbury-avenue; the House-to-House Electric Supply Company, to lay high and low tension mains on the south side of Redcliffe-square; the London Electric Supply Corporation, to lay trunk mains, consisting of lead-covered concentric cables drawn into cast-iron pipes, in Rotherhithe New-road and Bush-road, across St. James's-road, and in Lucey-road and Rouel-road, Bermondsey; the Westminster Electric Supply Corporation, to lay mains in Mount-street, South Audley-street, Grosvenor-square (two sides), Brook-street, Gilbert-street, Robert-street, and Davies-street; in Union-street, Hanover square, South Molton-lane, Davies-street, Berkeley-square, and Hay-hill; and in Eccleston place and street, Buckingham Palace-road, Ebury-street, Upper Grosvenor-gardens, and Grosvenor-place; and the Vestry of St. Pancras to lay mains in Albert-street. Notice had been received from the Vestry of Hampstead, given in accordance with the provisions of the Hampstead Electric Lighting Order, 1892, of intention to lay mains in and across Abbey-road. The

Vestry is the undertaker under the order, and the Council had no power of approval or disapproval of works.

PROVISIONAL PATENTS, 1896.

MAY 11.

9950. Improvements in electrical arc lamps. William Harding Lauder, 33, Blessington-street, Dublin.

9960. Improvements in electric bell communication. Frank Helman and John Carroll, Liverpool Reform Club, Dale-street, Liverpool.

9964. Improved electric cables. George Hinde Nisbett, 15, Water-street, Liverpool.

9974. Improvements in and connected with electrical switches. Max Binswanger and Francis George Bell, 73, St. Stephen's-road, Upton Park, London

9975. Improvements in and relating to conduits for electrical conductors. Frederick Bathurst, 73 St. Stephen's-road, Upton Park, London.

9976. Improvements in hand telephones and in compound switches therefor. Max Binswanger and Francis George Bell, 73, St. Stephen's-road, Upton Park, London.

9992. Improvements relating to electric traction. Herbert James Allen, 24, Southampton buildings, Chancery-lane, London.

10015. Improvements in writing telegraphs. Richard Joseph Crowley and Alfred Blandford Hutchings, 6, Bream's-buildings, Chancery-lane, London

10017. Improvements in electric arc lamps. William James Davy, 40, Chancery-lane, London.

MAY 12.

10047. System of and means for electrical transportation. Philip Koesuth Stern, 55, Chancery-lane, London. (Complete specification.)

10069. A new or improved method of and apparatus for electrically controlling or adjusting the position of rudders, guns, signals, and other devices. Mathias Pfatischer, Norfolk House, Norfolk-street, London

10095. Improvements in electric batteries. Paul Schmidt, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10096. Improvements in arc electric lamps. Alvie Oscar Mackin, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10106. Improvements in step-by-step printing telegraphs Walter Samuel Steljes, 24, Southampton-buildings, Chancery-lane, London.

10124. Improvements in systems of distribution of alternating electric currents. James Devonshire, 70, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

10127 Improvements in electric tram trolleys. Henry Harington Leigh, 22, Southampton-buildings, Chancery-lane, London. (Herbert Rudolph Keithley, United States) (Complete specification.)

10134. An improved system of and apparatus for the collection of electricity from overhead conductors and in conduits connected therewith. William John Brewer, 1, Queen Victoria-street, London (Complete specification.)

MAY 13.

10171. Improvements in thermostatic circuit closers for electric fire and heat alarms. Frederick Dresser, 20, Bixteth-street, Liverpool.

10189. Improvements in carbon brush holders for electromotors and dynamos. Frederick Henry Royce and Ernest Alexander Claremont, 53, Arcade-chambers, St Mary's-gate, Manchester. (Complete specification.)

10205. An improved tumbler or lever action switch for electric power or light. F. W. Heaton, H. Smith, and A. Lindley, Salford Switch Works, Sidney-street, Salford, Manchester.

10267. Improvements in electrodes for galvanic batteries. Carl Hoepfner, 45, Southampton-buildings, Chancery-lane, London.

10272. Improvements in dynamo-electric machines. Haydn Thies Harrison, 46, Lincoln's inn-fields, London.

MAY 14.

10284. A new and improved reflector in connection with glass bulbs or glow lamps for electrical lighting. George William Pridmore, Thomas John Sturgeon, and Edwin Yorke, 2, Broad-street-buildings, Liverpool-street, London.

10349. A process of preparing metals for galvanic, electrolytic, and for other purposes. Alexander Melville Clark, 53, Chancery-lane, London.

10358. An improved system for registering or storing electric currents and for reconstituting and delivering the currents so stored. Henri Carbonnelle, 6, Lord-street, Liverpool.

MAY 15.

10414. Improvements in electric hoists. William Harding Scott, Gothic Works, Thorpe Hamlet, Norwich,

10415. Dynamo-electrical collecting apparatus. William Sillery, 7 Henblas-street, Wrexham.

10429. Improvements in holders for electric glow lamps. Thomas Richard Davis Kenny, Sunbridge-chambers, Bradford.

10442. Improvements in arc lamps. William Reginald Ridings, 76, Alexandra-road, Edgbaston, Birmingham.

10455. Improvements in electric motors. Richard Norman, 14, The Goffs, Eastbourne.

10456. Improvements in electric motors and their arrangement. Richard Norman, 14 The Goffs, Eastbourne.

10472. An improvement in active material for secondary voltaic batteries. George Annesley Grindle, 28, Southampton-buildings, Chancery-lane, London.

10497. Improvements in or relating to electric traction. John Perry and Thomas Tomlinson, 322, High Holborn, London.

MAY 16.

10608 An improvement in tumbler electric switches. The Edison and Swan United Electric Light Company, Limited, and Charles Faraday Proctor, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

NOTES.

Society of Arts.—The conversazione of the Society of Arts has been fixed for June 17 at the South Kensington Museum.

Prof. Elihu Thomson.—We are sorry to see from an American paper that Prof. Elihu Thomson has got thrown off a bicycle and broken his ankle.

Reade Lecture.—The Reade lecture at Cambridge on June 10 is to be delivered by Prof. Thomson, and will be on the subject of the "Röntgen Rays."

Another Exhibition.—There is to be an exhibition in Lisbon next year in celebration of the fourth centenary of the discovery by the Portuguese of the Cape route to India.

Royal Institution.—It is announced that there will be an extra Friday evening meeting of the members of the Royal Institution on June 19, when Mr. Thomas C. Martin, of New York, American delegate to the Kelvin jubilee, will deliver a lecture on "The Utilisation of Niagara" (with illustrations).

Dublin Tramways.—Last week in shunting a Ballsbridge electric tramcar over from one line to the other at the corner of Haddington-road, Dublin, where the system joins that of the Dublin United Tramway Company, the trolley jammed, but nothing worse occurred than a small amount of damage to the trolley and wire, and a temporary block.

New Use for Rontgen Rays.—According to the New York *Electrical World*, Dr. J. C. Perry and Mr. W. C. Cheney, superintendent of the Portland General Electric Company, have been very successful in defining free gold in quartz by means of Röntgen rays. If this is so, it is evident that the definition of "visible gold" will have to be enlarged and the mining prospector will be worried with another new test.

City and Guilds of London Institute.—An exhibition of the work done by students of the technological classes in connection with the City and Guilds of London Institute has been opened at the Imperial Institute. Sir Frederick Abel, in performing the opening ceremony, remarked that the rapid development of the operations of the institute showed that the country was waiting for the the work which the City and Guilds undertook.

The National Swiss Exhibition.—It is stated that the Lord Mayor and Sheriffs of London, in a cordial reply to the President of the Administrative Council of the city of Geneva, have conveyed their pleasure at receiving the invitation to visit the National Swiss Exhibition at Geneva. They, however, fear that it will be impossible for them to visit the exhibition together, though they hope to arrange, while on the Continent during the summer, to attend individually some of the *fêtes*.

Proposed Pacific Cable.—Sir M. Boyle, Mr. Sandford Fleming, and Sir Donald Smith, who have been appointed to represent Canada at the forthcoming conference on the subject of direct cable communication between England and her Australasian colonies *vid* Canada and the Pacific Ocean, have arrived in England, and called at the Colonial Office. The arrangements for the conference are not yet completed, but it is officially stated that the preliminary meeting of the Commissioners will be held shortly.

The Paris Telephone.—M. Boucher, the French Minister of Posts and Telegraphs, having arrived at an understanding on the subject with the British postal authorities, has decided to establish four fresh telephone wires between Paris and London. This step will be effected without cost to the French Exchequer, as the corporation of the Paris stockbrokers has undertaken to advance the sum of about £26,000, the cost of the aerial lines in French territory and half the cost of the cable across the Channel, the corporation to recoup itself out of the receipts.

Magnetic Crane.—An electromagnetic crane has proved itself very convenient at Woolwich Arsenal in lifting and carrying shot and shell, which, owing to their peculiar shape, are somewhat difficult to handle, their removal formerly occupying much time and trouble. The electromagnet is a solid forging, with a concave-curved base so as to fit on to the projectiles. The wire of the coils round the magnet is mechanically protected by heavy brass flanges and stays. The current used varies from three to four amperes at 26 to 30 volts. The switchboard is on the counter-weights at the back of the crane.

Motorcarts in Court.—It is not yet safe to use a motorcart in London. An electric carriage was caught by a policeman going down Parliament-street at half-past three in the afternoon, at the rate of about five miles an hour, and without any person preceding it to give warning of its approach. On the driver being summoned to Bow-street Police Court to explain to Sir John Bridge what he meant by it, the driver's only excuse was that he had done it before in the aggregate to the extent of about four or five thousand miles. He promised never to do so again—at least we suppose not till the Act gets passed—and was promptly fined 40s. and costs.

Telegraphic Interruptions.—The Berne *Journal Télégraphique* of May 25, in its list of interruptions for the previous month, states that communications are restored over the Nicaraguan land lines after having been interrupted since February 26. Under the head of communications not yet re-established, when the list was compiled, come the Ceara-Maranham cable, interrupted from April 28; the San Thomas-Loanda cable, from May 2; and the Amazon Company line beyond Monte Alegre, from May 2; while the Rhodesia troubles are represented by interrupted communication between Gwelo, Fontesvilla, and Beira since April 2. Except the old-standing ones, such as the Brest-St. Pierre cables, the rest were interruptions of only a brief duration.

Institution of Electrical Engineers.—We have the *Journal* of the Institution of Electrical Engineers covering the proceedings up to the end of March last. It may be a small thing, but it is worth noting that there has been a decided improvement in the way in which the *Journal* is put up for sending out, and the edges of the book are no longer cut and damaged by the string used to secure the cover. Of 27 abstracts no less than 11 relate to the subject of the Röntgen radiations. A meeting of members only has been called for four o'clock to-day (Friday), at 28, Victoria-street, S.W., for the discussion of business connected with the Institution. As we apprehend the circular convening the meeting to be a private one sent to members only, we have not felt at liberty to publish the resolutions which will be proposed.

Telegraphs in Africa.—After a break extending over six weeks telegraphic communication is once more established between Blantyre and the south. It appears that in Nyassaland the climate of the Zambesi valley and the difficulties of the country are not the only obstacles which the telegraphic engineer has to surmount, since this particular break in communication was due to a dispute between a Portuguese official, Lieutenant Correia, and the representative of the African Trans-Continental Company,

Digitized by Google

Lieutenant Correia seizing the company's office and instruments at Tete. This action was dissented from by the Portuguese commandant at Tete, and Lieutenant Correia was recalled to Quilimane. Further south, towards Rhodesia, part of the line between Salisbury and Tete is still incomplete, but it is hoped that it will be completed now that the rainy season is over and more labour obtainable. Messages, however, are got through over the gap by a wire laid temporarily along the trees. Still further south there are, of course, the Matabele to be reckoned with.

The Southsea Accident.—The Portsmouth Electric Lighting Committee have received a report from Major Cardew, of the Board of Trade, relative to the recent accident in Middle-street, when a cabman named Foote was injured by an electric shock from a lamp column. Major Cardew reported that he had examined the column and switch and found them in perfect order, the explosion being due to an escape of gas. There was no electric leak, but the gas had escaped from a pipe, which was found to be broken in two, and passed through the ducts to the column. When the arc light was turned out and the incandescents switched on, the gas exploded and caused the accident. As, however, the injured man appeared to show signs of having not merely received a blow from a portion of the lamp column, but also to have sustained injuries such as might have had an electrical origin, the muscles of his right arm being contracted, Major Cardew laid the point before Lord Kelvin, who suggested that as flame was a conductor of electricity, the current might possibly have been communicated to the man in that way.

Motors for Sugar Works.—M. Désiré Korda, of the Compagnie de Fives-Lille, has contributed an article to the *Revue Generale des Sciences* on the employment of three phase current motors in sugar works. The centrifugal separators used in works of this kind go at from 600 to 1,500 revolutions a minute. The mass is considerable, and the axis of revolution vertical. It will be seen at once that a complete balance is important, and that a direct-coupled motor gives a more suitable method of driving than any possible arrangement of belts or gearing. Moreover, there are frequent stoppages, so that three-phase machines which have no commutators to spark are preferable to direct-current motors. An interesting example is the application of three-phase motors to Huebner centrifugals, which require to be capable of being driven at two speeds—say of either 500 or 1,000 revolutions a minute. This might be done either by doubling the number of poles on the motor or doubling the frequency of the alternations. The latter system involves two sets of generators and plant, but it is the one that has been for various reasons adopted at the Abbeville Sugar Works and the Sommier Refinery.

A Street Railway Strike.—The *Western Electrician* (Chicago) gives some details of a strike of about a thousand motormen and conductors in the employ of the Milwaukee Street Railway Company, by which the service of the cars in that city was for the first time in its history stopped The demands of the strikers were for more pay, rearrangement of hours, a recognition of their union, all of which are of the usual character, but the last one is peculiar—namely, permission to order and purchase uniforms for themselves from any tailors they choose. The City Council interposed with a mediation committee, but as it at the same time proceeded to discuss resolutions for revoking the company's "franchise" and acquiring "by purchase or condemnation" the tramway system, its impartiality was naturally somewhat under suspicion, and it is not surprising that its efforts in the direction of conciliation were a complete failure. Meanwhile, the company imported workmen from other cities, and according to the latest reports had succeeded in running about two-thirds of the average number of cars, in spite of the usual obstructions in the way of stones, crowding, and blocked switches.

The Kelvin Jubilee. — The programme of the approaching celebrations of the jubilee of Lord Kelvin as Professor of Natural Philosophy in the University of Glasgow has been given in *Nature*. On the evening of Monday, June 15, at 8.30 p.m., the university will give a conversazione, when there will be an exhibit of Lord Kelvin's inventions. On Tuesday, June 16, addresses will be presented to Lord Kelvin by delegates from home and foreign university bodies, from several of the learned societies of which he is a member, from student delegates from other universities, and from the students and graduates of the University of Glasgow. It is expected that the honorary degree of LL.D. will be conferred on the same day on several of the distinguished foreign visitors. On Tuesday evening, June 16, the city will give a banquet to Lord Kelvin, to which the visitors who have come to do him honour have been invited. On Wednesday, June 17, the senate of the university will invite the visitors of the university staff to sail down the Clyde. The students of the university also invite the student delegates from other universities to a similar trip. Representative scientific men—about 50 in number—from America and the British Colonies, and from all the European countries, and about 150 from the United Kingdom have signified their intention to be present.

Telephoning the Paris Opera.—On the evening of the 21st inst., with the co-operation of the British and French postal officials, the experiment was tried of bringing the music of Mr. Duvernoy's new opera, "Hellé," then being performed at the Grand Opéra, Paris, over the telephone, so that it could be heard through the electrophone at Pelican House, London. The co-operation of the weather, however, could not also be secured, and a storm, worse in France than in England, played havoc with carefully-prepared arrangements, so that perfect communication could be established no further than Calais. The visitors invited had therefore to be satisfied with selections from the London theatres. A second attempt was made last Friday, and this time it succeeded. The sound, it is true, was rather faint, but the voices came out with delightful clearness, particularly that of M. Delmas and the tenor, M. Alvarez, who was singing for the last time in Paris prior to his visit to Covent Garden. The female voices were not quite so distinct, nor were the violins of the orchestra very audible, but the brass instruments made themselves evident, as is their custom, while a phrase for oboe came over the wires with great clearness. Only about a dozen scientific and musical people were present. After a certain amount of "Hellé," the electrophone was put on to comic opera, but, apparently resenting the degradation, did not seem to perform so well.

An Arabian Thunderstorm.—It is currently believed that it never rains at Aden, though more careful and accurate residents there say "only once in five years." But it appears that the climate is changing. In view of the water-tanks built by the Government, that is kind of the climate. The telephone and telegraph people there, however, do not like the change. At the end of last month there was a regular thunderstorm, and it seems to have proved altogether too much for them. "It was so dark that the electric light had to be used in the office of the Eastern Telegraph Company. The cables were much affected, and the work somewhat delayed. The telephones, too, were disturbed, and the captain of the Aden troop, wishing to speak to the general's aide-de-camp

Digitized by Google

at the Residency, suddenly received a shock. The A.D.C., who was listening, said he, too, felt as if he had a violent blow in the chest, and declined to go near the instrument for some time. The manager of the new bank suffered still more; he was holding the receiver to his ear, and received such a shock that he could not use his hand for over an hour. In the E.T.C. superintendent's bungalow a flash of lightning seemed to light up all the wires, and rang the telephone bell." As it is hardly probable that an Arabian thunderstorm would specially select telephones as the subject of its attentions, these little difficulties will doubtless be got over in time at Aden, as they have been elsewhere.

High-Voltage Lamps.—In its issues of May 14 and May 21 the *Elektrotechnischer Anzeiger* devotes two articles to Mr. G. L. Addenbrooke's paper on "High-Voltage Lamps" at the Institution of Electrical Engineers and the discussion which followed. Our contemporary does not seem altogether satisfied on the question of the advisability of adopting a 200-volt system. At any rate, after emphasising the necessity on double-voltage systems of installing arc lamps in groups of not less than four or five lamps each, even though only two may be required, or, in the alternative of putting in a smaller number, having to pay just the same for the energy wasted in resistances, the second article, which is signed by Mr. F. Grünwald, comes to the point with a comparison of the cost of using high-voltage lamps or high-efficiency lamps at 110 volts. By assuming an efficiency of four watts per candle for the high-voltage lamp and 2½ watts for the 110-volt one, and making the amount of copper conductor per lamp small enough, there is no great difficulty in showing an advantage in using the lower voltage. But, unfortunately, the 2½-watt lamp is a thing that is much more talked about than seen. However, in spite of its comparison of cost, our contemporary's conclusion is not to condemn the double voltage altogether, but only that "the four-watt lamp for 220 volts is a makeshift," and that the aim of the lamp manufacturers should be to produce a better efficiency and longer life.

Electric Turret Gear.—In its "Naval Intelligence," the *Times* has remarked on the number of foreign warships which are now fitted with both electric and hand gear for the movement of turrets and guns and the working of ammunition hoists. The latest addition to the number of these is the "Emperador Carlos V." armoured cruiser, launched in 1895, and now being pushed forward to completion at Cadiz. This vessel carries two 11in. Hontoria guns, forged and built at Creusot, in revolving turrets, one fore and the other aft, as her principal armament. The vertical movement of the guns is effected by means of a hand-winch, but the Forges et Chantiers de la Méditerranée are supplying electric gear for the working of the hoists and the revolution of the turrets. The electric apparatus is beneath the armoured deck, and is operated by a switch from the turret; but, in case of failure, both the hoist and the turret can be worked by hand. A like arrangement has been fitted by the same company in the Danish armoured gunvessel "Skjold," which is in progress at Copenhagen. The "Capitan Prat," built for the Chilian Government at La Seyne, was the first warship to attract attention by the application of electricity to the movement of her guns, and it will be remembered that a description of the apparatus appeared in this journal some time back. Subsequently, in the French service, the system has been applied in the "Jauréguiberry" and "Saint Louis" battleships; the "Latouche-Tréville" and "Pothuau" armoured cruisers; and similar gear is fitted in the "D'Entrecasteaux," first-class cruiser, now under construction at La Seyne.

Metric Screw Threads.—Attention has been called in *Cassier's Magazine* to the fact that up to the present the metric system has failed to meet the requirements of machine-shop practice in so far as concerns the providing of a convenient system of screw threads. Numerous attempts to devise metrical screw-thread systems have been made, but no one of these has thus far met with sufficient approval to secure general adoption. It is very much easier to adopt a new system than it is to throw away an old one, and hence each attempt to improve the metrical screw-thread systems has simply resulted in the addition of one more to the existing list without superseding any of the preceding ones. Thus there are in France the systems of the French navy, of the Chemin de Fer du Nord, of the Paris-Lyons Mediterranée Railroad, and those of Armengaud and of Cail. In Switzerland there are the systems of Reishauer and Bluntschli, and of Bodmer; in Germany, the two systems of Ducommun, that of the Engineering Society of Mulhausen, the system of the Pfalz-Saarbruck Society, that of Redtenbacher, and the two systems of Delisle, the latter one of which has also been adopted by the Society of German Engineers. There are thus no fewer than 14 different metrical screw-thread systems, no two of which will interchange. The difficulty appears to consist in the fact that the decimal subdivisions or multiples of the millimetre do not give sizes which conform to the mechanical requirements of strength, wearing capacity, and convenience of angle, while the introduction of other than decimal fractions is supposed at once to take any system out of the pale of metric orthodoxy.

The Jacques Cell.—Some time ago we gave an account of the carbon-consuming primary battery invented by Dr. W. W. Jacques, of Boston, in which it will be remembered the carbon is immersed in caustic soda maintained at a temperature of 800deg. F., or over, and traversed by a continuous supply of air bubbles, the whole being contained in an iron pot, which forms the other terminal, and which is surrounded by a closed furnace to maintain the temperature. At the time no figures at all were available as to the performance claimed for this somewhat eccentric-looking arrangement. It appears, however, that Dr. Jacques has had a 100-cell battery of this type in operation for experimental purposes for the last six months or so, the cells of which consist of iron pots 12in. deep and 1½in. in diameter. What is claimed for the battery had better be given as printed by our contemporary and namesake, the New York *Electrical Engineer*—namely, that "In a recent test made by Messrs. Stone and Webster, of Boston, the apparatus maintained 30 16-c.p. lamps at full brilliancy. It was found that to maintain these lights for 18¾ hours required the consumption in the pots by oxidation of about 8lb. of carbon. The average pressure during the test from the 100 cells was 90 volts and the current 16 amperes. Messrs. Stone and Webster report that the electrical energy actually obtained from the carbon consumed in the pots was 82 per cent. of the theoretical." These figures are curious enough without any statement of the amount of coal burned in the furnace to keep the soda hot, or, which is altogether a minor matter, the proportion of the current generated which is required to work the electrical pump used to drive the air through the electrolyte.

Electric Light from the Waterworks.—It has been pointed out many times that power for a small installation may advantageously be obtained from the natural enemy of electric lighting—the gas company—by means of a gas-engine. In France, however, they have gone so far as to propose to fall back on the waterworks when the power required is very small. At any rate, a

Digitized by Google

correspondent has written to *L'Etincelle Electrique* to enquire why the water supplied under pressure by a town waterworks cannot be used to generate electric current by means of a turbine and dynamo. It may be noted, in passing, that the tiny turbine actuated by the town water supply has long been a foible of our neighbours across the Channel. The answer of our contemporary is, of course, that if you cannot get current from any other source, even a primary battery would in most cases be cheaper. The cost of current from a battery is put at from 2s. 5d. to 5s. 9d. per unit—we should much like to see the authority for the lower price. In France water is supplied at so much per cubic metre, and in the metric system the price and pressure—*i.e.*, "head"—required to compete with these prices would be easily calculated were it not for the fact that the efficiency of the turbine and dynamo come in. These being small, their efficiency is put at 60 per cent. and 70 per cent. respectively—*i.e.*, a total of 42 per cent. Of course quite a table of results may be brought out by varying the assumed prices and pressure, but the general conclusion attained is that with water at five centimes (less than ½d.) per cubic metre, which is the lowest price assumed, the water power would come into competition with the battery as soon as a pressure of a 10 metre or 32½ft. head is available. It is obvious that as the price increases so does the pressure required. In conclusion, Mr. E. Rivaud, who is responsible for the article in *L'Etincelle*, considers that there are cases where the small turbine and dynamo would be preferable to a battery, as where the price is approximately the same such an arrangement would be more convenient in use.

The Bedford Accident.—The inquest on the death of Albert Edward Christmas, who was also known by the name of Bates, has taken place, and terminated in a verdict of accidental death. It appeared that the deceased was working, with another man named Tacchi, at the St. Mary's transformer sub-station of the Bedford Corporation electric lighting system, both men being under the direction of a foreman named English. The last-named took the fuses, which were made of copper wire, out of the fuse-box in order to make the transformer "dead." Indiarubber gloves were provided, but on this particular occasion he did not use them. English told Tacchi and deceased to lift the fuse-box off the transformer cover. They proceeded to do so, and English, after having taken out the fuses, held the high-tension mains clear for them so as to allow them to get the box down. Deceased and his fellow-workman Tacchi commenced to lower the box, and had got it down about 8in., when the two men received a shock, Tacchi falling down on one side and deceased on the other. Tacchi fainted, and in a short time, about a minute or less, recovered, but deceased remained on the ground, lying on his back. English believes that he was not at that time dead, though he did not live more than three minutes. On examination there was found to be a small hole in the insulation of the high-tension cable. On this point evidence was given by Mr. Hope-Johnstone, the engineer of the Corporation electric lighting works. It was his opinion that the accident had been caused by the flaw in the insulation of the high-tension cable. The insulation was torn, looking as if it had fallen on something. He believed that the flaw was not there when the cable was first laid down. All cables were tested under water, after 24 hours' immersion at the manufacturer's works. They were tested again after the cable was laid down, before being brought into use. It is curious to note that, so far as can be seen, the circumstances under which Christmas and Tacchi received the shock were as nearly as possible the same—in the one case the result was immediate death, while in the other there was little or no permanent injury. It should be added that artificial respiration was tried in the case of Christmas under favourable circumstances, a medical man being on the spot almost immediately, but, as will be seen, it was without effect.

University of London.—We noticed last week three letters which appeared in the *Times* from Drs. Collins and Napier and Sir George Young on the subject of the reorganisation of the University of London. These letters have naturally called forth a reply from Dr. Silvanus Thompson, which takes up the best part of a *Times* column. "Dr. Collins and Dr. Napier," he says, "once more trot out their statistics of that notorious business of the circulars by which, under pretence that they were making the enquiry on behalf of the Lord President of the Council, they deluded some 1,800 of the graduates into signing certain postcard replies to questions so ingeniously framed that any reply, whether affirmative or negative, would commit the answerer to a position of hostility to the scheme of reconstruction as proposed by the Cowper Commission. As to the morality of sending out those circulars in envelopes marked like official documents of Convocation, the less said the better. They have had their reward—a paper triumph which on analysis is destitute of weight. Though we know the extraordinary efforts and the specious arguments used to extract this vote, to this day we do not know who the 1,800 graduates are, nor what means they possess of coming to a sound judgment on the real issues involved. On the other hand, we know that by increasing majorities, and by a decisive majority of the graduates best able to enter into the issues, Convocation has, in the only legal way open to it under the charter, pronounced in favour of a reconstruction in general conformity with the scheme of the Cowper Commission." On the subject of different examinations for resident and non-resident students, Dr. Thompson points out that a hard-and-fast rule is impossible. "Anyone acquainted from inside with the working of the higher education must recognise that what may be quite right in one faculty may not be good in another. In a subject like mathematics there may be no valid reason for giving to a non-collegiate student any different examination from that given to a collegiate student. But there are subjects in which this is not so. Consider the case of subjects like physics and chemistry, in which the collegiate training is mainly carried on in elaborately-equipped laboratories, and necessarily differs from any training which a private student can possible acquire on his own resources. The educational interests of both classes of students here demand separate examinations; for the external students would be at a serious disadvantage in entering an examination based on the training of the laboratory, and the internal students would be very unfairly treated if compelled to work for an examination that ignored the laboratory training." Dr. Thompson urges that the decision on such a point as this must be left to the senate to deal with *pro re nata*, and concludes by asking whether as the whole of the bodies concerned have now expressed their general agreement in the scheme of reconstitution, it is not time that Parliament should intervene, and, while giving the extremists of both sides every opportunity of being heard in the final adjustment, without delay appoint a tribunal to hear them, and carry out the long-delayed scheme.

The Telephone Company.—Two letters relating to the National Telephone Company which have appeared in the *Times* during the past week are not without interest in their way. The first is from Mr. George Barham, of Harrow, who wants "to caution landowners and occupiers against the vandalism of the National Telephone Company

Digitized by Google

and their employés, which unless put a stop to will ruin the beauty of some of the prettiest roads in the kingdom." "On Saturday morning," says Mr. Barham, "on coming out of my house I observed six men, with three ladders, hacking and sawing branches, 10ft. and 12ft. long, and 4in. to 5in. in diameter, off well-grown trees which border the main road from London to Harrow. On being spoken to they refused to desist, saying they intended to carry out the orders of their foreman, who had obtained the permission of the 'gentleman.'" As Mr. Barham happened to be the "gentleman" — *i.e.*, the owner and occupier of the property—this tale did not work. Further damage was stopped, but "the branches cannot be restored, and two elm trees, an ash, and a well-grown chestnut have been irretrievably spoilt by the National Telephone Company. The loss is not mine only, for these very trees have been chosen by the artist to illustrate 'Picturesque Middlesex,' and are situate in the prettiest part of the Harrow-road. The Post Office authorities recently put a telegraph line along the same road, and sooner than injure the trees they asked permission to place a pole on the land at the back, to which I readily gave consent." Of course they did, for the Post Office knows well enough that even a Government monopoly does not carry the right of unlimited trespass, and when you want to make use of other people's property for your own convenience, the proper way—and in the end the best—is to ask permission in a civil manner. The second letter is from Mr. Faithfull Begg, M.P., who apparently having only just heard of Mr. Henniker Heaton's letter of April 23, wants to answer it. The answer is to the effect that Mr. Henniker Heaton does not know what he is talking about. "His references to the recent agreement between the Department and the National Telephone Company show that he is apparently ignorant both of its genesis and contents. The Department, having granted a license, desired to modify its terms. Hence they were under the necessity of negotiating, and have made the best bargain they could. The right to purchase in 1911 is not founded upon the new contract, but upon the original license." Mr. Begg makes one point neatly enough from a dialectical point of view. Mr. Henniker Heaton's description, he says, "of the Post Office as capable of giving a cheap and perfect system, sounds strange in the mouth of one whose life work appears to be to prove that of all the incompetent departments that ever existed the Post Office is the worst." But perhaps Mr. Henniker Heaton thinks that he and his friends in Parliament can do something to keep the Post Office in the way it should go, while they are quite powerless to put pressure on a private company. If so, that would be a good enough answer. In the last sentence, however, of his letter Mr. Begg ends by coming to at least a nominal agreement with his adversary. "My own opinion is that the Government should purchase, and should purchase now. Probably in that Mr. Henniker Heaton and I are in agreement." If the conclusion is the same in each case, why dispute as to the different ways in which it has been arrived at?

Magnetism at Low Temperatures. — Some interesting investigations on the effect of extremely low temperatures on the magnetic properties of iron and steel have been embodied in a paper by Profs. Dewar and Fleming which has been read at the Royal Society. Knitting-needle steel at various tempers, chromium, aluminium, and nickel steels, pure nickel, silicon steel, and soft and hard iron were experimented with, the samples tried being made up in the form of small needles about 15mm. (·6in.) long and magnetised to saturation. They were brought to temperatures as low as −185deg. C. by means of liquid air and tested in a reflecting magnetometer. Broadly speaking, the results obtained were: 1. That the sudden cooling to the temperature of liquid air usually permanently decreases the magnetic moment of short magnets made of many varieties of steel, assuming them to have been initially magnetised in a strong field. 2. This initial decrease is found both in hardened steels having great coercive force, and also in the same steels in a soft or annealed condition, and is especially conspicuous in the case of the 19 per cent. nickel steel. 3. In the case of most steels the effect of cooling magnets made of them to −185deg. C. is to temporarily increase the magnetic moment after the permanent magnetic condition has been reached. 4. The exceptions to the above rule are the nickel steel with percentages of nickel from 19 to 29 per cent., in which case the magnetic moment is always decreased temporarily by cooling to −185deg. C., after the permanent magnetic condition has been reached. 5. It appears that one of the best ways of ageing a permanent magnet is to dip it several times into liquid air. It then arrives at a constant condition in which subsequent temperature changes have a definite effect, and in which the sub-permanent magnetism is removed. In order to determine if similar changes of magnetic moment could be produced in the case of soft annealed iron, small magnets of Swedish iron were prepared, formed of a short length, about 15mm., of soft iron, or a small slip of annealed transformer iron. On magnetising these in a strong field, and testing them with the magnetometer, and cooling them by immersing in liquid air, it was found that the first effect of the cooling was to produce a small diminution in the magnetic moment, and the subsequent heating in some cases produced a further diminution of magnetic moment. In the first sample of soft iron, the wire was about 3cm. long, and bent into a U shape, with ends about 10mm. apart, and in this case the changes of magnetic moment were similar to those in the case of the carbon steels, only with very much narrower limits of variation. The first cooling hardly produced any change whatever in the magnetic moment of the magnet. On allowing it to heat up again, the magnetic moment was very slightly diminished, and thenceforth the changes of moment were such that the magnetic moment was greater when the magnet was cold than when it was warm, by about 2 or 3 per cent. of the latter value. In the case of a straight soft-iron magnet formed of annealed transformer iron, the curious fact was noticed that whereas a rapid cooling of the magnet by plunging into liquid air hardly produced any effect on the magnetic moment after the first initial loss of magnetism had taken place on cooling, the effect of a slow cooling down to the temperature of −185deg. C. was always to produce a permanent diminution of magnetic moment. Hence the magnetism of this soft-iron sample could be frittered away by a process of slow cooling to −185deg. C., and intermediate heating up to 50deg. C. A sample of the same iron, hardened by hammering, was tested, and was found to behave in a very similar manner to the glass-hard carbon steel, the changes in magnetic moment being relatively about the same percentage for the same temperature change—that is to say, the magnet had a moment of about 10 per cent. greater at −185deg. C. than at 5deg. C. Since a 19 per cent. nickel steel magnet increased in magnetic moment when heated from −185deg. C. to +5deg. C., and since it is well known that at some higher temperature it would lose its magnetism altogether, it follows that there must be a temperature at which it would have its maximum magnetic moment. After repeated heatings and coolings this temperature was found to be about 56deg. C.

CABLE-LAYING ON THE AMAZON RIVER.*

BY ALEXANDER SIEMENS, M.I.C.E., M.I.E.E.

When it had been decided to connect Belem, the capital of the State of Pará, by means of a subfluvial cable with Manaos, the capital of the State of Amazonas, a preliminary journey became necessary, during which landing places at the various intermediate stations had to be selected. As no reliable charts exist, some reaches of the river had to be explored, and various other details ascertained in order to facilicate the laying of the cable. This preliminary survey took place in October of last year during the hottest season, when the river was at its lowest, while the cable was laid during January and February of this year, when the rainy season had commenced and the river was rising. The difference in temperature between the two journeys was on the average not more than about 5½deg. C. (10deg. F.), but a great advantage during the laying was the almost continuous presence of clouds, which mitigated the fierce heat of the sun and kept the temperature at a very pleasant level. The diagram (Fig. 1) shows the curves of the variation in temperature during the cable-laying expedition, and gives the daily maximum and minimum temperature registered by a thermometer hung up under the officers' bridge in the open air, but sheltered from the sun. The third curve represents the temperature of the water, which was measured by a thermometer on the refrigerating machine fixed at a point where the water pumped in from outside first enters the machine. Besides the date, the places where the observations were taken are marked on the diagram, and it will at once be noticed how very equable the temperature was on the main river. The fluctuations in the air temperature are mostly indicating the absence or presence of clouds, but the water temperature remained perfectly constant during the whole time that the ship spent on the upper reaches of the river. The proximity of the sea lowers the temperature only to a small extent, as is clearly shown by these curves. A glance at the map of South America explains without much comment how immense the volume of water must be which is collected from an area measuring more than 2½ million square miles, for the most part covered with dense forests; and it follows that the temperature of such a body of water cannot be seriously affected by the daily variations of temperature indicated by the first two curves. It is extremely difficult to realise the true proportions of this river, but the comparative table, in which the dimensions of the principal rivers of the various continents are contrasted with those of the Amazon, will help to show the importance of this great system of natural waterways. With several other large rivers, the Amazon shares the fate that its name changes several times during its long course, and that at various times different affluents have been considered to be the true source of the main stream. Most geographers, however, regard the Marañon as the principal river, a branch of which, called Tunguragua, rises in Lake Lauricocha, in Peru, in 10deg. 30min. S. lat. and 76deg. 10min. W. long.; although the Ucayale, where it unites with the Marañon at Nauta (4deg. S. lat., 73deg. W. long.), is quite as important as the Marañon. If the greatest distance from the mouth is to decide the question, then the source of the Apurimac, an affluent of the Ucayale, can lay claim to being the origin of the Amazon, rising in Peru in 16deg. S. lat. and 72deg. W. long. From the Lake Lauricocha the main direction of the Tunguragua and the Marañon is to the N.N.W. until the river turns eastward, and shortly after passing Jaen breaks through the Andes, entering the plains of the Amazon valley by the Falls of Manseriche a short distance west of Borja. Its further course is a little north of east until it pours its yellow waters into the Atlantic under the equator between the Cabo do Norte and

TABLE SHOWING DIMENSIONS OF PRINCIPAL RIVERS.

Name.	Length, in statute miles.	Watershed. Square miles.	Average discharge, cubic feet per second.	Length of navigable waters, in miles.
Mississippi (1)	2,616	1,285,300 (6)	675,000	35,000

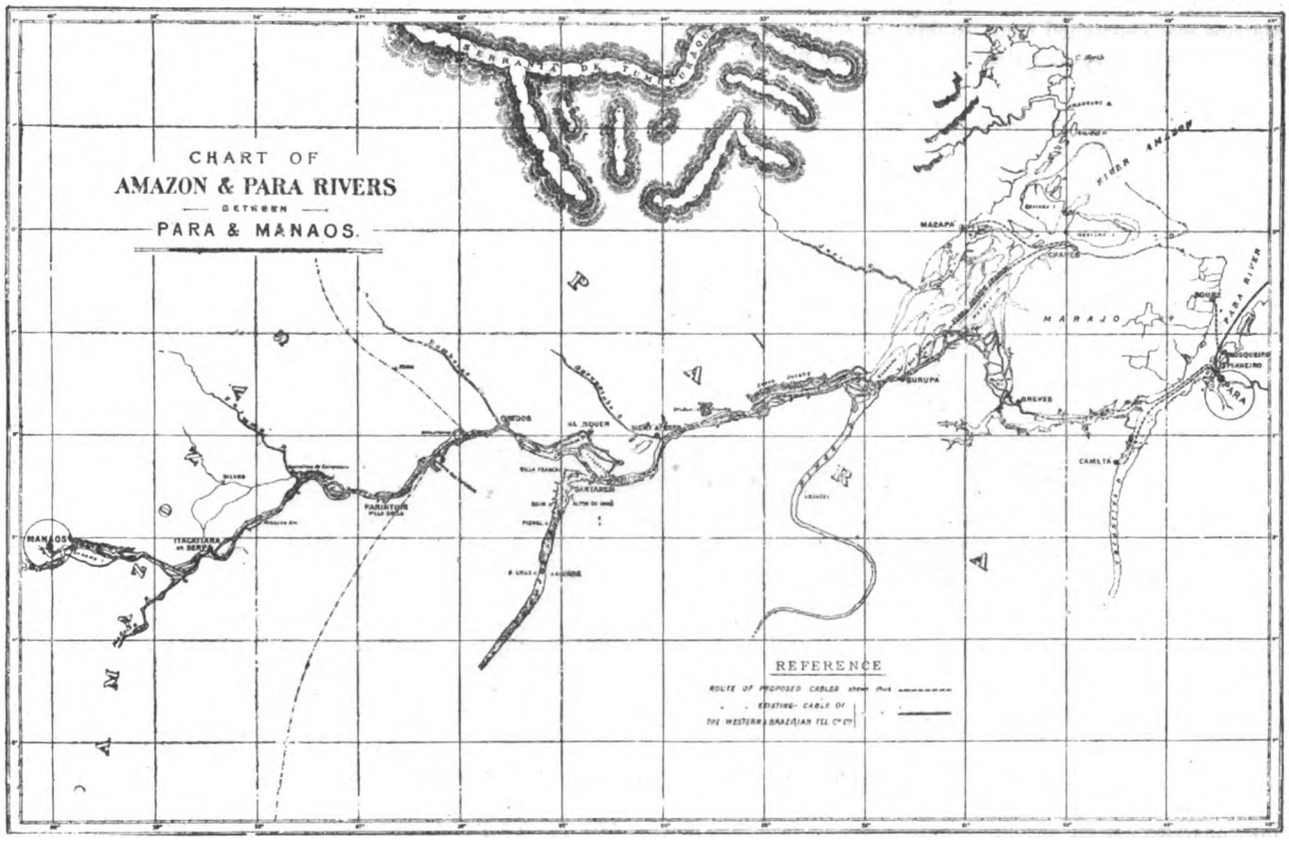
the Cabo Maguari, which are 158 miles apart. This distance is just about equal to the distance from Lands End to Cape Clear in Ireland, or from Brighton to Falmouth. Even west of the island of Caviana, which lies in the mouth of the river, together with the island of Mexiana and several smaller ones, the width of the main stream is over 50 miles, equal to the distance from Portland Bill to the Cap de la Hague. The part of the Amazon flowing north of the island of Marajó may therefore be compared in width to the Channel, but in depth and volume of water it far surpasses it. It is a disputed question whether the water flowing south of Marajó, commonly called the Pará River, should be considered as part of the Amazon or not. A network of natural canals, "the narrows," connects the two waterways west of Marajó, but the influence of the tide makes it difficult to decide whether part of the water of the Amazon finds its way south of Marajó or not. Along the whole course of the Amazon, commencing at the foot of the Andes, a similar network of islands and canals is formed on both sides of the river, as the whole country is almost level, and is consequently inundated during the rainy season for hundreds of miles by the rivers flowing



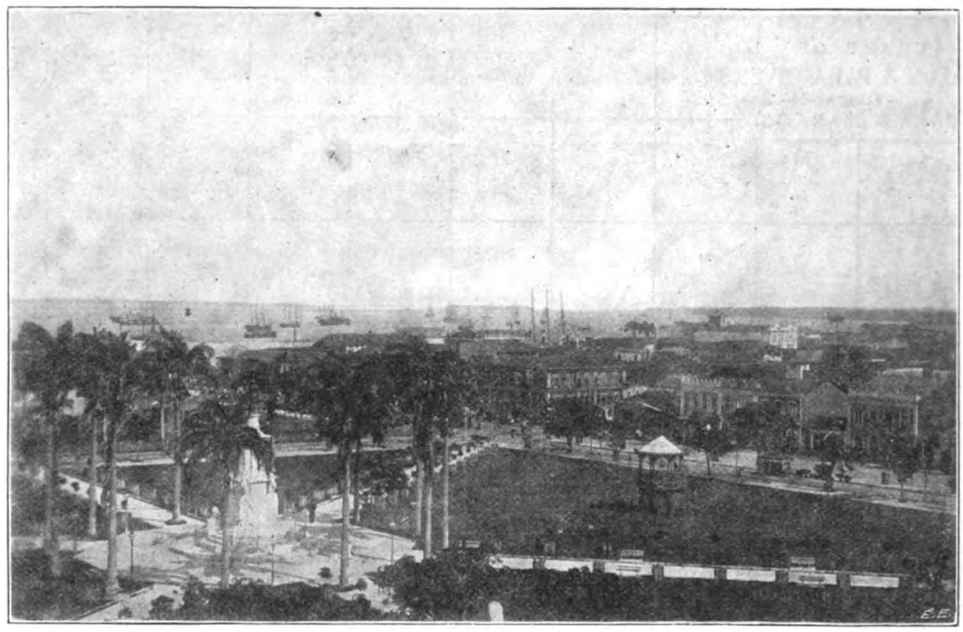
through it. The most notable exception to this general state of things occurs at Obidos, where the whole volume of water is compressed into one channel a little over a mile wide, and said to be about 40 fathoms in average depth. A sounding taken opposite Obidos, about a third of the distance across the river, showed a depth of 58 fathoms, measured by a steel wire and Sir William Thomson's sounding machine. As the current of the river averages three knots in the main channel, it is not easy to take soundings by an ordinary lead-line, and even with the steel wire an extra heavy weight (33lb.) has to be employed, or the results are not reliable. Besides the wire sounding machine, a submarine sentinel was used on the preliminary voyage wherever serious doubts existed about a channel through which the cable was to be laid. This apparatus consists of a small winch, from which a wire leads into the water and drags at a short distance behind a piece of wood, shaped like an angle iron, in a nearly upright position. The wire is not attached directly to the piece of wood, but to a string, kite fashion, and the wood is fitted with an iron foot, which, on coming in contact with the bottom of the water, releases one end of the kite string, so that the wood remains attached to the winch wire with one end only. The consequence is that the strain on the wire is suddenly reduced to a very small amount, and the piece of wood appears on the surface of the river. It depends on the quantity of wire paid out how deep the kite or the sentinel floats, and its action is quite reliable, so that it is unnecessary to take soundings by the line or by wire while the sentinel is being dragged by the ship. Usually the sentinel was set at five fathoms, and when it struck a bar the ship was stopped, and a series of soundings taken to ascertain the exact depth of water and the extent of the shallow place. A further difficulty in sounding originated from the soft nature of the soil, which, for the greater part of the Amazon valley, is alluvial clay, and allows the lead to sink into it for several feet. In the narrows there appears, however, a bank of hard clay, called *tabatinga*, which unfortunately blocks nearly all the branches of the narrows and creates bars all along the course of the Tajipuru, the main westerly waterway connecting to the Gurupá branch of the main river. Occasionally the same hard clay forms shallows in the main river, but as a rule the section of all the channels resembles the capital letter U—*i.e.*, the sides are very steep and the bottom flat. In this respect, as in many others, the Amazon differs entirely from the Indian rivers, which build up their beds above the surrounding country, occasionally breaking through their natural banks and seeking a new bed. The Amazon, on the other hand, carries with it only the light clay sediment which forms the soil of the whole valley, and the inducement for the main stream to alter its course is therefore very small, and long straight reaches are the result. Under these circumstances the largest vessels can ascend the river nearly to the foot of the Andes, but the constantly changing sandbanks at the mouth of the Amazon proper make this approach of the river dangerous, and the State of Pará is, for obvious reasons, not over-anxious to have the deep channels properly buoyed and surveyed. This forces all the shipping to enter the Pará River and to pass the narrows if the Amazon is the goal of the journey. In doing the latter, the choice for large ships lies between one of the channels (called *furos*) with a bar where it joins the Tajipuru and a *furo*, the Macajubim, which has plenty of water, but which winds about in such a serpentine fashion that only ships with twin screws can pass it unassisted. These difficulties are, however, much diminished during the rainy season, when the river rises to such an extent as to drive all the inhabitants of its banks into the towns which have been built wherever a natural eminence secured the inhabitants against the flood. Near the mouth the differ-

Digitized by Google

ence is naturally not so great as higher up, where the influence of the tide is felt less, but at Manaos the difference in level between low river and high river exceeds 40ft.

With all rivers carrying sediment, the Amazon shares the peculiarity that its immediate banks are higher than the country lying behind them, and thus we have in the rainy season the spectacle of the main river flowing between two banks covered with dense forest and immense lakes stretching out on either side of these banks. These do not entirely dry up during the remainder of the year, so that the whole of the Amazon valley really forms a huge swamp covered with a most luxuriant forest, which below Manaos narrows to a broad belt close to the main river with prairies, called *campos*, at the back of the forest stretching out to the hills, where the forest recommences. In such a country no land communication of any sort can be attempted, as the tropical vegetation and the annual inundations of the rivers destroy everything that man places in the way of the natural forces. By water, on the other hand, the intercourse between all habitable parts of the country is easy and expeditious since steamers have been introduced in the year 1853. At that time the journey from Belem to Manaos was shortened from 40 days to eight days, and at present the ocean-going steamers, which do not call at the intermediate places, accomplish the distance in three days. Belem, the capital of the State of Pará, lies on a branch of the Pará River, called Guajará, which unfortunately does not share the characteristic shape of the Amazon and the *furos*, but forms a rather shallow basin in front of the town. The general aspect of the town, but for the presence of palm trees, does not differ much from that of a European seaport. Even the clothing of a good many inhabitants seems better adapted to a colder climate; it is only the airy costume of the ladies, and still more the absence of any costume on the children, that betrays the tropical climate. The harbour of Pará is very full of shipping, and the general build of the steamers is well adapted to navigate the broad waterway of the main river as well as the smaller and shallower affluents, which become more and more inhabited from year to year. As the cable steamer could not approach close enough to Pará, the shore ends were laid with the help of a barge and a tug without anything occurring that need be mentioned. By the same means the sections from Pará to Pinheiro, and from there to Mosqueiro, were laid, the large steamer laying the section to Souré across the Pará River. These three places are much resorted to by the inhabitants of Pará for their healthy situation, and because they imagine that salt water reaches at least Souré. The views show how the forest encircles all the houses, but the proximity of the sea and the breeze blowing regularly every afternoon make all these places extremely comfortable. At Souré the ss. "Faraday" was anchored at a convenient distance from the shore, so that the shore end might be landed direct from the ship, and as long as the tide was rising this plan appeared excellent. By the receding tide, however, a whirlpool was formed with the ship lying right across the centre, and when it had been turned 17 times in one hour the captain was tired of it and moved the ship to a safer anchorage. Another branch of the cable was laid from Pará to Cametá, on the River Tocantins, which is 1,200 miles long, but unfortunately has some rapids not far from Cametá, which cut off the navigable upper portion of the river from direct communication with the general Amazon system. Cametá boasts of a fine old church and a number of two-storeyed buildings, indicating the prosperous state of the township.

The first station on the main cable is Breves, the centre of the rubber trade of the islands of the lower Amazon, situate in the centre of "the narrows." Between Pará and Breves there is only one shallow passage, near the light-house of Gujabal, and the pilot managed to run the ship aground there. Luckily it was low tide, and with the rising tide the ship could be turned. At Breves the ship was anchored close to the shore, and its stern secured to a tree by a rope so that the tide could not cause it to swing. Under these circumstances the landing of the shore ends was an easy matter and soon finished. The ship then resumed its way into the narrow *furos* described above, and the night did not put a stop to its progress, as the outlines of the forest were clearly visible against the sky and the water everywhere more than seven fathoms deep. While the speed of the ship was kept at about six knots, the pilot ordered the quartermaster to put the helm astarboard, as he wished to increase the distance between ship and shore. The quartermaster was, however, confused, and put the helm hard-a-port, with the result that the bows went into the forest until the branches of the trees touched the foreyard. To appreciate the situation, it should be mentioned that the foremast stands 74ft. abaft the bows, and that the foreyard is 69ft. above the water level. Luckily, the soft ground, the elasticity of the forest trees, and the steepness of the banks rendered this accident quite harmless, and on reversing the engines the ship at once came off, so that the laying could be resumed. Not far from this spot the Aturia *furo* branches off, through which the cable had to be laid, but which was impassable for the ss. "Faraday" on account of a two-fathom bar at the Tajipuru end of the *furo*. As a splice had to be made with some cable on a barge from which it was to be paid out through the Aturia *furo*, the "Faraday" had to be

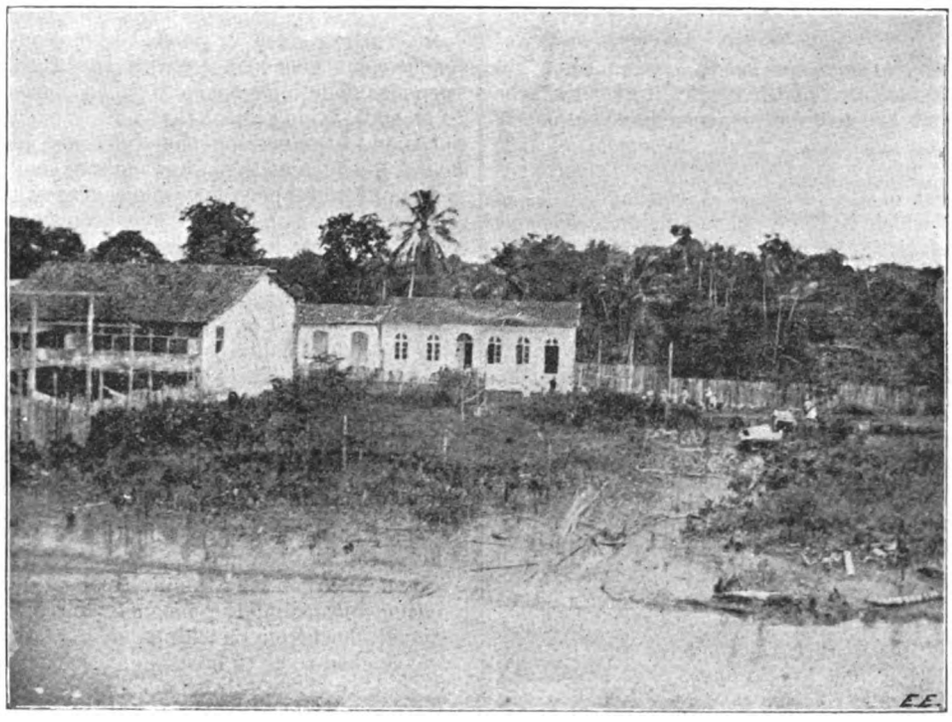


The Harbour at Para, taken from the roof of the Governor's Palace.

Digitized by Google

anchored, and the right-hand shore was approached so as to leave room for the ship to swing round when the tide turned. At the critical moment when the anchor was to be lowered, somebody blundered, and turned the electric light out, leaving the anchor winch and its surroundings in darkness. By the time this mistake had been rectified the ship was dangerously near the shore, and even the anchor could not sufficiently check its advance, so that it ran again ashore, stopping within about 5ft. of a house, much to the alarm of the inhabitants. This manœuvre fixed the ship in a most convenient position, so that it was left there until the splice had been finished and the tug "Cochrane," with the barge, had started laying the cable in the Aturia *furo*. Again there was no difficulty in backing the ship off the bank, but the *furo* proved to be too narrow to turn the ship, which had to return to Breves, or rather a few miles beyond to the mouth of the Boiuassu, in order to enter the *furo grande* and the Tajipuru in a roundabout way. As the ship was drawing over 24ft., and the bar at the end of the Boiuassu had only 23ft. of water at high tide, the result was easily foreseen, but the ship remained on the bar for nine days, by which time sufficient cable had been transferred to the barge and to the ss. "Malvern" to enable the ship to continue her journey. During this enforced sojourn in the midst of the most wonderful combination of islands and rivers, the two naturalists which the British Museum authorities had kindly sent with the expedition took full advantage of the opportunity to explore the locality in all directions.

Unfortunately, the time is too short to give many details of the intermediate stations, but their general aspect is very similar, and nothing noteworthy occurred at most of them. Commencing at the mouth of the river, the first station is Chaves, and the second Macapá; to these two places a branch is laid from Gurupá. The ss. "Faraday" had the distinction of being the first European steamer which has navigated the Amazon river below the mouth of the Tajipuru; in fact, neither the pilots nor the inhabitants knew of any foreign ship that had ever touched at these ports. In Gurupá, the second station of the main line, the inhabitants expressed their joy at being put in communication with the rest of the world by actively helping in the landing of the first shore end. A young lady in white, niece of the Mayor, borrowed a handkerchief from one of our engineers, daintily laid hold of the end of the cable, and triumphantly carried it into the station. Here a ball was started, and the happy couples waltzed round the cable-end to show their appreciation. Meantime, the tug began pulling on the barge from which the cable was to be paid out, and just as these vessels began to feel the current, which runs rather strong there, something jambed, the cable would not run out, and the tug could not hold the barge against the current. Barge, tug, and cable drifted down stream, the end gradually disappearing out of the station. This *contretemps* luckily did not disturb the dancers, who continued their rejoicings until the end had been brought back. Monte Alegre lies on a *furo* which, unfortunately, has a shallow bar at its mouth, so that the cable had to be laid in and out by the barge and tug. This *furo* is swarmed with "botos," a species of dolphin much coveted by the naturalists, but the natives do not try to catch them because they are neither good for food nor useful in other ways; besides they are remarkably shy and strong. From there the cable is laid to Santarem, at the mouth of the Tapajos, which presents a strong contrast to the Amazon on account of its clear waters and tranquil flow. This river is 1,200 miles long, and is formed by the union of the Arinos and Juruena, rising 14deg. 42min. S. lat. and 60deg. 43min. W. long., in the so-called *aguas vertentes* (the turning waters) close to the sources of some of the affluents of the Paraguay River. In the rainy season all these waters mix, and it is possible to pass in a boat from the mouth of the Rio de la Plata in 35deg. S. lat. to the mouth of the Orinoco in 10deg. N. lat. by way of the Paraguay, the Tapajos, the Amazon, the Rio Negro, and the Cassequiare, which forms a connecting link between the Amazon system and the Orinoco. From Santarem a branch cable is laid to Alemquer, and Obidos, the next station of the main line, is the last point touched in the State of Pará.



Typical Riverside View on the Amazon.

It would not be right to leave unnoticed the rubber-gathering industry, which is at once the wealth and the bane of this part of the world. The implements in use are of the most primitive kind, as may be judged by the samples on the table, but the average earnings can easily be £3 per day during the dry season, and the facility of earning so much money with little exertion makes the inhabitants unwilling to engage in more arduous labour. A narrow path leads from the hut on the water's edge into the forest from one rubber tree to another, the path eventually returning to the hut. The trees are cut on the morning round, and the rubber is gathered in the afternoon. As soon as it arrives at the hut a fire of oily palm nuts (Attalca excelsa) is lighted, and the thin sap thickened in the smoke. For this purpose a paddle is used on to which the sap is poured with a small earthenware or

Digitized by Google

tin vessel. The smoke soon thickens it, and a new layer is poured on until the well-known flat cakes of indiarubber have been formed. Owing to the rise of the river during the rainy season most of the huts have to be abandoned, and it can easily be imagined how comfortless they are. Nearly all of them are built on piles, and most of them are thatched with palm leaves. There is hardly any attempt made to cultivate the soil, such as it is, but everything is imported. The ss. "Cametense," in which the surveying party went out, was laden with cabbages, onions, and potatoes, part of which went as far as Iquitos, in Peru. Chiefly owing to this want of provisions and to the generally careless mode of life, the mortality among indiarubber-gatherers is very great.

There are two stations in the State of Amazonas—Parentins, formerly called Villa Bella da Imperatriz, and Itacoatiara, formerly Serpa. Just before reaching the former station the Serra de Parentins is passed, which forms the boundary between the two states. At Parentins the river makes a sudden bend, and the resulting eddy-current greatly impeded the work; at Itacoatiara, on the other hand, the bow of the ship was run ashore and the end of the cable landed direct from the ship.

No words can describe the luxuriance of the vegetation met with everywhere on the journey better than has been done to perfection in the classical works of Bates and Wallace. Everything they have said in this respect remains as true as it was 40 years ago, and hardly anything new can be added to their description of the general features of the Amazon valley, but the town of Manaos has completely changed its character since it was made the capital of that region in 1853. A town quite European in its features has arisen in the midst of the forests, and to the benefits of rapid transport, to which it has owed so much, there is now added the characteristic lever of modern progress, the annihilator of space and time—electrical communication.

SINGLE-PHASE SELF-STARTING SYNCHRONOUS MOTORS.*

BY F. H. LEONARD, JR.

Every central-station manager who operates an alternating plant has to grapple with the question of power distribution. Applications for power service come in from every direction, and in many cases, properly worked up, would make a more remunerative business than that of furnishing current for lighting purposes. It is, perhaps, unnecessary to point out that the bulk of the lighting service averages but a few hours per day, whereas the motor service covers a much longer period with a corresponding reduction in cost of the current output. The difference is so great that many stations are furnishing current for motor service at 50 per cent. of the price for lighting service, and even at that figure the motor business is the more profitable.

The drawback to the single-phase synchronous motor has heretofore been that it could not be started without some other source of power, and would not carry its load up to speed. Motors are now made in which this is entirely overcome. They start up under load, and can be specially wound to give much greater torque in starting than when running in synchronism.

Two simple, well-known principles are combined in this motor: The principle of the ordinary alternating-current synchronous motor with that of the direct-current motor or generator. The armature has two distinct windings; one, a distributed winding connected to a commutator, similar to that of a direct-current motor or dynamo, which in this motor is used for starting and afterwards for exciting the field. The other winding is of the shuttle type, wound so as to concentrate distinct and regularly alternating poles in the armature, and performs the regular work of rotating the motor armature, advancing it from one pole to the next with each impulse of the generator.

An ordinary double-throw switch on top of the motor is used in starting, there being no resistance or other complicated device, as the self-induction of the windings is sufficient to choke back any abnormal flow of current. In starting, the switch handle is depressed so that the lead wires which conduct the alternating current from the transformers are connected through the switch blades to the contacts which lead the current first to one of the commutator brushes, thence through the distributed armature windings and out through the opposite brushes to a coarse wire winding on the field poles and back again to the switch contacts and binding posts, these connections being identical with those of a direct-current series motor. As soon as the current is turned on, the motor commences to rotate at a constantly accelerating speed until synchronism is reached, which is indicated by the lighting of a lamp located on the switch at a dull red. This is the signal for the reversal of the double-throw switch, which then changes the complexion so that the leads from the transformer are cut off from the commutator and connected to the collector rings and concentrated armature windings, while at the same instant the commutator brushes are connected to the shunt field windings, magnetising the field with direct current, the only office of the commutator after the motor is started and up to speed being to supply the small direct current necessary to magnetise the field.

In starting without load the motors will run up to synchronous speed in from 5 to 15 seconds, depending upon size, windings, etc., and when loaded in from 15 to 30 seconds, taking about the same current in either case, the time factor making the difference in the power consumed, the current taken under these conditions amounting to from 25 to 50 per cent. in excess of what the motor will require when running in synchronism. But when only required to start itself or light countershafting this current may be greatly reduced by special windings.

The direct-current winding delivers a perfectly smooth current, and is not at all pulsating in character. In circuit with the field winding is a rheostat to control the extent of field excitation. This rheostat is located in a recess in the base of the motor, the handle for its regulation being accessible through the oval opening at the commutator end pedestal. The motor, starting switch, and field rheostat are in one piece, making a most simple and compact combination. All that is necessary to instal the motor is to connect the secondary wiring of the transformer to two binding-posts on the motor, and it is ready for operation.

The field crown is of the multipolar type, with field cores pointing inwardly; the magnetic circuit is composed of sectional sheet-iron punchings, each section including two poles, stacked so as to break joints. These punchings interlock and are clamped between two cast-iron rings with bolts passing through from side to side, which serve to clamp the whole together solidly, at the same time holding each punching in its proper place and tying them like links in an endless chain. The bottoms of the cast-iron rings are milled to fit the base of the motor, to which they are firmly bolted.

On top of the field crown is placed a starting switch, and all the electrical connections from fields, commutator, and collector brushes are brought around the outside of the field punchings to the top, concealed from view, however, by the perforated steel jacket, which is held in place by grooves in the cast-iron clamping rings, forming an ornamental finish, and greatly increasing the radiating surface.

As this motor runs at a constant speed, it has been necessary to devise several arrangements to accomplish what might be done by variable speed motor. Motors are made for blowing church organs, in connection with which it has usually been customary to provide complicated automatic speed-regulating devices. With this motor no attempt has been made to vary the speed. The organist closes his circuit and starts his motor by means of a pedal. A blower, driven by the motor, fills the bellows and maintains a constant pressure, usually about 4oz. per square inch. If no air is used, the blower spills the wind out of its fan, and requires only enough power to overcome the friction and maintain the pressure. As fast as the air is used the blower takes a corresponding amount of power, the motor absorbing the current accordingly.

* Abstract of paper read before the National Electric Light Association. From the *Electrical Engineer* (New York).

Digitized by Google

An arrangement for elevator service which is extremely simple has been devised. The constant-speed alternating motor, cable drum, and gearing are all mounted on a single base casting, in which the respective parts are bolted. There is a pinion on the shaft of the motor which engages two bevel gears, each mounted on a sleeve, which also carries one part of a friction clutch, the two sleeves rotating in opposite directions, and the whole being supported by and turning freely on the worm-shaft which engages the worm-wheel that turns the cable drum. The other part of each clutch is keyed to the worm-shaft. The controller wheel is mounted on an extension which is cast on the case that entirely encloses the bevel gears and pinion, permitting them to run constantly in oil. This controller wheel is connected to the controller cables or hand ropes which serve to operate the elevator. A pull on the hand rope turns the controller wheel, rotating it through an arc of 60deg. This rotation serves, first, to release the brake on the worm-shaft, by means of the adjustable link and lever, by depressing the roller which travels over the cam in the controller wheel; at the same time, one shipper fork is moved by the connecting rod at its upper end, which is pivoted near the upper rim of the controller wheel, far enough to cause one of its clutches to engage its other part on the sleeve attachment to the bevel gear, so as to drive the worm-shaft and rotate the cable drum. At the same time the connecting-rod attachment to the shipper fork opposite moves across the centre of the controller wheel without producing more than enough movement to take up the lost motion in the clutch parts to which it is attached. Pulling the hand rope in the opposite direction brings the parts back to their original position, disengages the clutch, and sets the brake on the worm-shaft. Pulling still further in this direction, the opposite connecting rod travels so as to move the shipper forks and engage its clutch, turning the hoisting drum in the opposite direction, while the first-mentioned connecting rod moves across the centre without causing any appreciable movement of the shipper fork. The motor runs continuously in one direction during working hours, and there is no heavy rush of current in starting as with a direct-current series motor, with its tendency to drop the brilliancy of the incandescent lights on the same circuit.

These motors are suited to any frequency in general use in this country, and are wound for from 140 to 60 complete periods per second, the speed being fixed by the frequency of the generator or circuit to which it is connected.

While this motor was designed for single-phase circuits, yet it is obvious that it will work quite as satisfactorily when connected to either leg of a two or three phase circuit, and where such circuits are loaded with induction motors, a few synchronous motors properly distributed and somewhat over-excited would serve to allay the pernicious effects of the inherent lag or idle current which goes with induction motors, at the same time raising the E.M.F. at the extremities of the line, reducing the drop in the conductors, and allowing the generators to do more work, inasmuch they would not be required to deliver so large a wattless current.

This synchronous motor is also a good rotary transformer, and lends itself very conveniently for charging storage batteries and electrolytic work, the alternating current entering at collector rings, while direct currents are delivered from the commutator brushes. For laboratory work and as a piece of apparatus in colleges that teach electric engineering it is invaluable, for, besides the previously mentioned uses, it may be driven by direct currents as a series motor; further, it may be run at a constant speed as a direct-current shunt motor, while from the collector rings alternating currents may be taken at any frequency, dependent upon the speed, which can be regulated by resistance in the field or armature circuits; or, belt driven, it may be used as a self-inciting alternator.

DISCUSSION.*

Mr. Wagner: Mr. President, I should like to ask Mr. Leonard the effect of switching at the central station on the operation of the motor when running at full load. I have had such motors in operation myself, covering a period of three years, and I find that it is an almost insurmountable objection to the use of the synchronous motor, as the frequent switching found necessary to properly divide the load on alternating-current generators causes the motors to fall out of step. I should like to know if he has covered that point.

Mr. Leonard: What Mr. Wagner says is quite true. If a motor fully loaded has the current switched off, it will slow down to a point so much below synchronism that it is impossible to go on unless the switch be reversed so as to put it in the position of starting. In most stations where these motors have been used the circuits on which the motors are run are not switched, except at hours when the motors are not in service, or it is done while the machines are in multiple, preventing the breaking of the circuit and the cutting off of the current.

Mr. Van Trump: Mr. President, I should like to ask Mr. Leonard if there is not a difficulty in operating those motors due to a difference in the curve—that is, in the wave-line of the motor differing from the generator. I have operated synchronous motors to some extent, and I find there is considerable difficulty in getting any motor to work in this way, due to the difference in the character of the curve of the generator making a fluctuation.

Mr. Leonard: These motors, Mr. President, are wound, as stated in the paper, with a concentrated winding—that is, what is known as the iron-clad winding in alternating-circuit phraseology, and while they operate with a greater torque, that is the ultimate point at which they will fall out of step. The utmost load they will carry with an iron-clad armature is about 15 per cent.—10 to 15 per cent. greater with an iron-clad motor than with a smooth bore winding. Most of the single-phase alternators in general use now, however, are wound with the iron-clad winding, and the only difference that would occur would be that the maximum taut, the limit of the load, would be a little lower with a smooth bore winding than with an iron-clad. The wave-line makes no difference.

Mr. Ferguson: Mr. President, I should like to ask the gentleman a question. I wish to know if there is not a danger, in case that machine was started up on a light load, and the operator did not fix the switch in time, of allowing the machine to accelerate its speed to such an extent that it would go all to pieces.

Mr. Leonard: That would happen if it were allowed to be carried on to a sufficient extent. The instructions going with the motor state that the switch should be reversed the moment the lamp on top of the switch, directly in front of the man whose hand is on the handle—just the moment he sees that light his instructions are to reverse the switch. If he fail to do that, and there is no load on, the acceleration of speed might go on, as Mr. Ferguson suggests, to an extent sufficient to throw the armature windings out and injure them. We have had very few cases of that, however. The thing has occurred, and it might occur with a careless hand; but if a man does it once, he never does it again.

Mr. Wagner: Mr. President, I should like to refer again for a moment to the question of central-station switching. It is found necessary to divide the load between a great number of generators at certain times of the year, quite early in the afternoon, long before the motor load is taken off; in other words, at a time of the year when the day and night loads overlap, and it seems hardly possible to delay such switches to such times of the day—say, after six o'clock—when the motors are generally not in operation. Mr. Leonard admits that the motor must stop if any such switching occurs at the station. His reference to stations where generators run in multiple applies to plants which are very recently installed or in process of installation. Until the last few months, I might say, there has been practically no place in the country where stations were operated in multiple. We are anxious for a motor that will operate on existing stations and under existing methods, and it seems to me he fails to brings that point out very clearly—how such stoppages of the motor service are to be prevented.

Mr. Leonard: In practice, we have not had very much objection on account of the feature mentioned by Mr. Wagner. Of course, if circuits are switched when the motor is loaded, and the phases are not exactly coincident in both generators, which is hardly likely to be the case, the motor will fall out of step, but it seems to me that it might readily be arranged so that feeders supplying the motor power could be handled in such a manner that it would be unnecessary to switch very much during the hours of the motor load. In the little experience that we have had we have found no great objection upon that point. In some cases it has been necessary to switch—for instance, at thunder shower, or something of the kind coming up, and darkening everything suddenly, then it has been necessary to switch. But the attendants at the central station generally know which circuits these motors are on, and they endeavour in most cases to avoid switching the motor circuit. It is an easy matter, however, in case the motor is thrown out of step, by cutting off the current for a few seconds, to start the motor again, and it is a matter that takes only a few seconds, and as there is a great demand for these motors, people are willing to put up with that slight objection, or adjust their conditions so as to avoid this difficulty. At least, that is what we have found.

Mr. Wagner: I wish to say, Mr. President, that I do not make these criticisms as reflecting at all upon Mr. Leonard's motor, but merely from the fact that I have had motors of exactly the same type in operation for the last three years, and have finally decided that I would have to give up work in that line, as such objections seem to be insurmountable in ordinary practice. I admit that I failed to solve the problem myself.

THE WENSTROM ALTERNATE-CURRENT MOTOR.

The inventor of this type of alternate-current non-synchronous motor was an early worker in the field of motor design, and his patent will be found to be exceptionally clear and lucid. The results of his research and practical experience in the matter are now laid before the English public, as Messrs. Fuller and Co. have taken up the sole agency for the supply of these motors. As referred to above, these motors are of the non-synchronous type, with squirrel-cage armatures, as shown in Fig. 1. The armature,

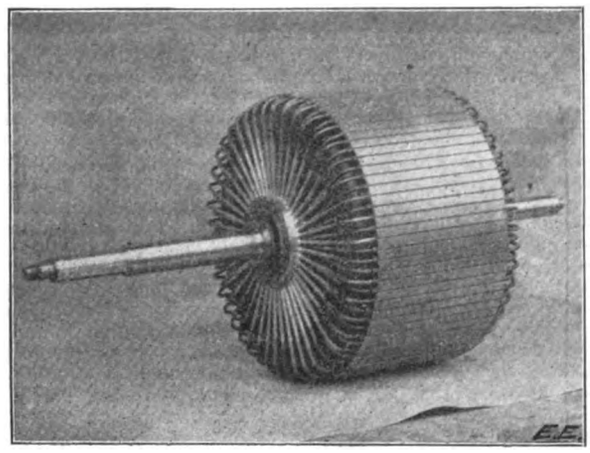

FIG. 1.—Armature of the Wenstrom Motor.

or, as some writers prefer to call it, the rotor core, is made in a similar manner to that of a direct-current drum armature. The conductors are threaded through holes in the periphery, and are then all connected together at the ends by being sweated into gunmetal rings on the shaft. The inductor is similar in design to others described before in our columns. The diagrams of connections when starting and in full work are shown in Fig. 2. The difference of

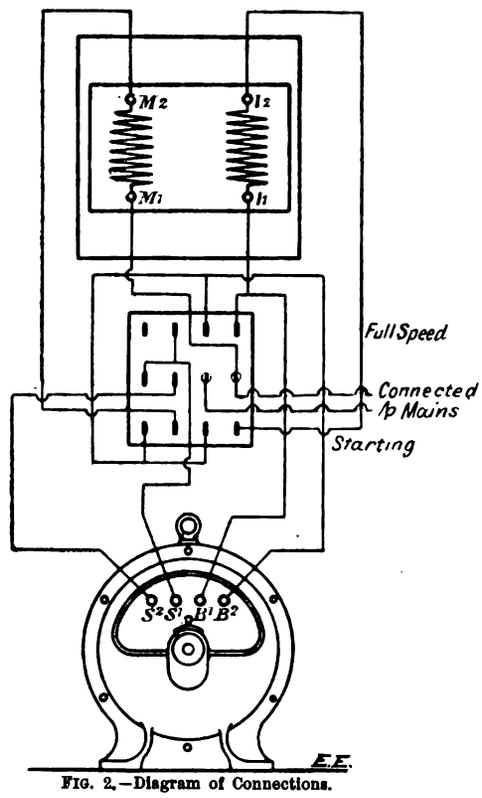

FIG. 2.—Diagram of Connections.

phase required to start the motor is produced by the use of differentially-wound choking coils. When the motor has attained a considerable speed, the switch is thrown over and the one circuit in the inductor is connected direct to the main, while the other is short-circuited. The trouble with such motors lies in the fact that they will not start under load. This difficulty has been most ingeniously overcome in the present case by an automatic clutch gear in the pulley (Fig. 3). The pulley, A, is not keyed to the shaft, but is free to revolve independently of it. The inside rim of the pulley is lined with leather, B. A boss, C, having a number of radial spokes, E E, is keyed to the shaft, and on these spokes a number of weights, D D, are carried. When the motor is at rest these weights are kept in close to the shaft by compressed spiral springs, which can be seen in the figure. As soon as the motor gains speed the centrifugal force causes these weights to fly out and to press against the leather rim. The whole pulley is thus driven, and at the normal speed the driving is absolutely without slip. The following test of one of these motors was recently made at the manufacturer's works in Sweden, and will be of interest to our readers. The speed of the motor, which was rated at ½ h.p., was 3,000 at a frequency of 100. This fell to 2,800 revolutions at full load. The

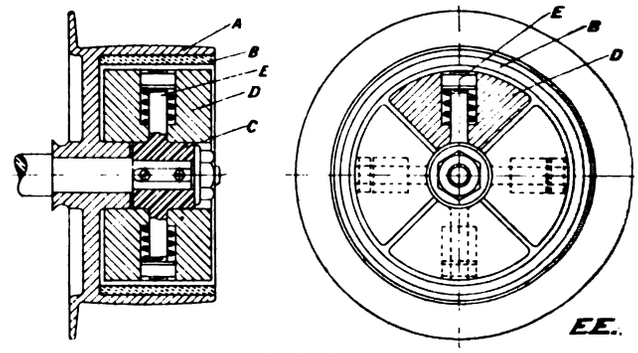

FIG. 3.—Details of the Patent Clutch Pulley used with the Wenstrom Motor.

current taken was 6·5 amperes at 100 volts, and as the power factor was found to be be 85 per cent., the commercial efficiency works out at 68 per cent. This is good for such a small output.

These motors may be seen at work at 28, Bush-lane, Cannon-street, and we are informed by Messrs. Fuller and Co. that the prices will compare favourably with those of other alternate-current motors in the market.

PROF. EWING ON HYSTERESIS.

The Friday night lecture at the Royal Institution last week was delivered by Prof. J. A. Ewing, and was on the subject of hysteresis.

PROF. EWING began with the remark that he believed it was just possible that there might be one or two among his audience who did not know what the subject of his lecture really was. He had been credibly informed that the hall porter had been consulted on the matter, and that a lady had expressed the hope that it was something about hysterics and hypnotism and the whisperings of the angel Gabriel. He much regretted that he had no information to give them in that direction. Moreover, in the *Academy* he had found the subject of his lecture referred to in the "Science Notes" as "a term of art of engineering, we presume, but which is not to be found in Ogilvy's 'Imperial Dictionary.'" On the other hand, in a technical journal of the same week, he had noticed that Prof. Kennedy had said that there was hysteresis in everything. Now, which of the two was right, the writer in the *Academy* who could not find hysteresis anywhere — not even in Ogilvy's "Imperial Dictionary"—or Prof. Kennedy, who found it everywhere? He thought the truth lay with Prof. Kennedy. According to the papers, there had just been an all-night sitting of the House of Commons and an all-day standing of the Great Wheel. That showed that those two institutions did not work without a certain amount of internal friction; and it was his purpose to show that night that it was in the development of a kind of internal friction that hysteresis consists. Some years ago, in the course of a series of experiments on elasticity, it was borne in upon him that there were a large number of different phenomena which presented the common feature of being really due to a "tendency to the persistence of previous conditions." It was to this tendency, this inherent conservatism of materials, that the name had been given of hysteresis—a word whose derivation was occasionally the subject of mistake, but which, he might say, was formed in a perfectly regular and legitimate manner from a Greek verb signifying to "lag behind," because owing to that conservatism the result did not keep up with the cause of it. One of the earliest examples of this, which was

Digitized by Google

actually the subject of experiment, was that if a magnetised iron wire was put under a stress—in fact, pulled—and then relaxed, and pulled and relaxed again, and so on, the magnetism changed by a definite amount with the pull, and returned to its old value when the stress was removed, but the intermediate values were not the same as the pull was put on and taken off, so that if the half-way values of strain were taken it would be found that they did not give half-way values of change of magnetism. [This was shown experimentally.] But it was not a hysteresis of this kind, or that which they found to occur in other physical properties, that he was to speak of that night, but it was the hysteresis to which the name was specially applied—namely, that which occurred in the magnetising and demagnetising of iron by means of the electric current, or, rather, as was the more general case, not only demagnetising it, but reversing the direction of magnetism. The "lozenge" hysteresis diagram was here thrown on the screen, and the lecturer explained that such a closed curve represented the dissipation of a certain amount of energy. That was a matter which had of late attained a high degree of practical importance, because wherever they had the alternate-current system of electric lighting they had the iron cores of the transformers being carried through this cycle of magnetising, demagnetising, magnetising in the reverse direction, and demagnetising again something like a hundred times a second night and day. He had stated before that in the course of this cycle hysteresis caused a dissipation of energy, which took the form of heat wasted in heating the cores of the transformers. It had thus resulted that though when it was first invented "hysteresis" was a term of pure physics, it had now become a term of engineering. With the aid of diagrams on the screen, Prof. Ewing then explained the principle of the magnetic curve tracer which he had on the table. A stretched wire carrying a current was attracted by the specimen core to be magnetised, and its deflection caused a small amount of revolution about a horizontal axis in a mirror connected to it. By a simple arrangement the mirror was further twisted on an axis at right angles to this by the magnetising current. It resulted from this that the spot of light reflected on the screen from the mirror would describe a curve in which the X ordinates were proportional to the magnetising force, while the Y ordinates were proportional to the magnetisation produced. If the course of the spot were followed on the screen, it gave a hysteresis curve of the characteristic shape. The varying form of the curve was here shown, as the degree of magnetisation was varied, and the lecturer then remarked that the practical importance of a means of measuring hysteresis was due to the large quantity of it that was constantly going on in transformer cores. It was no use to burn coal at the central station in order to produce useless heat in the transformer cores, and, therefore, it was important to get iron for the latter which gave as little hysteresis as possible. To do that they must be able to test their iron for hysteresis. He had before him three specimens, each of which had been sold as "soft iron," but of which each gave a widely different value when tested, and one of which was so bad that from an electrical engineer's point of view it ought not to be called soft iron at all. A diagram of a practical hysteresis tester which was on the table was here thrown on the screen, and it was explained that the principle of the instrument was the rotation of the specimen piece to be tested between the poles of a C-shaped magnet balanced on knife-edges. Under the influence of hysteresis, the magnet was deflected in the direction of the revolution of the test-piece, and from the amount of the deflection the hysteresis could be determined. Though not so conveniently for the purpose of measuring, hysteresis might be inferred from the amount of heating produced in the iron, and this led the lecturer to refer to the electric kettle of Mr. Pyke and Sir David Salomons, a specimen of which was on the table. In this, a quantity of small coils containing "hard" cores were arranged under the bottom of the kettle. If the coils were connected up to an alternating current, the cores became heated under the influence of hysteresis, and the heat was transmitted to the bottom of the kettle, and the water in it was caused to boil—or, at least, he (the lecturer) was told it might be. What would be the cost of obtaining enough hot water for a cup of tea by this method he had no figures to show, but such as it was he believed that to be the only case in which there had ever been any useful application of hysteresis. After one more experiment in which the rolling of a steel ball was shown to be checked by hysteresis, when the ball formed part of a magnetic circuit, the lecturer proceeded to the theory of the subject. Exactly five years ago, when lecturing at the Royal Institution on the subject of magnetism, he had had occasion to point out that the phenomena exhibited in the process of magnetising iron could be accounted for on the supposition that the iron in its intimate structure consisted of a great number of groups of very little magnets, and the process of magnetisation consisted essentially in a rearrangement of these groups, so that the little magnets came to point, not in all directions, but in one direction. The groups of elementary magnets were highly stable, so that any process which broke them up would, in general, involve a dissipation of energy and an amount of hysteresis. Now, there had recently been an interesting confirmation of the theory of the nature of the process of magnetisation. The magnetism of a piece of iron could be reversed in two different ways. One way was to reverse the field, leaving the iron stationary, as was done in a transformer, where the current was constantly being reversed in the coil surrounding a fixed iron core. The other way was to turn the iron round in a stationary field, and it was this kind of reversal of magnetism which took place in the armature of a dynamo. Now, it had been objected against the theory he had mentioned that it would lead to the absurd result that if the field were only strong enough there would be no hysteresis when the magnetism of a piece of iron in it was reversed by the second method because the elementary magnets would be absolutely mastered by the force of the field and held firmly in one direction, so that there could be no regrouping of them, and consequently no hysteresis. That had been considered an impossible result, and a difficulty in the way of the theory. Lately, however, Prof. F. G. Baily had been experimenting on the question, and had found that when rotated in a very strong field iron did not exhibit hysteresis. So that the result, which was so contrary to preconceived ideas that it was considered as an objection to the theory, turned out on examination to be true. In illustration of the theory a model was shown, consisting of a quantity of small magnets free to revolve about their centres. Left to themselves, these magnets arranged themselves under their mutual attractions in such a way that their poles pointed in different directions. If a field of gradually increasing strength were produced by an electric current the original grouping was broken up, the little magnets swinging into the direction required by the field, not all at once, but gradually as the strength increased. Ultimately, when they all pointed in the same direction, there was a condition of things which corresponded to magnetic saturation, when no further magnetisation could be produced by increasing the magnetising force, because all the elementary magnets capable of direction had been directed. It was also shown—though probably from considerations of time the point was not insisted on at any great length—that when the groups broke up to rearrange themselves the process in each group was not a gradual but a sudden or catastrophic one, and therefore produced a dissipation of energy. A modification of the model capable of rotation illustrated Prof. Baily's result. In no field the little magnets revolved as a whole without rearrangement, there being nothing to disturb their natural grouping, while in a strong field they continued always pointing in the same direction, however rapidly they were carried round, so that again there was no rearrangement; but with intermediate strengths they began to revolve as a whole as in the first case, but as soon as the deflection with regard to the field became considerable, the groups begin to break up and rearrange themselves. Prof. Ewing then called attention to a curve diagram in which the results obtained by Prof. Baily were embodied. [In the diagram the ordinates representing the hysteresis obtained by alternating the field increased continuously with an increase of magnetising force, the curve tending apparently towards an asymptote lying at an angle between the X and Y axes, while in the case of rotation, though the ordinates at first increased faster than in the former case, they attained a maximum and the curve turned over, and cutting the first curve came down again towards the axis of X.] Lastly, returning to general considerations, the lecturer threw out the suggestion that it might be possible to explain a number of other phenomena in physics by means of conceptions similar to those above. For instance, when one body rubbed against another they had the well-known effects of mechanical friction. Those might really be the consequence of the breaking up of stable groups of molecules in the rubbing surfaces under the influence of some species of polarity—conceivably, for instance, of electrostatic polarisation. In conclusion, if some of his hearers had found themselves engaged in digesting the meaning of one sentence while he (the lecturer) was already well on his way through the next one, he hoped that they would look upon it in the light of a necessary hysteresis result, because the time limit imposed on a Royal Institution lecture was all too short a one in the view of the lecturer.

INSTITUTION OF ELECTRICAL ENGINEERS, May 28.

At last night's meeting the following candidates were balloted for:

Members.—**A. B. Larkins, Indian Government Telegraphs; Richard Threlfall, Hollowforth, Lancashire, England, and Sydney, New South Wales.**

Associates.—**John Henry Alexander, Dundonald, by Kilmarnock, Scotland; Gordon Bryant, 32, Camperdown, Great Yarmouth; Henry Conner, Electric Lighting Station, Shrewsbury; Alfred T. Cummins, Electric Lighting Station, Belfast; Herbert H. B. Deane, care of Messrs. Verity and Son, 31, King-street, W.C.; Hugh Hellman, 62 and 63, Central-buildings, Johannesburg, S.A.R.; George Arthur Morton, 22, Ridley-villas, Newcastle-on-Tyne; Hubert Russell, 31, King-street, W.C.; Thomas H. M. Swinburne, Woodlands Park, Altrincham.**

Students.—**Trevor Duesbury, 106, Rose Hill-street, Derby; Herbert Durtnall, Cannon-street Hotel, E.C; Theodore Arnold Locke, Walton-grove, Chesterfield; Robert A. D. Macalister, Faraday House, Charing Cross-road, W.C.; Hubert Sadler, Cannon-street Hotel, E.C.**

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

WILLANS AND ROBINSON.

We believe it was Froude, in one of his essays, who pointed out the great difficulty in obtaining accurate history. It would be interesting if some Mahatma or equally learned person would describe to us of the nineteenth century the struggles of the historian of the twenty-fifth century to find out what was correct and what was incorrect about this year of grace 1896. Surely, one of our descendants, in the attempt to reconcile, say, the statements of the *Chronicle* with those of the *Standard*, would fail, and if the trouble in getting at the truth of political and social questions is Herculean, what about the trouble in getting at the truth about scientific questions? So far as we are concerned, we do not hesitate to say that the firm which has played most part in the development of the high-speed direct-driving engine for electrical work is that of Willans and Robinson. Whatever may be the claims of other builders—and they are many and important—we must contend that in the early days of the era of electric lighting Mr. Massey, Mr. Crompton, and Mr. Willans conferred ofttimes about the adaptation of the then Willans engine to electric lighting purposes. We are writing from memory, but if our recollection of the then state of affairs is correct, it was Mr. Massey who took the initiative in the matter in that he foresaw the necessity of such an engine, and, knowing Mr. Willans and his engine, thought that it might be adapted to the purpose in view. The ardour with which the late Mr. Willans threw his great talents into the solution is known to the world. His papers show the grasp he had of the whole subject, and since his untoward death Mr. Robinson has continued in the path marked out by the then partners, to the immense benefit of the electrical industry. These are facts which, we think, can hardly be disputed. At that early period there existed at Thames Ditton a small works owned by men of superior intelligence. The rise of electrical work was their opportunity, and they eagerly and successfully seized that opportunity to move along the road which led to fortune. Success meant larger works and increased capital. These were obtained; but the tide still flows, and the works at Thames Ditton have proved in the larger sphere of operations to be somewhat misplaced. Business men connected with big works know full well that geographically a works may be unsuitably placed. The position that answered very well under one set of circumstances does not answer so well under other circumstances. Thames Ditton might do admirably as a centre to build launch engines, but not for the larger work of electric light engines. The increase of the capital of a company is seldom of sufficient importance to deal with as we are now doing, but we feel that exceptional features are here before the public. The firm and the existing company have developed a business which is somewhat phenomenal in character. They are shifting their works, increasing their plant, and asking for further capital in view of the increasing demands. There is no doubt, so far as science and practice can see at the present moment, but that electric lighting

Digitized by Google

and electric power distribution will continuously increase, even in a greater ratio than the increase of the past ten years. So long as land is valuable and space is thereby restricted, the class of engine developed by Willans and Robinson must be largely used; and these makers, who have done so much up to the present, will surely not allow competitors to take their places in the race, but will hold their own increasingly. Assuming, then, that the energy and talent now shown in carrying on the works will continue, there seems no safer investment in the market than the one offered. Indeed, we should not be surprised to learn that the issue was covered many times over.

IS IT POSSIBLE?

A letter in the *Times* of Thursday describes some high-handed proceedings of the National Telephone Company—at least, they would be described as such if the facts are correct as stated. The sentences which describe the proceedings are as follows: "Sir,—My experience with regard to the proceedings of this company is similar to that related by your correspondent Mr. Barham in the *Times* of Saturday. Some months ago I found their men setting up poles near my property here, and one who acted as foreman told me that they were going along the main road, which passes through it, by the authority of the county council. I forbade them to enter on my land unless the company first gave me an undertaking, countersigned by the county council, similar to that volunteered by the Postmaster-General when the telegraph line was made. Without any such undertaking they set up their poles for a mile along the road, obstructing the footpath itself where there was no margin by its side."

The company, we are told, caved in upon the gentle remonstrance of a lawyer, put their poles where they were permitted to go, and pay a way-leave. The queer part of the story is to be found in the following sentence: "Their policy—shrewd, if not honest—is to count on the supineness of landowners—who, I believe, lose their rights if not asserted within six years—and on their ignorance, in many cases, that the centre of the road, not the side, is the boundary of the adjacent fields." Landowners ought not to be ignorant of the law upon any matter which affects their property; but if they are, it should not be possible under any circumstances for a trespasser to become a permanent resident after once his trespass has been ascertained.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

June 2, 8 p.m.—At Great George-street, Westminster, S.W. Annual general meeting (corporate members only).

Institution of Electrical Engineers.

May 29, 4 p.m.—At 28, Victoria-street, S.W. Business meeting (members only).

Institution of Junior Engineers.

May 30, 10.30 a.m.—Visit to the Fowler-Waring Cables Works, North Woolwich.

Liverpool Engineering Society.

May 30.—Visit to the Chorley Reservoir.

CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS, 1896.

ELECTRIC LIGHTING AND POWER.

ORDINARY GRADE.

Instructions.

The candidate must confine himself to one grade only, the ordinary or honours, and must state at the top of his paper of answers which grade he has selected. He must not answer questions in more than one grade.

If he has already passed in this subject in the first class of the ordinary grade, he must select his questions from those of the honours grade.

Candidates for honours must have previously passed in the ordinary grade. They may select their questions from Section I., electrical instruments; or Section II., dynamos, etc.; Section III., electric light and power; but they may not answer questions in more than one section.

The number of the question must be placed before the answer in the worked paper. Not more than 10 questions to be attempted in either grade.

1. What is a choking coil? Why will it not choke a steady continuous current?

2. Define one watt, one kilowatt, and one horse-power. Also, if 1ft. = 30·48cm., and 1lb. = 453·6 grammes, calculate the number of ergs equal to one foot-pound at a place where the acceleration of gravity is 981cm. per second. Lastly, calculate the number of ergs per second equal to 1 h.p.

3. Explain what is meant by the statement that in an inductive circuit an alternate current is out of phase or step with the E.M.F.

4. Why are alternators so commonly separately excited? How can they be made to be self-exciting?

5. What is the difference (*a*) in connections, (*b*) in construction, between a shunt-wound and a series-wound dynamo? Why are arc lighting machines not generally shunt wound?

6. Why is it dangerous to lift the brushes of a shunt-wound dynamo when shutting down? State what would occur if you were to lift the brushes of a running shunt-wound dynamo (*a*) while a fair load of lamps are being supplied; (*b*) when no current is being supplied to the external circuit.

7. Calculate the number of (alternating) volts needed to drive an alternating current of 10 (virtual) amperes through a choking coil having a coefficient of self-induction of $\frac{1}{100}$ henry, the frequency being taken at 80 periods per second.

8. Is the flesh side or the hair side of a leather belt run against the pulley of a dynamo? Give reasons. Also state what advantages there are in rope driving over belt driving.

9. Give a sketch, or sketches, to illustrate the winding of a drum armature for use in a four-pole field.

10. State how much is (approximately) the rated power of motors used in electrical tramcars. Also state on what it is, in an electric motor, that the torque or turning moment depends.

11. How would you test the number of watts per candle required by any glow lamp? How much would you expect these to be in lamps whose average life is 1,000 hours?

12. Describe briefly any kind of supply meter with which you are familiar. What types of meter are most likely to register with small loads? Give reasons.

13. Make a full-size hand-sketch of a quick-break switch.

14. It is required to charge 55 accumulators (ordinary sort, with lead, etc., plates) whose ordinary rate of discharge is 100 amperes. There are available four dynamos of following sorts: (*a*) a series dynamo, 50 amperes at 130 volts; (*b*) a series dynamo, 100 amperes at 50 volts; (*c*) a shunt dynamo, 50 amperes at 130 volts; (*d*) a shunt dynamo, 100 amperes at 50 volts. Which one would you employ, and why?

15. It is found that a motor (shunt-wound, separately excited, or series-wound) that is supplied from mains at

Digitized by Google

constant pressure runs faster if its field magnet is weakened. Explain (1) the reason for this fact; (2) what arrangements you would make to weaken the field magnet in the case of each of the three sorts of motors mentioned.

16. Point out in what way the pressure at the secondary terminals of a good transformer depends on that at the primary terminals and on the respective number of windings and their resistance. A transformer with a well-closed magnetic circuit is taking 10 amperes at 2,050 volts. Its primary coil consists of 860 turns of wire having a total resistance of five ohms. Its secondary consists of 43 turns, with a resistance of $\frac{1}{80}$ of an ohm. Assuming that magnetic leakage, eddy currents, and hysteresis are negligibly small, calculate the pressure at the secondary terminals when 200 amperes are being supplied to the lamps.

17. What is the rule for calculating the "intensity" of the magnetic field in the middle of a long tubular solenoid? If the winding is uniform all along, what is the intensity of the field at the open ends as compared with that in the middle? Where must an iron bullet be placed so that the force exerted on it by the solenoid shall be a maximum?

18. What is the three-wire system of distribution, and why is it used? If any one of the three wires is to be earthed, which one would you select, and how would you "earth" it.

19. Give a sketch, roughly to scale, showing parts full size, of a d'Arsonval galvanometer, and describe particularly how the current flows through it.

20. Briefly describe the Clark standard cell.

Honours Grade.

Candidates in honours must have previously passed in the ordinary grade. They may select their questions from one only of the following sections.

Section I.—Electrical Instruments, etc.

Answer questions Nos. 2, 7, and 19 of the ordinary grade, together with not more than *five* of the following:

21. Show the connections for a potentiometer to test E.M.F.'s from 1 up to 1,000 volts, and currents from 1 up to 1,000 amperes.

22. What temperature errors are likely to exist in hot-wire voltmeters?

23. In alternating-current instruments of the solenoid and core type, does any error come in from any of the following causes: (*a*) eddy currents in the core, (*b*) eddy currents in the bobbin, (*c*) hysteresis in the core, (*d*) heating in the core? If there are any errors at all from these causes, which way will they affect the readings?

24. Give a brief description of (1) any kind of alternate-current meter which measures the energy; (2) any kind of continuous-current meter which measures the time-integral of the current. Say what kind of errors might be expected in each.

25. Discuss the principle of the magnetic brake used in so many meters; and point out (1) why it is so much more trustworthy than any other kind of frictional device; (2) what are the necessary conditions that its retarding drag shall be accurately proportional to the speed?

26. What standard of light would you use in a photometer for testing glow lamps. Give reasons for your choice.

27. There are several kinds of photometer of greater sensitiveness than the old Bunsen grease-spot photometer. Describe the arrangements of the one best known to you.

28. Describe a set of apparatus suitable for showing Tesla's high-frequency experiments, the source of supply being the ordinary alternate current at 100 volts. State the sizes of the wires and the special modes of insulation adopted.

Section II.—Dynamos, Motors, Lamps, etc.

Answer questions 7, 9, and 14 of the ordinary grade, together with not more than *five* of the following:

29. Show that in an armature there is no appreciable mechanical force upon the conductors, due to the current in them, if they are embedded in holes in the core discs.

30. What is meant by the "skin effect" in conductors carrying alternating currents? What is it due to? Is the skin effect appreciable (*a*) in a large transformer wound with solid rod as secondary? (*b*) in a large dynamo whose armature has solid copper rods embedded in the iron?

31. Why is the "drop" or want of regulation in a transformer more marked when it is working on an inductive circuit than on a circuit where the load is purely non-inductive?

32. What must be the value of the (alternating) magnetic flux in an iron core if, with a frequency of 100 periods per second, it is to generate 40 volts (alternating) in a coil of 100 turns surrounding it? What cross-section of iron would be suitable to carry this alternating flux or total field?

33. Describe the armature of a motor suitable for a tramcar, giving rough sketches showing the general dimensions and scheme of winding.

34. What are the difficulties in running transformers of different sizes in parallel at various loads?

35. Give an explanation in your own language of how a two-phase ("double-current") or a three-phase ("triple-current") motor works.

36. Discuss briefly the effect, if any, of the form of the wave of an alternating pressure upon the efficiency of transformers.

37. Explain the synchronous running of two alternators on the same circuit. If one of the alternators is running as a motor with a constant load, show under what conditions the current will be a minimum.

38. Why is there any difficulty in running two arc lamps (continuous current) in series on 100-volt mains? What is the inherent property of the arc itself that occasions this difficulty? What are the essentials of success in lamps for this service.

39. Describe one of the special kinds of motor-dynamo used for equalising pressures in a three-wire system of distribution.

40. Give a brief account of one recent method of reducing cross-induction in continuous-current dynamos, or of eliminating the disturbing effect on the brushes of its variation when the load varies.

Section III.—Lighting and Power Supply.

Answer questions 3 and 10 of the ordinary grade; together with not more than *six* of the following:

41. In a central station supplying continuous current on the three-wire system, what arrangements would you adopt to keep the pressure constant at the consumers' lamps?

42. Discuss the defects and advantages of the various systems of laying low-pressure mains for continuous-current supply.

43. What arrangements would you recommend for coupling large direct-driven continuous-current generators in parallel?

44. Give a sketch of a system of steam-pipes from three boilers to feed five engines.

45. Does electrical energy from waterfalls cost nothing? If not, how would you arrive (approximately) at its cost per kilowatt-hour?

46. Describe any surface-collection or "closed-conduit" system of electric traction known to you?

47. Describe the kinds of trouble that have been occasioned to water-pipes and gas-pipes by badly-designed or badly-constructed electric tramway systems. What arrangements must be adopted in a trolley line with return by the rails to ensure that troubles of this kind shall not occur?

48. A power-house for electric lighting is being erected on a clay soil. What special points must be attended to as to foundations, type of engines, boilers, and furnaces, etc., to prevent nuisances arising to neighbouring properties by reason of vibration, etc.?

49. Give a short description of the electrical features of the Niagara generators.

50. Describe, with sketches, the load curves for a summer day and for a winter day of any lighting station with which you are acquainted. Point out how far the use of accumulators is, or might, in the particular case of this station prove to be an economy (*a*) as regards coal bill; (*b*) as regards wages bill; (*c*) as regards total cost of generating.

THE UTILISATION OF WATER POWER, ESPECIALLY WITH A SMALL FALL, WITH SOME EXAMPLES OF PLANTS FOR THE GENERATION OF ELECTRICAL ENERGY.*

BY ALPH. STEIGER.

The cheap production of electrical energy is generally recognised to be one of the chief aims of modern engineering science. Nature has provided us in water power with one of the best possible agents for realising this object, and I trust that, in bringing the subject of the utilisation of this free gift of Nature before the members of the Institution of Electrical Engineers, I shall be able to convince them that the water powers of this country, if judiciously utilised, are capable of rendering them great service. In my own country—Switzerland—the electrical engineer is co-operating cordially with the water-power engineer, and electrical installations are rapidly increasing in number. The successful electrical transmission of power to points far distant from its source has been the chief factor in this development. The idea prevails that considerable fall is required to obtain water power, but it is my desire to show and to prove in the following remarks that excellent results are obtainable also with a very low fall—a fall of even less than 3ft. Small falls are more frequently met with in this country than high falls, and will, therefore, have more particular attention in this paper than the high falls found in mountainous districts. The description of a few turbine plants under low falls, some of which are applied to the generation of electrical energy, will be of special interest.

During a long experience in constructing turbines and designing complete plants, I have found that the most difficult were always those connected with the utilisation of a low fall. These difficulties consist chiefly in the variation within very wide limits of both the quantity of water and the fall, while a constant power, and in most cases a constant speed, is of great importance. Generally speaking, the real agent in water power is gravity, and the water is simply the medium to transmit the action of gravity on to the motor which converts it into mechanical work. The action of gravity can take either the form of dead-weight, or of pressure, or of velocity, sometimes called kinetic energy. A very high efficiency is obtained from motors in which the water acts by dead-weight or by pressure, but the slow speed of the waterwheels and the complicated mechanism of the pressure engines render them unsuitable for the purpose of generating electricity; moreover, motors worked by weight or by pressure are only advantageous when working under a high fall. The kinetic energy is the only form in which the gravity can be applied advantageously to the performance of mechanical work under a small fall. The motors using it in this form are the common undershot wheel, the Poncelet waterwheel, and the turbines. It will be sufficient for the purpose of this paper to give the efficiency of the various types of water motors for any fall, without going into a detailed description of those which are unsuitable for driving dynamos. The efficiency of the motors, with the fall for which they are adapted, is as follows:

Fall. Feet.	Efficiency of waterwheel.	Per cent	Efficiency of turbine.
			Per cent.
1 to 5	Ordinary undershot ...	25 to 30	
	Poncelet	65 to 70	70 to 75
	Sagebien	65 to 75	
5 to 8	Low breast	30 to 50...	75 to 80
8 to 15.....	High breast	60 to 75...	75 to 80
15 to 50 ...	Overshot wheel	65 to 75...	75 to 80
Above 50...	Pressure engine.....	75 to 85...	75 to 80

These figures show the interesting fact that, the smaller the fall is, the greater is the gain in power over the old-fashioned waterwheels. Although the smallest fall which would reasonably be utilised by a turbine is at least 2ft. 6in., I will show by some examples that by a turbine suitably constructed and carefully adapted useful power is still obtained under a fall of only 1ft. or a little over. The great variety of fall, water supply, local conditions, and special requirements, of necessity demands a variety of types of turbines.

Turbines are classified, according to the manner in which the water acts in them, into (*a*) "impulse," or "action," turbines, and (*b*) "reaction" turbines; and according to their construction, into (*a*) parallel-flow turbines, (*b*) radial-flow turbines, (*c*) mixed-flow turbines. There is an essential difference between the "impulse" turbine and the "reaction" turbine, as indicated by the form of vanes illustrated in the diagrams (Fig. 1 and 2).

The "impulse" turbine, as usually constructed, must run clear of the tail water, its buckets being only partially filled with water. It requires a constant fall, with constant level of the water in the head and tail race, but its efficiency is not affected by the greatest variation of the water supply. On account of this quality, it can be built as partial injection turbine, to utilise high falls with a very small water supply.

* Paper read before the Institution of Electrical Engineers, May 28,

If constructed as "partial injection turbine," its diameter can be chosen so as to give just the desired number of revolutions. This is extremely convenient for driving dynamos, which can thus be connected direct with the shaft of the turbine, doing away with intermediate gearing or belt drives. An instance of this kind is the turbine plant now being erected by Messrs. Escher, Wyss, and Co., of Zurich, at the Falls of Foyers, for the British Aluminium Company, Limited. This plant consists of five "impulse" turbines with vertical shaft, with partial injection, each giving 700 b.h.p., working under a fall of 350ft. The dynamos are required to run at 140 revolutions per minute, and to obtain this speed the turbines were given a diameter of a little over 9ft. Partial injection turbines under a high fall are sometimes fixed on a horizontal shaft, and can thus be coupled direct to the armature spindle of a dynamo by means of an isolating coupling. This mode has been adopted, amongst numerous other plants, for the electric lighting installation of Davos, in Switzerland, which consists of three horizontal patent turbines of 200 b.h.p. each, working under a fall

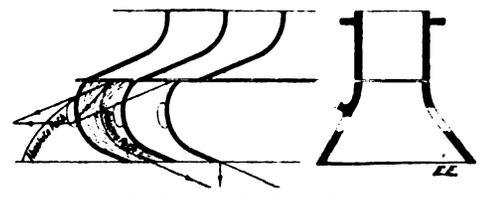

FIG 1.—Vanes of "Action" Turbine.

of 330ft., and running at 400 revolutions per minute. The turbines have a diameter of 40in. As a contrast to these turbines of large power and small diameter, and to show the adaptability of the partial injection turbine to special requirements, the 140-h.p. turbines of the waterworks in Chauxdefonds may be mentioned. These work under a fall of only 170ft., but as they are driving pumps at the low speed of 60 revolutions they had to be made of a diameter of 15ft. Great as the advantages of the "impulse" turbines are under the conditions above mentioned, their use under very low falls is limited, firstly, owing to the reason already given that they must run clear of the tail water—a condition which can seldom be realised in a flat country like this; and, secondly, because they run at a slower speed than a "reaction" turbine under the same fall. Although "impulse" turbines are now built to run in the tail water without considerable loss of efficiency, the reduction of power in proportion to the reduced fall, and the quantity of water accordingly reduced, together with the reduced speed, excludes them in the majority of low and varying falls.

The ideal turbines for low and varying falls are the "reaction" turbines. They are generally placed in a level with the tail water, or, if local conditions require them to be placed above tail water, connected with it by a suction tube. They run at a higher speed for the same fall, or the same diameter, than an "impulse" turbine, and their efficiency is not affected by the immersion in the tail water. The principal objection raised against "reaction" turbines in general

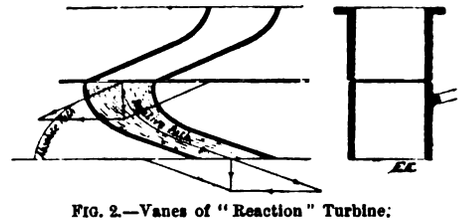

FIG. 2.—Vanes of "Reaction" Turbine.

is that their efficiency is greatly reduced when working at part gate. This is indeed the case with many of the reaction turbines known in this country, which give a very poor efficiency at part gate, especially at less than half gate. The continuity of flow of the water through the buckets is essential to a good efficiency. Only in a few reaction turbines is this condition fulfilled to such an extent that within very wide limits of the water supply the efficiency is not perceptibly reduced. The utilisation of a small and varying fall, with a varying quantity of water, is a very difficult problem for the water-power engineer. The turbine for a given power under a low fall is larger and runs slower than one of the same power under a higher fall; it is therefore heavier and more costly, and requires heavier gearing, entailing a greater loss of power through friction. A high speed is desirable, especially for driving dynamos, but attempts to increase the speed of the turbine by reducing its diameter may easily result in an inferior efficiency. The efficiency should be as high as possible in consideration of the greater cost of a water-power plant with a low fall, but the proportions within which such a fall and the quantity of water varies is mostly so great that it is almost impossible to obtain the highest efficiency when the water supply is diminished—*i.e.*, when a high efficiency is most

Digitized by Google

wanted. The maintenance of a constant power with a constant speed under variation of fall and quantity of water in large proportion can, if at all, only be attained by sacrificing some efficiency. The hydraulic losses must be reduced to a minimum by the most careful construction of the turbine in its essential parts, and it is needless to say that no standard size or type of turbine will fulfil all these conditions by simply consuming all the available water. Even the arrangement of the turbine-chamber is of influence on the results, and requires special attention. On a careful judgment of the local conditions depend the economy and the success of a plant. Unsatisfactory results in water-power plants are caused just as much, or oftener, by bad judgment of the local conditions than by the inferiority of the turbine.

In by far the most cases of low falls, incidental to flat countries, an abundance of water corresponds with a reduction of the fall. The power of a turbine calculated for the normal fall would be reduced, for the time, when an abundance of water reduces it, and, as a consequence, water would be wasted, while the power obtained is insufficient. These cases are, unfortunately, of frequent occurrence. On the other hand, if the turbine is constructed to give off the required power under the reduced fall, it must be partially closed for the diminished water supply with the normal fall, whereby the efficiency would be reduced just when it should be highest, if economy is at all the chief object of a turbine plant. The manner in which a high efficiency can be maintained for a diminished water supply is to subdivide the turbine into several compartments, each of which represents a complete turbine. This arrangement has been adopted by Fourneyron for his well-known outward-flow turbine, and in the modern Jonval turbine. The Fourneyron turbine is provided with a cylindrical gate, which is moved vertically, whereby each compartment is opened or closed. This type has been adopted for the large-power plant on the Niagara Falls, but on the European continent they are seldom used. Their efficiency is very good, but, owing to the narrowness of the buckets, they are easily choked. The Jonval turbine is a parallel-flow turbine, and is, for large variations of the fall and quantity of water, subdivided into two or more concentric compartments. A subdivision in this manner renders it possible to maintain not only the power, but also the speed, under a varying fall within very wide limits. The description of a Jonval turbine installation which I supplied for the Brantham Mills, near Manningtree, in Essex,

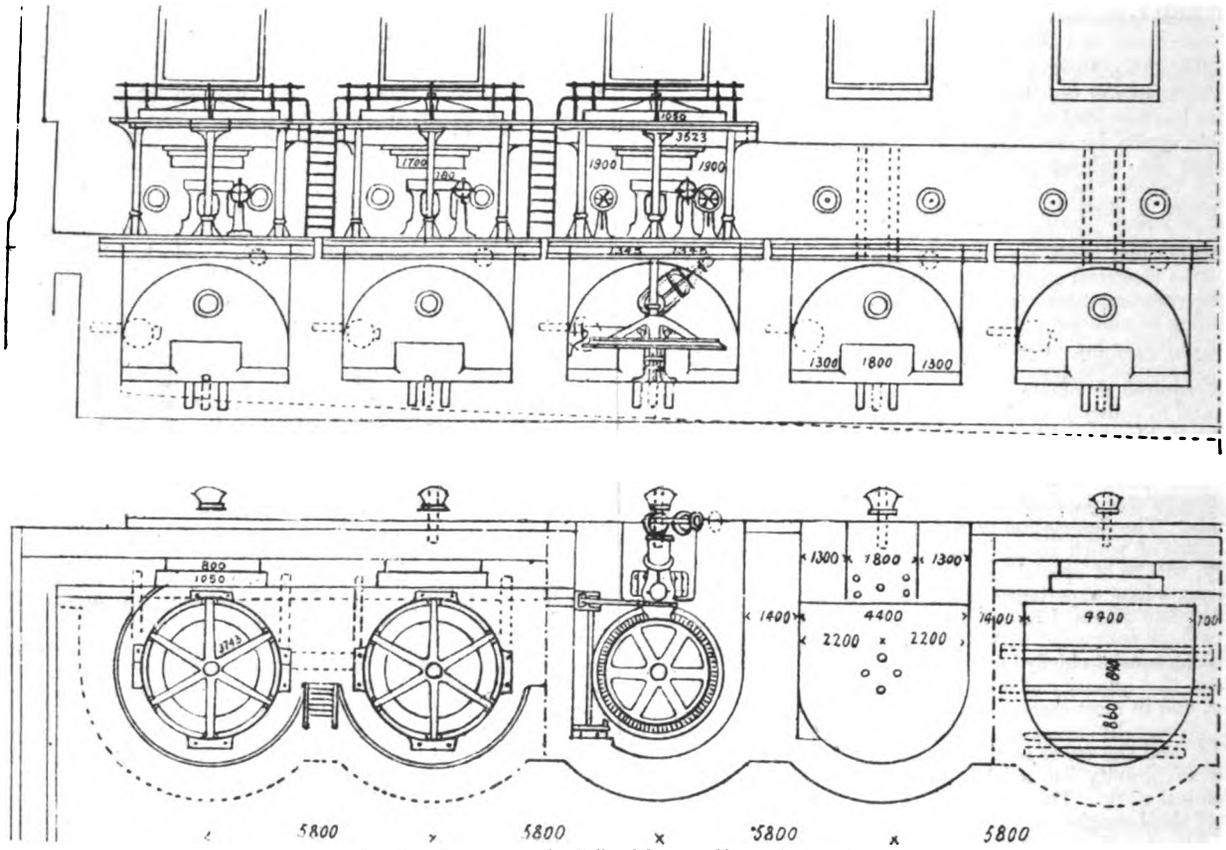

FIG. 3A.—Tu bines at the Falls of Foyers—Plan and Elevation.

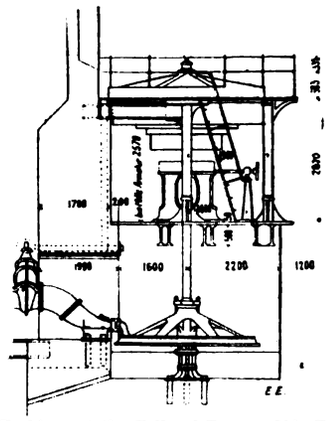

FIG. 3B.—Turbines at the Falls of Foyers—Side Elevation.

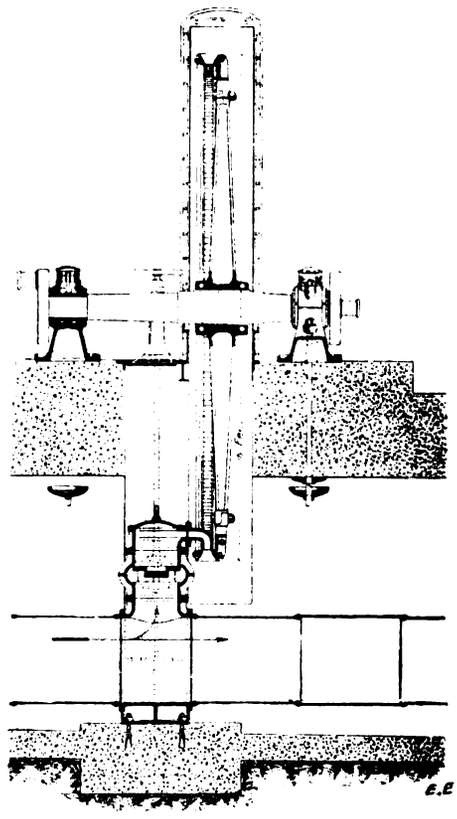

FIG. 4.—Turbines of the Chauxdefonds Waterworks, Switzerland.

will show that a very small and varying fall can be utilised with great advantage to obtain nearly a constant power. The local conditions and requirements are most remarkable and interesting. The power is used to drive a modern flour mill, in which the maintenance of a regular speed is of equally great importance as for driving an electrical plant. The River Stour is a tidal river, with a maximum fall at ebb tide of 4ft. 10in., while at high tide the fall is nil. The water is supplied partly by the river itself coming down from the hills of Cambridgeshire, and partly by the rising tide filling the river-bed above the mill for a considerable length. The power required is 40 actual horse-power, and it was stipulated that this power should be maintained down to a fall of 40in. On starting the turbine, it was shown, however, that it drove the mill at full capacity and at full speed under a fall reduced to 32in. The full power is available during 16 hours of each day, while during six further hours the power corresponding to a fall reduced down to about 1ft. is still utilised for driving a part of the machinery. Comparing the useful power obtained from this varying fall by the new turbine during 24 hours with that obtained by the undershot water-wheel previously working, it is nearly six times larger. The turbine consists of only two concentric rows of buckets; the inner one is provided with gates, which are opened or closed by hand-wheels, an automatic governor not being generally used in flour mills. The outer row of buckets is just large enough to give the full power required under the maximum fall. As the fall is decreasing by the rising tide the gates of the inner row of buckets are gradually opened to make up the power by an increased quantity of water, and the more water is passing through the buckets of the inner row the more it acts on a reduced mean diameter, thus maintaining also the proper speed without perceptible loss of efficiency. The outside diameter of this turbine is about 10ft., and it runs with 24 revolutions per minute. The power is transmitted from the turbine on to a horizontal main shaft by means of a pair of bevel wheels. This horizontal shaft is made to run at 75 revolutions, and is provided with a clutch, by means of which the turbine is connected with the steam-engine if the mill is required to work continuously. When the fall is reduced to more than 32in. the mill is, however, driven separately by the steam-engine, and the power of the turbine is used to drive the wheat-cleaning machinery, and eventually some pairs of millstones, which can work independent of the automatic roller-mill plant. When the fall is reduced to 15in. the power that is still obtained from this turbine is 7 h.p., the turbine naturally running slower, but still this power is quite sufficient to be profitably utilised.

(To be continued.)

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

BY DR. ARMSTRONG, F.R.S.

(Concluded from page 579)

Hence, in studying the manner in which chemical change is brought about, we are necessarily obliged to consider valency, comprehending under this term both the quantity and the quality of the "affinity" possessed by atoms. But, again, progress is trammelled by tradition and fashion—the habit of teaching dogmatically has affected our whole attitude towards such questions, our theories being not only unsatisfactory, but eminently narrow in their disregard of facts, especially apparent in our neglect of molecular compounds. Helmholtz, in his Faraday lecture, after dwelling on the conclusion that definite atomic charges of electricity are associated with the atoms of matter, said that he did not suppose that the existence of other molecular forces, working directly from atom to atom, was to be excluded. But is this the case? I venture to think that, had Helmholtz been a chemist, he would have felt compelled to admit that whatever be the nature of chemical affinity, the same forces are active throughout—that what is termed residual affinity is of the nature of ordinary affinity, and that the difference is in quantity rather than quality. To repeat what I said in 1888 in a note on valency especially as defined by Helmholtz (*Phil. Mag.*, 1888 [5], 25, 21), I do not hesitate to affirm that, from the chemical point of view, it is impossible to adopt the Helmholtz explanation of valency unless physicists are prepared to grant the possibility of the "division" of the unit charge. In the paper in question, to explain my meaning, I developed what may be termed a skewer hypothesis of valency, desiring to give a graphic expression of chemical facts and thus help those who are not chemists to appreciate our position. Representing unit valency or charge by a single line, I postulated this line as capable of passing through the atom, and the atom as moving with more or less of freedom on the line. The union of two atoms was pictured as an overlapping of the unit lines. On this hypothesis, in cases in which the atoms do not move out to the end of their lines on combining, free ends would exist, by the overlapping of which combination between molecules could be brought about; and if it be supposed that hydrogen and the metals alone move freely on their lines in order to give expression to the peculiar differences which apparently are manifest on contrasting the two classes of elements, the combination of a non-metal with a metal may be represented as involving the motion of the former alone out to the end of its line, leaving the line of the non-metal with a free end. In this manner expression may be given to what appears to be a fact—namely, that the non-metals condition the formation of molecular compounds.

What may be termed the *proper valency* of an atom—the number of atomic charges carried by, or of unit lines passing through, the atom—on this hypothesis, is a function of the atom alone, whilst its *residual valency* in a compound is a complex function depending also on the atoms with which it is in association. This is well illustrated in the case of nitrogen by the behaviour of the amines—in all of which the nitrogen clearly functions as a triad—towards haloïds and acids, the extent to which basic characters are manifest depending in an extraordinary degree on the nature of the radicles associated with the nitrogen atom. Assuming that the proper valency of nitrogen is three, the formation of ammonium compounds from amines may be represented as due to the overlapping of the free end of the halogen line and that of one of the nitrogen lines, and if, in a case like that of the chloranilines, it be supposed that the effect of weighting the C_6H_5 radicle by introducing chlorine is to reduce the amount of free end of the nitrogen line to which it is attached, expression is given to the fact that the amine becomes less and less basic, and more particularly that the salt becomes less and less stable as each fresh atom of chlorine is introduced, length of overlap being regarded as the measure of affinity.

It may be asked why, on this hypothesis, if the nitrogen atom carries three atomic charges—is penetrated by three lines—it does not combine with three molecules of acid. Of course, at present no definite answer can be given, but, bearing in mind that the conviction is becoming more and more clearly established that affinity has direction and that geometrical considerations come into play, it is at least conceivable that the direction of two of the lines is such that their free ends perhaps meet, or that they are so directed towards each other that other lines are prevented from overlapping them. The introduction of some such conception would seem to be necessary to explain the remarkable behaviour of compounds such as nitrous oxide and diazoimide, N_3H, the inertness of which is most surprising, whatever view to be taken of their constitution. Certainly, the difference between "unsaturated" nitrogen and "unsaturated" carbon which is manifest on contrasting these compounds with the olefines is most remarkable.

But it cannot be denied that, however possible it may be to "explain" the ammonium compounds on the assumption that nitrogen is but a triad, there are cases in which it is difficult to apply any such hypothesis as the above—one of the most striking being that afforded by the remarkable phenyliodonium compounds described by Hartmann and V. Meyer. It will scarcely be doubted by anyone, I imagine, that these and the equally remarkable iodoso-derivatives are not all to be regarded as proof that iodine is not merely a monad, but also a triad element; and yet it must not be forgotten that an iodine atom can combine with but a single hydrogen atom or methyl group, and that hydrogen and methyl are as yet the only trustworthy and, so to speak, legal standards by which the proper valency of an element can be measured. Even in such a case, therefore, a formula similar to that given to the ammonium compounds—viz., $C_6H_5{\cdot}I{\cdot}I{\cdot}C_6H_5$—cannot be put aside as absolutely out of the question; and if we bear in mind the peculiar character of the oxy-acids derived from the halogens, it is clear that much remains to be learnt of these elements. These acids are often quoted as arguments in favour of the view that the halogens are polyad elements, Mendeléeff having carried his poetic generalisations so far as to claim heptadicity for them; but even assuming that an oxide Cl_2O_7 exists, so long as we are unaware of its structure we must remain unable to judge of the valency of its elements, we are certainly as little justified in assuming that it contains heptad chlorine as we should be in concluding from the existence of a compound of the formula C_6H_6 that carbon is a monad. Valency is far too complex a function to be determined by a simple division method. It is not improbable that the oxy-acids in question are cycloïds.

The solubility of a substance such as triethylphenylammonium iodide in water, in which the amine and haloïd from which it is derived are so slightly soluble—and the fact that in the case of the ammonium salts of the chlorinated anilines above referred to hydrolysis of the salt takes place with increasing facility as the amine becomes less basic—may be referred to in further illustration of the difficulties to be overcome in formulating a consistent and sufficiently comprehensive theory of valency. On the hypothesis that such compounds are formed by the over-

* Presidential address delivered before the Chemical Society.

Digitized by Google

lapping of the free ends of the lines of affinity, the compound should remain saturated or externally inactive so long as there was any overlap; on the other hand, if the somewhat more elastic atomic charge hypothesis be adopted, and it be supposed that any portion of the charge remaining unneutralised might be active, at least the case of the chloranilines would meet with an explanation.

But all these are matters of pure speculation, and I should not venture to allude to them did I not feel that it is essential that now the amount of material at our disposal for discussion is so very large it is time that some attempt were made to arrange it in such a form that the results won by chemists can be laid open to inspection by physicists and others capable of taking such transcendental questions into consideration. The theory of types, and its logical outcome, the theory of bonds have contributed in a remarkable manner to the progress of our science; and to these geometrical conceptions have now been added which are leading to further important developments—but it can only be supposed that such theories will all prove eventually to be of provisional value, and that far less mechanical conceptions must prevail.

Underlying all modern chemical enquiries there is an obvious desire to determine the structure of molecules generally, as well as to correlate structure with function; and most important advances in these directions have already been made. Whatever view we may hold, it is only too clear, however, that the conventional treatment of the subject involves the disregard of much that is of the highest importance, especially is it, perhaps, too commonly forgotten that whilst the determination of valency involves the knowledge of the structure of the compounds of elements whose valency is sought, the determination of structure is itself based on an assumed knowledge of valency. We are not only being led to frame the conception that affinity has direction, but also that its strength largely depends on the direction in which it is exercised (as shown by the very different behaviour and stability of cycloïds of different dimensions), and it is more than probable, therefore, that ere long we may formulate a theory in which the somewhat mechanical bonds to which we have become accustomed will give place to a more comprehensive hypothesis.

Faraday, in the paragraph previously quoted, regards both the hydrogen and oxygen in water as possessed of "residual affinity," and in his day, no doubt, there was no reason to draw any marked distinction between the two classes of elements—the metallic and non-metallic. But there is much in the behaviour of the latter which seems to me suggestive of the conclusion that they are the mainly active, attracting elements, and those, in fact, which condition chemical change; I venture to think that this will more generally be admitted to be the case than it is at present when the facts are carefully considered. We have, it is true, long since abandoned the idea that only elements of opposite classes have considerable affinity for each other, but we are not yet advanced much beyond this, and have yet to recognise that the non-metals have very special mutual affinities.

It is in the play of these affinities more particularly that I am inclined to seek that conjoint influence to which I have frequently adverted by which electrolysis, and therefore change is, it seems to me, brought about. The force of the objection made to this explanation, that there are no appreciable reverse E.M.F.'s within an electrolyte, may easily be over-estimated. Adverting to what was said above with reference to the phenomena involved in charging a condenser, if any similar effect were produced in a fluid electrolyte—if any internal polarisation were set up—it would at once be discharged; and such polarisation would be imperceptible, just as in the case of the determination of conductivity by an alternating-current method. A considerable amount of work might, therefore, be done by the current unperceived, and the forces might well be enormous even within the liquid (compare Lodge, "British Association Report," 1890, 330). I am loth to believe also that the low values found for "ionic velocities" are in truth the velocities of the ions, and would prefer to regard them as but differences between values of which at present we have no conception.

A similar argument will apply in the case of osmotic pressure phenomena, and therefore generally in explanation of the regularities observed in the case of dilute solutions. To say that the osmotic pressure is due to the dissolved substance alone, appears to me to be but a useful figure of speech—in reality, the phenomena must be due to both solvent and dissolved substance. Although one attracts the other, however, the unions are probably but temporary, and the opportunities given for exchanges to take place are so infinitely numerous that the dissolved substance behaves practically as an almost perfect gas. From this point of view it is also not remarkable even that the pressure should have the same value as it would have if the substance were gasified, for, inasmuch as the molecules of the dissolved substance are kept apart by those of the solvent, they are practically in the gaseous condition.

As regards the superior effects produced by electrolytes, I would repeat what I said at Leeds in 1890 ("British Association Report"), p. 326, that, having been able by observations of electrical conductivity as well as by other methods to classify electrolytes in the order of their activity, we are now in a position to apply the correction required to discount the superior effects produced by such compounds in comparison with dielectrics. Why they are specially active, the future must decide. To me it seems that their activity is attributable to their special composition and structure—particularly to the presence in them of either oxygen or halogen in an eminently unsaturated condition, and possessed, therefore, of considerable residual affinity.

As regards semi-permeable membranes, as they have been called, I imagine we have yet much to learn in explanation of these. That the membranes through which liquid diffusion takes place cannot be mere sieves, there is hardly a doubt, otherwise it would scarcely happen that gases only diffuse through septa consisting of materials in which they are soluble; as illustrated by the diffusion of oxygen through caoutchouc and silver, of carbonic oxide through iron, and of hydrogen through platinum and palladium.

In the case of colloid membranes, through which so many crystalloïds pass, everything seems to depend on the peculiar relationship of water to such matters—a relationship which is so apparent in many physiological phenomena—and at the same time of water to crystalloïds.

The foregoing may be said to be an essay in advocacy of a theory of *association* in explanation of chemical change, as opposed to one of *dissociation*. The attempt has been made to show that such a theory is of universal application, whilst the dissociation hypothesis is apparently not only of limited application, but in some cases irreconcilable with the facts. It also involves assumptions which it is difficult for the chemist to grant: I allude particularly to the main article of faith in the dissociationists' creed that a certain very limited class of compounds—electrolytes—fall to pieces, as it were, more or less completely on entering into solution. As I have implied over and over again, such an assumption necessitates a profound distinction being made between electrolytes and other compound molecules generally which is not patent to the unprejudiced observer, and for which no motive or reason whatever can be assigned. It must not be forgotten that Clerk Maxwell was led by reasons of this very kind to remark that chemical combination is a process of a higher order of complexity than any purely electrical phenomenon.

I have sought also to make clear the great importance of the part played by "impurity" in Nature in conditioning chemical change—a part which seems to meet with an explanation from the association but not from the opposite point of view. The influence of impurities on properties has also been specially noted.

Lastly, the insight which the study of the electrical behaviour of substances generally promises to throw on almost all of the chief problems of chemistry has been briefly touched on.

I am only too conscious that my discussion of all these questions is not only incomplete, but very general and even vague in many places, language being sometimes used—as in quoting from Faraday—in a sense which may somewhat offend the purist; probably, however, the object I have in view will be clear even in these cases.

PHYSICAL EXPERIMENT IN RELATION TO ENGINEERING.*

BY DR. ALEXANDER BLACKIE WILLIAM KENNEDY, F.R.S., M.I.C.E.

(Concluded from page 577.)

The difference between physical and technical experiments may easily be illustrated by another example from the region of elasticity. The determination of the deflection of a beam, transversely loaded, as a physical experiment, would resolve itself into the test of the behaviour of a piece of homogeneous material, preferably of the simplest possible cross-section, probably rectangular. It would be a matter of importance to ensure that the material was exactly of a certain chemical nature, and that it was mechanically free even from the slightest defects; it would also have to be machined to certain exact dimensions. Even with every care, the almost unavoidable imperfections in the material, minute variations in uniformity of structure, and so on, would be very difficult to deal with and to allow for. As a technical experiment, on the other hand, the beam might consist of plate and angle-irons secured together by rivets, the whole forming a structure with absolutely no pretence to homegeneity, nor to absolute exactness of dimensions. Its rough surface would be carefully left intact, and not in any way machined, its riveted parts would be brought together as well as was reasonably possible with the appliances at the command of the engineer, but without any

* The "James Forrest" lecture delivered before the Institution of Civil Engineers, Session 1895-1896.

Digitized by Google

attempt to make a special fit between surfaces. In fact, the whole thing would be constructed in imitation of the way in which a riveted beam, such as is used as a girder, is usually made. The result obtained would obviously not be a general one applicable to steel as a material, or to beams as geometrical forms, because the data of the problem, even the dimensions of the beam itself, could not be determined with minute accuracy, nor would the actual final result be comparable in accuracy with the determination of the similar problem treated from the purely physical point of view. Hence, as the experimenter cannot for a moment pretend, and should not for a moment delude himself into supposing, that his results could be more accurate than his data, it is his first duty in this line of work to find out within what limits of accuracy his experiment can be carried out, and, when he has obtained his results, to state it only within these limits. Under these conditions the statement of a result in round figures is often much more accurate than its statement down to the last decimal place which appears in the arithmetic. I have heard it said by some of the students of the greatest of our physicists, Lord Kelvin, that this was a point upon which, even in a great deal of purely physical work, their master always insisted most strongly. But I am afraid that it must be admitted, as a weakness of much of our engineering experimentation, that its results are given in figures which are absolutely ludicrous as indicating the value of the quantities actually measured. In these matters, perhaps, our friends in America are even worse than we are, and those of us who have anything to do with steam-vessels or with steamship trials are perhaps the worst sinners. I suppose no physical problem could very well be much more complicated than that (I ought rather to say those) involved in the carrying out of a marine-engine trial at sea, especially when power and speed are both concerned. When it is considered that the final result depends on the accuracy of our knowledge of the dimension of the steam-engine itself, and of the steam-engine indicators, on the uniformity of elasticity and proper scale of the indicator springs, the accuracy with which the revolutions are observed, the accuracy of timing on the mile and of observing the distance at the same time, to say nothing of the assumption that the indicators themselves and their gear, unlike every other thing in the universe, are entirely devoid of hysteresis, it will be seen how entirely out of the question it is that the figures obtained, even for a single run in one direction, should admit of statement in, say, more than three figures. When to this is added the uncertainty of the method of averaging speed as between a number of runs under different conditions as to tide and wind, the matter becomes still more striking. Or, when coal and water are also to be measured, and the weighing or measuring of both, and the calibration of all the heavy apparatus used for the purpose, as well as the personal errors due to making observations of large quantities under awkward physical conditions, in a minimum of time and in the worst of atmospheres, are considered, the uselessness and indeed the absolute inaccuracy of extremely minute figures become absolutely glaring. It is sometimes useful, no doubt, under these conditions, to work out results to four significant figures for the sake of mere arithmetical checking; but no one who has had anything to do with the matter would suppose for a moment that more than three figures were of the least importance, and the statement of results of observations in five or six figures merely causes the enemy to scoff. Let me again say here that I am not suggesting, and I do not think, that an experiment of a technical nature is unscientific because its result is only capable of expression within 1 or 2 per cent., instead of within one or two hundredths per cent. I wish only to urge very strongly that in a really scientific spirit such an experiment must be undertaken only with a distinct recognition of its limitations, and of the limitations of accuracy of result such as I have roughly indicated.

But I must claim for technical experiment that it is truly scientific work if only it be conducted with full recognition of its conditions and limitations, and not as if it were a laboratory experiment badly done—a mistake which I fear is too often made. Let it be recognised first of all that our object is generally the determination of certain facts, or quantities, or ratios, which are to be found under certain very complex conditions. As I have elsewhere said, the duty of the engineer is to recognise these conditions and deliberately to include certain of them in his experiment. The physicist has to spend much thought and trouble on the modification of conditions which are disturbing elements in his work. All conditions which might modify his main result, or which might make it difficult for another experimenter to obtain precisely the same value for the quantity looked for, have to be either eliminated or evaluated. The conditions are his enemies, in fact. Otherwise with us, the conditions in general form part of our problem, and for many purposes the reduction of the experiment to its lowest terms, which is the object of the physicist, would not only be impossible, but would, if it could be done, make the result quite useless to us.

The determination of the efficiency of a steam-engine is, of course, a very common piece of work, and may serve as an illustration of the two different ways of approaching such a matter in connection with this question of conditions. From the physical point of view, I imagine it would be best to endeavour to reproduce the working of the much-abused Carnot cycle.* If that were absolutely successful it would merely give us a result which would agree with those which we can already calculate from the physical data which are in our possession, and this result would add nothing to our present knowledge, nor would it give any additional help to the designer of steam-engines.† But it would, if it could be carried out, be an experiment strictly physical, and following in the lines of, for instance, Joule's classical experiment on the mechanical equivalent of heat. The engineer, on the other hand, who has to work at the same problem, has to deal with it in the fashion in which it is now handled in so many engineering laboratories. He has to make himself an actual engine, in which the normal conditions of engine working—as to loss of heat by conduction, condensation, radiation, and so on—are, or can be, reproduced, and he has to make his experiments on this machine, and as nearly as possible under conditions resembling those under which engines normally do work. Then one by one certain of the conditions may be altered, so that some estimation may be made of the effect of each. So may be obtained figures as the result of *bonâ fide* technico-physical experiment, which are also in a form more or less directly applicable to engineering work.

I have just mentioned the variation of conditions one by one. This is hardly a matter which I need insist on. It is of great importance even in a physical experiment, where all the conditions are simplified to the last extent; but in a technical experiment, where the conditions themselves are very complex and often not easy to grasp, it is obviously vital. It is no doubt one of the great difficulties of all technical experiment to find out exactly what the conditions are, and it may in many cases need more experience and more care to determine and define the actual conditions than it does to carry out the measurements involved in the experiment. This is a matter which will be recognised by everyone who has had to do with work of this kind, but about which probably it is unnecessary to say more here. Bearing on it, however, is a matter which may fairly be mentioned—namely, the combining of the results of several technical experiments. This is often very tempting, but is always very difficult. A simple case is, for instance, the determination of the efficiency and of the economy of a steam-engine. A certain experiment may show a certain maximum efficiency; another experiment, on a more or less similar machine, but carried out at another time, may show a maximum economy. Naturally, there is a strong temptation to state both maxima as belonging to the machine tested. It is no doubt possible that they may do so; but on the other hand, without the most minute knowledge of the circumstances of the case, it is quite unsafe to assume that they do, and in this respect the difference between the general character of purely physical work and the special chaarcter of technical experiment comes into clear relief.

In fact, it is much more difficult to handle rightly the results of engineering experiment when they have been determined than those of pure physics. It is by no means always, or obviously, easy to apply these last—at least, one has known very ludicrous mistakes to occur through their misapplication. For instance, I have seen elaborate calculations based on the determination of the weight of steam used by an engine from the pressures shown by an indicator card and the measured dimensions of the engine; and quite recently I was confronted with certain supposed phenomena, which rested entirely on the assumption that a vessel of certain dimensions actually received from a steam-pipe suddenly opened to it only the weight of steam corresponding to its volume and the pressure shown by a gauge! In both cases the troublesome phenomena of condensation were entirely left out of account, and the result of a purely physical determination was applied to a technical problem with very disastrous results. But it is infinitely more difficult often to interpret and to apply the results of our own experiments. For instance, let it be found that one boiler, engine, and dynamo together require the consumption of so many pounds of coal per electrical unit; how much coal per

* I need hardly say that I do not for a moment suggest that any physicist would wish to obtain experimentally a result for which he has already given us all the constants, and which we can, therefore, completely obtain by calculation based on physical results already before us.

† I do not wish here to be understood in the least as sharing that great objection to the Carnot cycle which I know fills the breasts of some of my friends. It appears to me that it would be just as reasonable to object to the asymptote of a hyperbola or to the line at infinity! We require these limiting cases and should get on very badly without them, and I am not inclined to say that they are useless—indeed, I think they are extremely useful—although I am perfectly conscious that they represent a state of affairs which is technically, and even physically, unattainable.

Digitized by Google

unit will another boiler, engine, and dynamo require? Put baldly in this form the question sounds ridiculous. But after all, is it any more absurd than our constant endeavour—that is, before the days of the present development of engineering experiment—to arrive at similar comparative conclusions from the doubtless unimpeachable figures of an engineering pocket-book? I am sure there must be many of us who can still recollect how painfully we endeavoured to make the statements of Molesworth furnish us with an answer to our own problems, and how entirely we failed to get things to fit in. I do not suggest that the fault lay with the pocket-book. The fault lay in the endeavour to correlate figures and results which in no way belonged to each other, which represented the result of experiments made under conditions quite unknown to us, but certainly varying from each other, and no less from the conditions (possibly also unknown to us) of the problem we actually were trying to work out. I dare say that many of us who have been hungry and thirsty for facts and figures during most of our lives remember very well the joy with which, at a certain stage, we put down in our note-books any kind of experimental results of which we could hear, or of which we could obtain possession by any means, whether they related to steam-engine trials or to girder tests, or to the discharge over weirs. I do not say to dynamo trials, because there were no dynamos in those days! And I am sure that all of us must have suffered pain and disappointment later on when we found how extremely difficult it was to make any use of the much-valued figures that filled our pages; they would never, somehow or other, seem to tell us just what we wanted—there was always something about them which eluded us, one particular matter of vital importance in the data or in the result of which we had no memorandum. The fact is, that it is always difficult to apply accurately the results of experiments made by others, however carefully made and however accurately described. To realise this, even in reference to purely physical work, one need only see how many pages in the *Philosophical Transactions* are sometimes necessary to describe the methods and precautions involved in a determination which has not one-tenth the complexity of such matters as we are compelled constantly to try to measure.

To anyone who wishes to realise to the full the difficulty of dealing with, or applying the very simplest kind of experimental result, I recommend the maddening task, so often lightly spoken of by those who have not tried it, of calibrating indicator springs, and then trying to apply the results to the correction of the corresponding indicator diagrams.

The fact is that no one can usefully apply physical results who has not himself studied the methods by which these results are obtained, either by the royal road of work in a physical or technical laboratory, or by the hard and up-hill method of self-education in the making of technical experiment, without the advantage of the preliminary training which I have mentioned earlier, and hence the importance of the knowledge of how to make accurate observations, which I have insisted upon as a thing quite apart from the knowledge of the actual figures to be obtained by such observations. It would, perhaps, be cruel to say that no one can usefully apply physical results who had not studied the methods by which they are obtained, were it not that nowadays the possibility of such study is open to everybody. One may therefore state the truth in this matter without the fear of making anyone unhappy. I do not know whether I should be far wrong in suggesting that a certain amount, perhaps a great deal, of the very rapid improvement which has taken place in late years in engineering practice in respect to efficiency in the working of machinery, economy in the production of energy, and economy also in the use of material, has been due, directly or indirectly, or both, to the growth of the habit and knowledge of experiment among the present generation of engineers. No one who is familiar with the progress in such matters as I have this evening dealt with, during the last 20 years, and has noted the extraordinary development which has taken place, can fail to be struck with it. No doubt a considerable part of this development has been due to the better education generally of engineers, and particularly to the great extension of engineering literature, in which undoubtedly the engineering newspapers have played a most honourable and important part. But these general causes in themselves would not, I believe, have been sufficient if it had not been for the contemporaneous development of what I may venture to call experimental training, accompanied by a demand on all hands from inventors, manufacturers, and even from the public, for reasonably exact numerical statements in relation to everything which can be measured, instead of the vague generalities which used to pass muster as critical examination of the advantages and disadvantages of any new proposals.

I hope I need not say here that I quite recognise that an engineer's life is not made of experimentation, and that the work of doing is even higher than that of measuring, at least from our point of view. But in dealing with my subject of to-night I am, of course, bound to take up and emphasise this aspect of engineering work. I hope that it may be considered that I have been able to justify my choice of a subject which at first might appear so limited, but which, in reality, I believe so important as that to which I have addressed myself this evening the relation of physical experiment to engineering.

THE PHYSICAL SOCIETY.

At the ordinary meeting of this society on May 22 Prof. Ayrton (vice-president) in the chair, **Mr. R. Appleyard** read a paper on "**Dielectrics.**" The author has particularly investigated the effect of temperature on the dielectric resistance, and has employed for this purpose condensers insulated with mica and paraffined paper. In order to eliminate some of the effects of surface leakage, Price's guard ring arrangement was made use of in all the experiments. The author finds that the capacity of a paraffin condenser varies irregularly with the temperature, but that to within the accuracy attainable with his instruments (1 per cent.) the capacity of a mica condenser is constant between 33deg. F. and 110deg. F. If the resistance of paraffin at a temperature t is represented by $R_t = R\alpha^t$, the mean value for log. and deduced from all the author's measurements being $\bar{1}\cdot 96344$. Experiments made with a parallel plate condenser, with paraffin as the dielectric, show that when the temperature reaches within about 20deg. of the melting point the resistance rapidly falls. When melting commences there is a rapid drop, but while melting is in progress the resistance remains constant.

Prof. Ayrton said he could bear witness to the extreme value of Mr. Price's device, as it completely did away with the necessity for the extreme care previously required to prevent errors due to surface leakage. He regretted that he had not had an opportunity of comparing the author's numbers with some obtained some years ago by Prof. Perry and himself.

A paper by **Prof. Viriamu Jones** on "**The Magnetic Field due to an Elliptical Current at a Point in the Plane of the Ellipse and Within It,**" was taken as read.

Prof. Silvanus Thompson said that this paper was of interest, not only on account of the application which others might make of the author's method, but also in that the correction when applied to Prof. Jones's results brought the international ohm more nearly into accord with the true ohm.

Mr. J. J. Walker said he considered that the paper was more suited to the Mathematical Society. The integration, which the author reduced to elliptic integrals, might be more easily performed by another method.

Prof. Ayrton said that Prof. Jones's value for the true ohm was now 106·302cm. of mercury.

Mr. Campbell read a paper on "**New Instruments for the Direct Measurement of the Frequency of Alternating or Pulsating Electric Currents.**" The author employs two arrangements, in one of which a steel wire, the tension on which is variable, and the other a steel spring, of variable length, clamped at one end, are acted upon by an electromagnet through which the periodic current is passed. The tension or length, as the case may be, is varied till a maximum resonance is obtained, a small contact-piece being employed to detect when this occurs. The instrument exhibited was capable of measuring the frequency of periodic currents of from 40 to 150 double vibrations per second.

Mr. Watson said he thought that in the case of the steel spring there would be a considerable temperature correction, and he suggested a method by which this might be compensated.

Mr. Blakesley asked if the author had found that the spring became magnetised, and thus gave the octave.

Mr. Carter asked whether elastic fatigue influenced the results, and said that a synchronous motor and a speed indicator could be used to measure the frequency.

Prof. Silvanus Thompson suggested that it might be better to employ a polarised apparatus since to avoid the impression of forced vibrations on the spring it was better, as was done in the case of tuning-forks, to make it massive. It had been found in other cases, such as in Hughes's telegraph, and the telephone, that better results were obtained with polarised apparatus. He (Prof. Thompson) had used a telephone, placed anywhere near a magnet traversed by the periodic current, together with a tuning-fork, which gave beats with the note produced by the telephone, to measure frequencies. The variations in frequency ordinarily met with in practice were much greater than it was generally suspected.

Mr. Blakesley said he considered that the advantage of the author's instrument over a telephone and tuning-fork was that it was continuously variable over a large range.

Mr. Enright asked if the author had been troubled by the spring or wire breaking into overtones. In some experiments in which rather long wires were used, he had been troubled in this way.

Prof. Ayrton said that he did not think that it was possible to get the wire or spring to respond to the octave unless the alternating current contained a component of the frequency of the octave. In fact, he had himself used such a stretched string as a wave analyser. He had used a telephone to prove that the note given by a hissing alternate-current arc corresponded in frequency to that of the current. In the instrument used by Prof. Perry and himself a polarised arrangement was always employed, since the alternating current was passed either through a wire in a constant magnetic field, or through an electromagnet which acted on a wire through which a constant current was passed.

The **Author**, in his reply, said that the instrument responded, though feebly, to the octave, and this response might be made use of to check the accuracy of the scale.

The society then adjourned till June 12.

LEGAL INTELLIGENCE.

THE BRUSH COMPANY AND THE SHOREDITCH VESTRY.

An action was commenced in the High Court of Chancery on May 21 by the County of London and Brush Provincial Electric Lighting Company, Limited, to restrain the Vestry of St. Leonard, Shoreditch, from laying down electric lines beyond the area within which the Vestry are authorised to supply energy under the Shoreditch Electric Lighting Order, 1892.

It appeared from an affidavit that the Vestry commenced on May 21 to excavate a trench for the purpose of laying down electric lines within the parish of St. Luke, Middlesex, a district for which the County of London Company have a provisional order.

On the application of Lord Robert Cecil (instructed by Mr. Sydney Morse), Mr. Justice Henn Collins gave the Company leave to serve summons and writ for June 2, and granted an injunction in the meantime.

COMPANIES' MEETINGS AND REPORTS.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

A meeting of the creditors and contributories of this Company was held on Tuesday at 73, Lombard-street, E.C., to receive the account of the liquidator, Mr. C. Fitch Kemp, in reference to the winding-up of the Company and to consider an offer which has been received by the liquidator from Lloyds' Bank, the second debenture holders having an unsatisfied claim of over £3,000 on the second debenture issue, for the purchase of the outstanding assets of the Company and the closing of the liquidation. Lloyds' offer was to pay £1,300 in cash and discharge the balance of the second debenture debt in return for all the outstanding assets of the Company—that is, a balance of £127 on uncalled capital; a claim (disputed) for £3,000 on the New Zealand Electric Syndicate; and 2,335 £10 shares in that syndicate. The liquidator stated in his report that the cash would be nearly absorbed in discharging a debt of £1,000 and interest, and the balance would be accepted in discharge of the costs of the liquidation, although it would not be sufficient to cover them on any ordinary scale. Failing the acceptance of the offer, it would be impracticable to pay in full the second debentures of the Company unless some substantial recovery were made (which the liquidator considered perfectly hopeless) on account of the debt for uncalled capital due from Miles and Co., Limited, who were in liquidation. While as to the claim on the New Zealand Electrical Syndicate, the assets of that company were situated in New Zealand, and no tangible amount could be recovered, if at all, except at the risk of costly and protracted proceedings in New Zealand, and probably in the English Courts also, the expense of which would have to be provided by the creditors and contributories of the Company. Having regard to his knowledge of the position of the syndicate, the liquidator considered that he would be utterly unjustified in recommending creditors and contributories of this Company to make voluntary contributions for such a purpose.

Mr. Fitch Kemp (the liquidator), who presided, remarked that at present he was under a liability to Lloyds' Bank, and his solicitor and himself were without any costs. He had power to conclude the arrangement indicated above, but as the result was so unsatisfactory, he would prefer not to do so without the sanction of the meeting.

A considerable amount of conversation followed, in which **Major Cotton** and **Mr. Morgan** took part, on the question whether there might not be a possibility of recovering something from the debtors of the Company. Finally, **Major Cotton** suggested that, say, £1,000 (nominal) of the shares in the syndicate should be retained by the liquidator with the view that if at any future time they should become of any value the sum realised might be used in payment of the trade creditors of the Company The case of the shareholders was admitted to be hopeless. It did not, however, appear that Lloyds' Bank would be willing to modify the terms of their offer in this direction, nor did it seem that the whole of the money, if any were ever obtained, would be available for the purpose indicated.

Ultimately, on the motion of **Major Cotton**, seconded by **Mr. Morgan**, the resolution authorising the acceptance of the offer of Lloyd's Bank was carried unanimously.

WEST COAST OF AMERICA TELEGRAPH COMPANY, LIMITED.

The report of this Company for the year ending December 31 states that the gross income as shown in the revenue account was £32 930, as against £21,753 in 1894. The traffic receipts were adversely affected by the stagnation in the nitrate industry and other local causes, but, owing to a readjustment of the proportions of the international traffic receipts for the year, the income was sufficient to pay the expenses and the interest on the debentures. The total expenses were £20,930, against £20 154. The repairing steamer "Retriever" has been fitted with a new steel main boiler, the cost of which (£1,978) has been charged to the reserve fund. The steamer is now considered to be in first-class condition, and, outside of accidents, fit for service for the next 12 years. The cables and land lines are maintained in good working order. The general meeting will take place to-day (Friday).

BOURNEMOUTH AND DISTRICT ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: Aymor H. Sanderson, A.I.E E., chairman; J. Atkinson Hosker, M.R.C.S.; R Percy Sellon M.I E E. Consulting engineer: A. J. Lawson, M.I.E.E. Managing engineer: H. M. Sayers, A I E.E Secretary: H B. Renwick.

Report of the directors (with abstract of accounts) to be presented to the shareholders of the Company at the fifth annual general meeting of the Company to be held at the registered offices, Verulam House, Yelverton-road, Bournemouth, on Tuesday, June 2, 1896, at 3.30 p.m :

The capital account shows an expenditure during the year of £20,845. 8s. 7d., chiefly upon buildings, machinery, and mains, the funds for which were obtained by loan from the County of London and Brush Provincial Electric Lighting Company, Limited. The revenue account, notwithstanding a reduction in the maximum price of current from 8d. to 7d. per unit, which was made in the month of April, 1895, shows a total income of £7,431. 3s. 10d., being an increase of £458. 13s. 8d. over that of 1894; and an expenditure of £5,272. 12s. 7d., being a reduction on the previous year's figure of £57. 15s. 10d. The gross profit on the year's working thus amounts to £2,158. 11s. 3d., as against £1,642 1s. 9d. in 1894, but owing to increased charges for interest on sums borrowed for capital expenditure there remains a debit balance of £237. 15s. 9d. to be carried forward. The connections to the Company's mains on December 31 last were equivalent to 20,978 lamps of 8 c.p., the increase for the year being equivalent to 1,798 lamps, or 9½ per cent. upon the number connected on December 31, 1894 The number of Board of Trade units of current sold during the year amounted to 243,816, as against 214,374 in 1894, an increase of nearly 14 per cent., whilst the total cost per unit was reduced from 5·91d. to 5 19d. The generating station has been rebuilt and rearranged during the past financial year, and with the advantage of the many improvements which have been adopted the directors believe that a considerable further reduction in cost of generation during the current year may be anticipated. The retiring director is Mr. J. A. Hosker, who, being eligible, offers himself for re-election. Mr. R. H. Marsh, the auditor, also retires, and offers himself for re election.

REVENUE ACCOUNT, YEAR ENDED DEC. 31, 1895.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Mako (Hungary).—The municipal authorities of Makö in Hungary are desirous of receiving proposals for the electric lighting of the town.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadtrath, Prague.

London, S.E.—Tenders are required for complete installation of electric lighting. For particulars apply by letter to Mr. H. Freeman, 44, Knatchbull-road, Camberwell, S.E.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31.

Santiago de Chile.—The Telegraphic Department of the Chilian Government will receive tenders up to June 6 for the supply of 5,000 glass jars for Leclanché cells and about 3½ tons of sal-ammoniac (pure).

Coblentz.—Tenders are wanted by 30th inst. for the annual supply of 10,000 to 13,000 wooden telegraph poles for four years. Particulars from the offices of the Konigl. Ober-Postdirection, Coblentz for 30pfg. (3d.).

Brussels.—Tenders will be received shortly (the exact date is not yet announced) at the Brussels Bourse for the material and work necessary to start an electric lighting installation at the fifth section of the central locomotive construction works at Malines.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Dresden.—The Telegraph Department of the Saxon State Railways want tenders by June 10 for about 50 tons of galvanised iron wire (4 millimetres) and 10 tons of smaller sizes; also 3,700 glass jars (various) for battery cells, and 10,000 porcelain insulators large size and 2,000 of smaller sizes as well as 7 500 zincs for Meidinger and 1,000 for Leclanché cells. Particulars from Die Königl. Magazin-Verwaltung, Dresden-Friedrichstadt.

Bucharest.—The Municipal Authorities of Bucharest ask for further tenders up to June 24 for lighting the suburbs and environs "on a system without (underground) pipes more suitable than those that have been already offered." It is desired to replace 3,265 petroleum lamps, and the contract will be for five years. Communications should be sent to the Mairie at Bucharest.

Spandau.—Tenders are wanted at the Royal Small-Arms Factory for 900 incandescent electric lamps by July 17 and for 27,300 sets of arc-lamp carbons by June 12. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21), Spandau.

Grimsby.—Tenders are required by the Urban Sanitary Authority for lighting of the public streets of the borough for one year. Forms of tender, copy of specifications, and any further information may be obtained on application to Mr. Marshall Petrie, borough surveyor, Town Hall. Tenders, sealed and endorsed "Tender for Street Lighting," to be delivered at the Town Clerk's Offices, West St. Mary's-gate, by 5 p.m. on June 5.

Bradford.—The Corporation invite tenders for the works required in the installation of electric lighting at Cliffe-road destructor works. Specification, with form of tender, may be obtained on application to Mr. W. T. McGowen, town clerk, Town Hall, Bradford. Sealed tenders, endorsed "Tender, Electric Lighting at Cliffe-road Destructor Works," to be delivered at the Town Clerk's Office by June 2. An assurance will be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages.

York.—The North-Eastern Railway Company require tenders for the following articles during six months ended December 31, delivered carriage paid at the telegraph stores at York: (1) telegraph apparatus; (2) telegraph wires and line stores. Payment for each month's delivery will be made at the end of three clear months, or in cash less 2½ per cent. discount. Forms of tender may be obtained on application to Mr. Greaves, Telegraph Department, York, and tenders must be sent to the Secretary, York, sealed, and marked "Tender for Telegraph Stores," by noon on June 8.

Croydon.—The Corporation require tenders for the erection of a chimney shaft for the electric lighting station now being built in Factory-lane, Croydon, in accordance with drawings prepared by Prof. Kennedy, Old Queen-street, Westminster. The drawings and specification can be seen at the Borough Engineer's Office, 8, Katharine-street, Croydon, where also bills of quantities and form of tender can be obtained on payment of a deposit of £2. 2s., which will be returned to every person sending in a bona fide tender. Tenders to be sent to Mr. E. Mawdesley, town clerk, Municipal Offices, 8, Park-street, Croydon, by 11 a.m. on June 8.

Glasgow.—Tenders are invited by the Caledonian Railway Company for the supply of telegraph and electric appliances, etc., for 12 months from August 1, 1896. Specifications and forms of tender and any other necessary information may be obtained on and after June 1 from Mr. Jas. Lorimer, superintendent of stores, Caledonian Railway, Charles-street, St. Rollox, Glasgow. Patterns may be inspected on and after June 1 from 9 a.m. till 5 p.m. at the Company's Stores, Charles-street, St. Rollox (Saturdays 9 a.m. till 1 p.m.). Tenders, endorsed "Tender for Stores," to be lodged with Mr. J. Blackburn, secretary, 302, Buchanan-street, Glasgow, by June 15.

Leeds.—The City Council invite tenders for an electrical installation sufficient for the working by the overhead system of haulage, a double track of tramway seven miles long. The work will be divided into the following contracts: (1) poles for supporting trolley wire; (2) underground conduits and conductors; (3) trolley wire and attachments; (4) motorcars; (5) accumulators and switches; (6) steam-engines; (7) dynamos, switchboards, and accessories. Tenders, endorsed with the number of the contract, must be sent in, addressed to the Town Clerk, Town Hall, Leeds, by June 20. Particulars, plans, forms of tender may be had (on payment of a deposit of £2. 2s. for each contract, which will be returned on receipt of a bona fide tender) from the City Engineer, Municipal Buildings, Leeds; or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, S.W.

RESULTS OF TENDERS.

Castor.—For providing a lightning conductor to the spire of the parish church of Castor, near Peterborough, the tender of Mr. Campbell, Milton-street, Peterborough, was accepted.

Paris.—The contract for the electric lighting of the Hospice de Brevannes (Seine-et-Oise) has been allotted to Messrs. Durand and Guigné, rue de Trevise, Paris, at 6·6 per cent. abatement on the official estimate.

Coventry.—For the supply and erection of the following plant: (Section A) boiler-house plant—boilers and fittings, mechanical stokers and economiser, feed pump, etc; (Section B) engine-house plant—steam-engine, alternator, oil filter, fittings, etc., steam, exhaust, feed, blow-off, sundry pipes, valves, etc., for the Electric Lighting Committee, the tender of Messrs. J. Fowler and Co., Leeds, £4,198, was accepted.

Wakefield.—The Council have accepted the following tenders for the proposed electric lighting works: brick, stone, excavating, slaters', carpenters', joiners', and plasterers' work, Messrs. Holme and King, Cross Hall-street, Liverpool, £7,887. 15s. 6d.; plumbers' work, Mr. Fred Mosley, Wakefield, £190. 18s.; smiths' and iron-founders' work, Mr. C. Bailey, Savile Town, Dewsbury; painting, Messrs. Charles Turner and Sons, Wakefield; glaziers' work, Mr. John Scaife, Warrengate, Wakefield. The fair contracts clauses were adopted in regard to sub-letting, working hours, and rate of wage, etc.

Hackney.—Mr. S. J. Ross has been appointed engineer and electrician at the baths, at a salary of £156 per annum.

Digitized by Google

BUSINESS NOTES.

Aberdeen.—The Plans Committee of the Town Council have sanctioned plans of an extension to the electric lighting station.

Lancaster.—At the meeting of the Town Council it was reported that there was a loss of £539 on the electricity works during the year.

Burnham.—We are informed that Messrs. Donnieson and Co. are still endeavouring to get sufficient support to introduce the electric light into the town.

Chester.—The County Council have decided to grant a sum of £3,000 for the purpose of installing the electric light into the existing asylum buildings at Upton.

Electric Safety Lamps.—We understand that Mr. Sydney F. Walker, of the Cardiff Electrical Works, will shortly bring out an electric safety lamp on entirely new lines.

West African Telegraph Company. — The directors have declared a further dividend of 6s. per share, making a total distribution of 4 per cent. for the year 1895

Barrow.—There is a proposal to construct a light railway from Backbarrow, through Finsthwaite, the Sawreys, and Esthwaite to Hawkshead, and electricity is suggested as the motive power.

Dresden.—The Elektricitätswerke Aktiengesellschaft Kummer und Co. has paid an 8 per cent. dividend, and is about to increase its capital account from one million to 2½ million marks (£125,000).

Address.—Mr. G. A. Steinthal has opened an establishment for electrical contracts and supplies at 7, Brazennose-street, Manchester, the management of which has been entrusted to Mr. W. P. Steinthal, B.Sc.

Folkestone.—The Corporation have decided to refer the whole of the correspondence, agreements, etc., on the subject of electric lighting to an expert of good position to advise on all the various points and to report thereon.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending May 24 amounted to £1,178, as compared with £1,135 in the corresponding week of the previous year, being an increase of £43.

Belfast.—At the meeting of the Electric Committee the usual report was presented by the engineer, and he was authorised to attend the annual meeting of the Municipal Electrical Association in London on June 10, 11, and 12.

Aberdeen.—The Streets and Roads Committee have decided to charge the Telephone Company a rent of 10s. per pole per annum, the Corporation, in addition, to be allowed 25 per cent. reduction on all their telephonic connections.

London Extensions.—Rapid progress has been made with the laying of the mains and the erection of the columns in the West-end. In Regent-street several of the lamp columns are already in position in the centre of the roadway.

York.—A meeting of representatives of the various parishes in the city has been held in reference to the proposed electric lighting scheme, and it was decided to call a mass meeting of ratepayers at an early date to consider the question.

Telephone between London and Nice.—The *Petite République* states that two engineers have made arrangements with the French Government for the establishment at an early date of telephonic communication between London and Nice.

Printing Telegraph Recorder Company, Limited. — This Company has been registered, with a capital of £10,100, to carry on the business of manufacturers of type printing and other telegraph recorders, as telegraph engineers, etc.

Removal.—Messrs. Eugen Conrady and Co., electrical and mechanical engineers, have removed from Keighley to London, where they will continue to manufacture their specialities at the new works, 35, Charles-street, Hatton-garden, E.C.

Dublin.—We understand that the public have patronised this line extensively since its opening for regular traffic. Over 50,000 passengers were carried on the first day, and the number carried up to the present has reached the enormous total of 200,000.

Burnley.—The Electric Lighting Sub-Committee have decided to recommend the Council to authorise the laying of electric cables along Church-street and Ormerod-road, and of sufficient capacity to supply 2,000 lights, at an estimated cost of about £1,000.

Lahore.—The Municipal Committee are considering the question of lighting the streets by electricity. The city and station have been surveyed, and it is hoped a company will shortly be formed who will take up the work as soon as the Local Government can secure the necessary legislation.

The Electric Wiring Question.—The paper which was read on this subject by Mr. F. Bathurst at the meeting of the Institution of Electrical Engineers has been reprinted, with the reply to the discussion, by the General Electric Company, Limited, from whom copies can be obtained on application.

Central American International Exhibition.—With regard to this exhibition, which is to be held at Guatemala next year, the British Consul points out that it might be made a means of introducing more British products into the country. There is at present a great demand for electric plant, etc.

Liverpool.—The town clerk having reported to the Finance Committee that the Bill for the purchase by the Corporation of the Liverpool Electric Supply Company's undertaking would receive the Royal assent, arrangements are being made to complete the purchase and transfer on July 1 next.

Coventry.—At the meeting of the City Council the Electric Light Committee tendered a statement for the quarter ending March 31. The electricity supplied during the quarter amounted to 10 642 units, the rental to £284. 1s., and the mileage of the mains is—high tension, 2 miles 77 yards, low tension, 2 miles 332 yards.

Birmingham.—The project for the purchase of the undertaking of the Birmingham Central Tramways by a new company, with enlarged capital, has given rise to some discussion as to whether on the leases of the lines expiring the City Council should not work them itself, as is done by Corporations at Glasgow, Leeds, and Huddersfield.

City and South London Railway.—The returns for the week ended May 24 were £893, compared with £884 for the corresponding period of last year, being an increase of £9. The total receipts for the half-year terminating as above were £19 693, compared with £19,604 in the same period of the preceding year, being an increase of £89.

Direct Electric Generator (Foreign Rights) Syndicate, Limited.—This Company has been registered to carry on the businesses of manufacturers of and dealers in carbon plates, slabs, rings, crucibles, rollers, bars, rods, pipes, or any other articles requisite for electrical or other purposes, also as electrical engineers and electricians, suppliers of electricity, etc.

Carbon (Foreign Patents) Syndicate, Limited.—This Company has been registered to carry on in all or any of their respective branches the businesses of manufacturers of and dealers in carbon plates, slabs, rings, crucibles, rollers, bars, rods, pipes, and other articles for electrical and other purposes, and as electrical engineers and electricians, suppliers of electricity, etc.

Richmond (Surrey).—Councillor Hilditch, J.P., is agitating in favour of working the Kew tramways by electricity, and he writes to the local Press that he has seen plans of three new systems that dispense with the "objectionable overhead wires." He alludes to the Westinghouse Company's system, the Siemens conduit system, and another subterranean trolley system working in an American city.

Douglas.—At the meeting of the Town Council a letter was read from the tramway company stating that if the Council would have Prospect-hill widened in readiness for laying the rails by June 2 the company would probably complete the upper Douglas cable tramway by June 1. The Council decided that while they would expedite the matter they would not undertake to have Prospect-hill ready by June 2.

Chelmsford.—At a special private meeting of the Town Council it was decided that the question of purchasing the town lighting from Messrs. Crompton and Co. for £34,828—the price asked—should stand over for the present. At the meeting of the Guardians the application of Mr. Clark, of East Hanningfield, to be allowed to put down some posts for carrying electric lighting wires was not granted because it was for private lighting.

The Universal Engine.—In consequence of the demand for the Raworth Universal steam-engine, the directors of the Brush Electrical Engineering Company have decided to extend their works at Loughborough. The new tool shop, which will be devoted entirely to the engine trade, is to be 160ft. long by 48ft. wide. Building operations have already commenced, and it is hoped that danger of delay in the execution of orders may be averted.

Bath —The Urban Sanitary Authority have decided to apply to the Local Government Board for power to borrow £45,000 for electric lighting purposes, made up as follows: sum to be paid to the company as by Prof. Kennedy's valuation, and for land, £24 533; expenses incurred in obtaining the provisional order, etc., about £967; additional capital required as estimated by Mr. Hammond, £14,500; for further extension of main, £5,000—total, £45,000.

Bradford.—At a joint meeting of the representatives of the Iron Moulders and United Patternmakers, the question of fair contracts was discussed in connection with the extension of the Corporation electricity works. Evidence was given that the contract for the ironwork for the extension of the works had been let to a firm who do not pay the minimum rate of wages of the town, in violation of the fair contracts clause. The society offered a vigorous protest against such firms being allowed to do Corporation work.

Liverpool Electric Supply Company, Limited.—The directors of this Company have issued a circular to the shareholders stating that the Act of Parliament confirming the sale of the undertaking to the Corporation of Liverpool has now received the Royal assent, and that the completion of the purchase will take place on July 1 next. On that date the Company will post to the shareholders cheques for £8. 5s. per share, being £8. 2s. in respect of capital and 3s. for dividend at the rate of 6 per cent. from January 1 to July 1.

Dover.—The Town Council have decided to send a deputation to towns where the overhead electric system of trams is in operation. It is estimated that to give a 10 minutes' service from the pier to Pencester-road, a 30 minutes' service to Maxton, and a 15 minutes' service to Buckland, they would require four motorcars and two trailers. The cost of haulage would be 1½d. per mile per car, working 12 hours a day (Sundays included). The cost of constructing the tramways, providing cars, etc., would be £23,000 for the three miles.

The Japanese Trade.—Mr. Longford, the British vice-consul at Tokio, thinks there is a great opening in Japan for electric machinery. Valuable contracts are often lost at present because it is impossible to obtain specifications and prices from England

Digitized by Google

within the brief period usually allowed for tenders, and he urges that English manufacturers should keep experts on the spot, and that they should work in association either with resident British merchants in Yokohama and Hiogo, or with the great Japanese firms in Tokio now controlling the trade.

Pacific Cable.—In reference to the proposed Pacific cable between Canada and Australia, it is stated that the Canadian Government applied for *pro formâ* tenders from various firms with a view to ascertaining the cost. Eight routes were suggested. The shortest was 6,246 nautical miles, and the longest 7,145 nautical miles. The lowest tender for the longest route ranged from £1,517,000 to £1,880,000, according as the cable were a 12, 15, or 18 word per minute cable; and it provided for a cable ready for operation within two years from the date of the signing of the contract.

Huddersfield.—The minutes of the Electric Lighting Committee, which were passed at the quarterly meeting of the Council, showed that it had been resolved to remit £7. 7s from the original amount of £17. 17s., the charge made for the professional services of the engineer in connection with the installation of the electric light at the infirmary. Petitions were received from various Nonconformist Sunday schools and Bible classes against the running of Sunday trams. Much discussion ensued, and eventually the petitions were read, and referred to the Tramways Committee for consideration and report.

Calcutta.—*Indian Engineering* says: "We learn that a proposal for lighting Calcutta by electricity, and working the tramways by this agency, has been referred to the Government of India in regard to the question of using overhead wires to convey the current. This question is, of course, one of much consequence, both from the suppliers' and the public point of view, and we can quite understand the motives which have prompted the local Government to refer this matter to higher authority." It will be in the recollection of our readers that in our last issue we quoted a paragraph from another Indian paper which denied the above statement.

Beckenham.—At the meeting of the Urban District Council a communication from the National Telephone Company was submitted with a plan showing the position of intended posts to carry wires for fire-alarms and telephone purposes. It appeared from this plan that the company propose to carry the wires entirely on posts placed on the highways. The committee recommended that the subject stand over until this time next year, when the existing agreement will expire, and it may be necessary to make other arrangements. The company's tender for the required fire-alarms was £6 with overhead wires and £38. 10s. with wires carried underground.

Bucklow.—The Clerk stated at a meeting of the Rural District Council that in the agreement with the Altrincham Electric Supply, Limited, there had been an attempt to forestall the Council. The order as drafted, and which came before the Council some time ago, contained one section which was at variance with the terms of the agreement entered into between the company and the Council for the purchase of the undertaking. He had applied to have the terms of agreement incorporated in the Bill. It was stated that the section referred to would only give the Council power to purchase the length of main in Timperley. It was resolved to leave the matter in the hands of a committee.

Llandudno.—At the meeting of the Urban District Council, the Electric Lighting Committee recommended certain conditions relative to the appointment of Mr. A. H. Preece as electrical engineer, the main feature being a payment of 5 per cent. upon the accepted tender. In preparing the plans for the refuse destructor works the engineer was directed to take into consideration the possibility of taking the chimney underground to the top of Bryniau Hill, the site for the destructor to be the most suitable spot at the rear of the gasworks. Mr. Preece had accepted the terms, and the report was adopted. Mr. Joseph Hughes gave notice of motion that a committee be appointed to report as to a road or an electric railway up the Orme.

Cricket.—The Brighton Traffic eleven met the Electric eleven at Preston Park on Wednesday, and the match resulted in a win for the Traffic by 80 runs. Score: Traffic—Aldridge c Ewer b Bunny 33; Vinnicombe lbw b Goddard 19; Cheeseman b Bunny 2; Eames c Ewer b Steers 43; Benford b Steers 4; Sweetman b Butler 5; Moore c Gates b Steers 0; Gillham b Steers 2; Terry b Bunny 4; Johnson not out 0; Sinden b Bunny 0; extras 10—total 122. Electric—Gates b Cheeseman 8; Bunny b Cheeseman 5; Steers lbw b Aldridge 10; Hale b Aldridge 0; Brooks b Aldridge 0; Ewer run out 0; Barnes lbw b Cheeseman 1; Goddard not out 12; Bristow b Aldridge 0; Butler lbw b Cheeseman 0; Martin b Aldridge 1; extras 5—total 42.

Bury.—A deputation from the Bury, Rochdale, and Oldham Tramway Company recently approached the Tramways Sub-Committee with the object of ascertaining "whether the Corporation would look with favour upon overhead electric traction, and on what terms the Corporation could supply power." This was reported to the Sewering, Paving, and Streets Committee, by whom it was resolved "that before any reply be given to the tramway company the Tramways Sub-Committee be instructed to visit Bristol, where the overhead wire system is most successful and in full operation, and report." The sub-committee accordingly proceeded to Bristol last week accompanied by the borough engineer (Mr. Cartwright). The matter is still in a preliminary stage.

Manchester.—According to a report which will shortly be submitted to the City Council, the working of the electric installation in Manchester during the past year has been remarkably successful. Fifty-one miles of single conductor have been laid during the last 12 months, and during the summer of this year it is intended to extend the mains along Great Ducie-street, Bury New-road, Corporation-street, Miller-street, Great Ancoats-street, Lower Mosley-street, Great Jackson-street, Upper Jackson-street, Ardwick Green, Upper Brook-street, and in Victoria Park. Application is about to be made to the Local Government Board for permission to spend an additional £100,000 in the extensions to the plant and mains. A profit of over £11,000 was made in this department last year.

Kingston-on-Thames.—The minutes of the Lighting Committee which were approved at the last meeting of the Council showed that the committee had decided to lay a cable for the supply of current in Queen's-road, Liverpool-road, and Crescent-road, at an estimated cost, with two transformers, of £220. The committee had inspected and approved a specimen street lamp fitted with two incandescent electric lamps, and decided that it should be erected in Pheasant-lane. Further correspondence had taken place with the Maldens and Coombe District Council respecting the laying of electric mains in Coombe, and the matter was still under consideration. The electric launch charging station being now ready, the committee had resolved to fix the charge at 1s. 3d. per unit. Nineteen tenders were received for the supply of coal, and the committee decided to order a sample barge of Messrs. G. E. Wood and Sons' Durham rough small at 10s. 9d. per ton.

Bedford.—At the meeting of the Urban Sanitary Authority the report of the Electric Light Committee, which contained the following recommendations, was adopted: "The Electric Light Committee recommended: (*a*) that the authority become annual subscribers of £1. 1s. to the Municipal Electrical Association; (*b*) that the Bedford Gaslight Company be again requested to remove forthwith their lamp standards from the various streets comprised in the area already lighted by electric lamps, and that unless such request be complied with the authority remove such standards and charge the cost thereof to the company; (*c*) that the common seal be affixed to the following contracts: Messrs. Easton, Anderson and Goolden, Limited, Messrs. J. Oakes and Co., Messrs W. H. Allen, Son, and Co., and Messrs. W. T. Glover and Co. The committee report: (*d*) that during the last two months applications have been received for the supply of electric current to about 550 additional 8-c.p lamps or their equivalent." Applications for the supply of current are coming in very well.

Portsmouth.—The Electric Lighting Committee's annual balance-sheet, made up to March 31, 1896, shows that the revenue for the year was £7,387, while the expenses came to £4,010, leaving a gross profit of £3,377, of which £3,300 has been carried forward to the account of interest on redeemable stock and mortgage debt and the loans fund account for redemption of capital, while the balance has been retained as a reserve to provide for bad debts. The two accounts named absorb £3,749, so that the net deficit on the twelvemonths' working, after the payment of all current expenses and of interest on capital and redemption of loans, is only £419. But in the last three months of the year the gross revenue was much greater than in the three preceding quarters, while the expenditure was reduced, so that for that period there was actually a profit on the entire working. At a meeting of the Electric Light Committee it was decided to place four arc lamps in Pembroke-road, Portsmouth, between the Common and the High-street. When this is done the whole of the current for arc lighting will have been utilised.

Kensington.—The Works Committee report that the lighting engineer has called their attention to overhead wires fixed by the National Telephone Company across Kensington High-street with a distance of 250 yards between the supports, the limit allowed by the London Overhead Wires Act, 1891, unless permission is obtained from the local authority, being 115 yards. The committee recommend that the vestry clerk be instructed to write to the National Telephone Company requiring them to comply with the provisions of the London Overhead Wires Act. The lighting engineer has called the attention of the committee to several electric arc lamps used for private lighting in the parish which are at a less height than 8ft. from the public way, and therefore contrary to the regulations made by the Board of Trade; and they recommend that notices be served for the alteration of the lamps in question. Notices and plans have been received from the House-to-House Electric Light Supply Company relative to extensions of their mains in Gloucester-road and Redcliffe-square; and the committee recommend that permission be given for the work being proceeded with subject to the usual conditions.

Kidderminster.—The Kidderminster and Stourport Electric Tramway Bill has been under the consideration of a Select Committee of the House of Commons. The Bill proposes to make a tramway from Kidderminster to Stourport at a cost of between £30,000 and £40,000, the capital of the new company to be £60,000 with the usual power to borrow £15,000. The only opponents were the Great Western Railway Company, there being no appearance on the part of the Kidderminster Gas Company, who originally petitioned against the Bill. Mr. Balfour Browne, Q.C., and Mr. Lewis Edward were counsel for the Bill, and Mr. Pollock, Q.C., and Mr. Lloyd represented the Great Western Railway Company. Mr. Balfour Browne, in opening the case for the promoters, said the tramway would be four miles long. The feeling of the district was very much in favour of the line, and the consent of the road authorities had been obtained. Certain public improvements in the way of bridge widenings at Kidderminster and Stourpoint would be carried out. The gravamen of the Great Western Railway Company's complaint was the use of elec-

Digitized by Google

tricity at the crossing of the Severn Valley Railway on the level. Whatever danger by leakage could happen to the railway company could be entirely removed by the erection of a wire at a cost of £12. Mr. Garcke, one of the promoters of the Bill, and director of the British Electric Traction Company, said the gross revenue from the line was estimated at £10,000, and the working expenses would not exceed 60 per cent. of the earnings. Mr. J. L Owen, of the firm of Messrs. Dickenson and Co., engineers, Birmingham, engineer to the scheme, said the line would be constructed as an ordinary tramway. The committee decided to allow the Bill to proceed, subject to the insertion of a clause imposing an obligation on the tramway company to contribute an amount to be decided by the Board of Trade, but not exceeding £750, towards the construction by the railway company of a bridge at the present level crossing when public necessity demanded it.

Brighton.—At the last meeting of the Council the following proceedings of the Electric Lighting Committee were conformed without discussion: "This committee meeting on May 4, resolved that electricity mains should be laid as follows: in Grenville-place from Russell-street as far as No. 36, at an estimated cost of £40; in Carlton-hill from Grand-parade as far as No. 27, at an estimated cost of £200, and that the street lamps along the line of such main be fitted with incandescent electric lamps; in Eaton-place from St George's-road as far as No. 42, at an estimated cost of £25 and that the street lamps along the line of such main be fitted with incandescent electric lamps. At a meeting of the committee on May 11, tenders for the supply of armoured and unarmoured lead-covered cables during the year ending May 1, 1897, were submitted, and that of the Callender's Bitumen Telegraph and Waterproof Company, Limited, London, was accepted at the following prices: unarmoured cable—size, ·008; price per rink, £28 · armoured cable — price per mile ·017 square inch cable, £74; price per mile ·05 and ·03 square inch concentric cable, £242. Tenders for the supply of fittings for street lamps were also considered, and the committee resolved to accept that of Messrs. Skeats and Co, Queen's-road, Brighton, to execute the work of fitting up 450 street gas lanterns for incandescent electric lamps in accordance with the specification prepared by the manager of the electricity works, for the sum of £180, with a further price of 8s. for each additional lantern fitted up. Three additional gas lamps were ordered to be erected in Cleveland-road. A letter was read from Mr. J. Penny, stating that he is willing to guarantee the payment of 20 per cent. per annum on the cost of laying an electricity main in Islingword-road as far as his premises, No. 126 in that street. Resolved, that Mr. Penny's offer be accepted, and that the manager be instructed to lay a main from Lewes road as far as 126, Islingword-road, and that the public lamps along the line of such main be fitted with incandescent electric lamps."

Stafford.—The Gas and Electricity Committee submitted their annual report to the Council at the last meeting, for the year ended March 31. It stated that the quantity of gas made during the year was 145,055,000 cubic feet, being an increase on the previous year of 7,045,000ft, or 5·10 per cent. For the first nine months of the year the consumption was at a much greater rate, but owing to the mild weather of the last quarter this increase was checked to a great extent, or the total consumption would have been very much larger than what was now reported. The increase in the receipts for gas was £345. 12s. 9d, and for tar £190. 10s. 9d., and the cost of coal (notwithstanding the large increase in the quantity of gas made) was £537. 17s 5d. less than last year; but owing to the very low prices of coke and sulphate of ammonia (which yielded £535. 0s. 11d. and £465. 19s. 10d respectively less than last year), as well as increased working expenses, the profits were considerably reduced. The receipts were as follows: gas, £17,242. 8s 10d.; coke, £2 254. 0s 8d; tar, £939. 12s. 3d; sulphate, £517. 15s. 7d.; spent lime, £34. 0s. 5d.; and profit on fittings, £134. 10s. 11d.—making a total of £21,122 16s. The total expenditure was £14,066 2s., leaving a gross profit of £7,066. 14s., or £756 2s 11d. less than last year. Out of this amount the large sum of £5,401 3s. 8d. had been paid for interest and redemption of loans, and £261. 1s 2d. for income tax, leaving £1,394 9s. 2d. as the net profit of the year. The sum of £197. 5s. 2d. was brought forward from last year, so that £1,591. 14s. 4d. was the amount now available for disposal. The committee recommended that £1,500 be transferred to the district fund in aid of the district rate, and that the balance, £91. 14s. 4d., be carried forward. The loans repaid now amount to £25,795. 0s. 2d. and (including this £1,500) £26,850 had been handed over in relief of the rates The consumption of gas for cooking, etc., was steadily increasing, and the committee hoped that it would not have to report any diminution whatever on account of the competition of the electric light. With regard to the electricity department, the committee had only five months' actual working upon which to base a report, and it would manifestly be unwise to draw conclusions as to the future until a full year's experience had been obtained. So far, however, everything had been exceedingly satisfactory. No hitch whatever had occurred anywhere, the number of consumers was increasing, and the accounts showed a net credit balance of £296. 11s. 6d. This the committee regarded as very encouraging, and recommended that the whole amount be carried forward to next year. Every indication pointed to the wisdom of the Corporation having control of both systems of lighting, and to their being under the care of one manager and one committee, by whom it was confidently hoped that each system, with its large financial obligations, might prove highly successful and beneficial to the town. In moving the consideration of the report, Alderman Peach said for the first time the accounts had been made up to March 31 instead of March 25, so that they had a week's extra expenditure without the corresponding income. He was pleased to be able to report a continued increase in the quantity of gas consumed, and there appeared to be every reason for believing that the consumption would go on increasing, especially as they had sent out three times as many gas-cookers as in the previous year. After alluding in detail to the report, he said with regard to the coming year the committee had received six tenders for the purchase of their gas-tar but none of them were considered satisfactory. One firm offered considerably higher terms than the others, but they required the committee to erect tar-distilling plant, and this proposal had been referred to a sub-committee to consider. As to the complaints about the stop-pipes at the gasworks the manager had devised a scheme by which the number of stop-pipes had been reduced more than 80 per cent. With regard to the electricity department, although there was a net credit balance of £296. 11s 6d, the actual profit on working expenses was £54. The report was adopted.

Hastings.—The Town Council have decided to lay down an electric light installation. The Public Lighting Committee reported at the last meeting of the Council that, in view of the expiration on July 1, 1897, of the existing contract with the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, for the lighting of the electric lamps on the front line, which they had reason for believing the company would not be prepared to renew for a further period except at a much higher charge per lamp than is at the present paid—viz, £25 per lamp per annum—they had had under serious consideration the question of the desirability of the installation by the Corporation of an electric light system of their own, under the provisional order granted to the Corporation in 1890, which conferred powers for the lighting of public streets and buildings. In accordance with their instructions, the borough engineer prepared plans, and submitted to them a report on the matter, in which he strongly advised the Corporation to undertake their own street, etc., lighting; suggested that the site of the old No. 1 pumping station, at Waterworks-road, adjoining the railway, which is the property of the Corporation, should be utilised for the establishment of a generating station, and that duplicate plant (to consist of two Babcock boilers, three compound steam dynamos and exciters, each capable of maintaining 35 arc lamps, with the necessary switch-boards, testing apparatus, etc.) should be provided, which plant would be sufficient to enable considerable additions to be made to the present number of arc lamps in the town, and to supply current to the town hall, the Brassey Institute, the stoneyard at Queen's-road, and other buildings belonging to the Corporation; pointed out that under provisions of the existing contract with the electric light company the Corporation are, if they themselves determine to undertake the public lighting, bound to take and pay the company for the standards, lamps, cables, pipes, and all other apparatus appliances, and materials relating solely to the public lighting (other than machinery, plans, etc.), by a valuation to be made in the usual manner; and put the estimated cost of an installation on the "alternate transformer system" (that adopted by the electric light company), complete in every respect for maintaining 70 arc lamps and duplicates—including the purchase of the company's plant—at £7,560, and the estimated annual cost of running 50 arc lamps, including interest at 3 per cent. and sinking fund, ample provision for maintenance, deterioration of machinery and lamps, etc., at £1 629, equalling £32. 15s. 7d. per lamp per annum, which annual cost, he intimated, would not be much increased were additional lamps lighted, as the extra cost would simply consist of a small increase in fuel, and the maintenance of the lamps, transformers, etc. It was ascertained that the company would not renew the existing contract on the same terms, but would be prepared to supply energy for the lamps at 5d. per unit, to include cleaning, maintenance, and all charges. At this charge it was calculated that the annual cost of each lamp of the present power kept alight till 11.30 would be £35 and kept alight all night £47, representing an average annual charge of £41. 5s. per lamp, or £16. 5s. per lamp per annum in excess of the present charge. The present annual cost of lighting by gas and electricity the front line and other streets, localities, public buildings, etc., which the committee recommend should be lighted entirely by electricity under the proposed scheme, amounted to £1,902. 10s., but if to this amount is added the increased charge of £16. 5s. per lamp per annum which would be made by the electric light company at the expiration of the existing contract, equalling £845, a total future annual cost of £2,747. 10s. is arrived at. The estimated annual cost of lighting the same streets, buildings, etc., wholly by electricity under the proposed scheme is as under: borough engineer's estimated annual cost of proposed installation (for 50 arc lamps), including charge for interest on loan and sinking fund, £1,639; lighting those portions of the town hall and Brassey Institute now lighted by electricity at, say, 4d. per unit, as against 9d. per unit now charged by the company, £53; lighting the gas lamps and the buildings, etc., above specified, now lighted by gas, £311—total, £2,003. It would be seen from these figures that the carrying out of the scheme would effect an annual estimated saving in the future cost of the lighting of £744. 10s., and the committee, having regard to all the circumstances, recommended that an installation on the lines indicated in the report be established forthwith, and that application be made to the Local Government Board for sanction to the borrowing of the estimated cost thereof—viz, £7,560. Councillor Idenden, as chairman of the committee, moved the adoption of the report. The Deputy-Mayor seconded, and said with regard to the machinery they intended to put it in on similar lines as they had at Tunbridge Wells. As to the present

Digitized by Google

system by which lamps were laid, it was an expensive one, but they intended to keep these as at present, and when they were worn out there would doubtless be improvements in electricity. At Brighton they had the overhanging lamps, which was a better system than they had at present. The report was adopted unanimously.

PROVISIONAL PATENTS, 1896.

MAY 18.

10669. An electrical variable speed gear. Anthony George New, The Voltage, Woking, Surrey.

10670. An electrical variable speed gear. Anthony George New, The Voltage, Woking, Surrey.

10698. Improvements in or applicable to electric alarum apparatus. Henry Charles Bird, 322, High Holborn, London.

10718. Improvements in the manufacture of positive lead electrodes for electrical accumulators. Henri Owen Tudor, 4, South street, Finsbury, London.

10720. Improvements in electrically braking railway vehicles. Illius Augustus Timmis, 2, Great George-street, Westminster.

MAY 19.

10772. Improvements in starting and stopping devices for electrically-operated elevators. Otis Elevator Company, Limited, 55, Chancery-lane, London. (Otis Bros and Co, United States) (Complete specification.)

10781. Improvements in apparatus for the application of electricity to vehicles driven by mechanical means. Herbert John Dowsing, 24, Budge-row, London.

10788. Improvements in electric arc lamps. Ernest John Bagnall, 18, Buckingham-street, Strand, London. (Complete specification.)

10803. Improvements in or applicable to apparatus for heating by electricity. Edward Davies, 5, Market street, Manchester.

10804. Improvements in electric railways. Henry Harris Lake, 45, Southampton buildings, Chancery-lane, London. (Edward Hibberd Johnson and Robert Lundell, United States.) (Complete specification.)

10811. Improvements in the production of electrodes suitable for secondary batteries. Augustus John Marquand and Emmanuel Hancock, 24, Southampton-buildings, Chancery-lane, London

10816. Improvements in electric measuring instruments. James Devonshire, 70, Chancery-lane, London (Elihu Thomson, United States) (Complete specification.)

10817. Improvements in and connected with electric brakes for electrically-propelled vehicles. James Devonshire, 70, Chancery-lane, London. (William B Potter, United States.) (Complete specification.)

10818. Improvements in contact making and breaking devices at drawbridges in the overhead circuit of electric tramways. James Devonshire, 70, Chancery-lane, London. (William B. Potter, United States) (Complete specification.)

10846 Improvements in or relating to magnetically affecting the counter electromotive force of the voltaic arc of an electric arc lamp. William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

MAY 21.

10906. Improvements in and connected with electrical traction. William Kingsland, 33, Chancery-lane, London.

10948. Automatic gear for making or breaking or both making and breaking electrical contacts at given times, which times may also be varied at will. Frederick Brown and Charles Herbert Offord, Fairyfield, Highgate, Walsall.

10949. Improvements in the application of electrical motive power to cycles and road vehicles. Robert Owen Allsop, 37, Norfolk-street, Strand, London.

10988. Electromagnetic gearing. David Cook, 30, Lancaster-park, Richmond, Surrey.

10993. Improvements in electric incandescent lamps. Ernest Bailey and John M. Symington, 47, Waterloo-street Glasgow.

11035. Improvements in the manufacture of electric insulation tubing and electric insulators. Frederick Gwilym Treharne, Wrangbrook, Llanishen, near Cardiff.

11056. Improvements in the means of lubricating the bearings of motor cars or auto-motors. Ernest John Clubbe, Alfred William Southey, and the Electric Motive Power Company, Limited, 55, Chancery-lane, London.

11058 Improvements in motor cars or auto-motors, applicable also to launches. Ernest John Clubbe, Alfred William Southey, and the Electric Motive Power Company, Limited, 55, Chancery-lane, London.

MAY 22.

11133. Improvements in or connected with apparatus for the electrolytic decomposition of liquids. George Bell and George William Bell, 15, Water-street, Liverpool.

11162. Electric alarm apparatus. Frederick William Golby, 36, Chancery-lane, London. (Heinrich Winter, ———.) (Complete specification.)

11176. Improvements in electrical boilers for heating water and other liquids. John Chambers, 7, Staple-inn, London. (Date applied for under Patents, etc., Act. 1883, Sec. 103, December 5, 1895, being date of application in New Zealand.)

11212. Improvements in dry cells for galvanic batteries. Thomas Clark, 24, Southampton-buildings, Chancery-lane, London.

11216. Improvements in electro-chemical apparatus. Chester Dawson, The Mount, Hampstead, London. (F. Manza, Austria.)

11230. Improvements in electrical regulating apparatus for arc lamps. Henri Pieper Fils, 47, Lincoln's-inn-fields, London.

11232. Improved electric current conducting apparatus for electric railways Carl Friedrich Phillipp Standebach and Oskar Hermann Linker, 18, Buckingham-street, Strand, London. (Complete specification.)

MAY 23.

11249. Improvements in the method of and apparatus for driving electric cars. William Griffin, Commercial-street, Halifax.

11329. Improvements in electric railway signals. Wilhelmine M. Klees, 126, Carlton-vale, Maida Vale, London.

11338. Improvements in electrodes for electrolytic purposes. Ernest Auguste Georges Street, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1895.

8696. Electric distribution. Wright and Quin.

11233. Arc lamps. Peschek.

12035. Cutting off gas or electric current. Phipps.

24375. Electric arc lighting. Hegner.

1896.

977. Synchronising alternating-current motors. Parshall.

2003. Telegraph repeators. Lake. (Merritt.)

NOTES.

Dundee Institute.—An excursion to Inchcolm, etc., has been arranged for June 30.

Geneva Tramways.—The Swiss Federal Council have authorised the opening and working of three new electrical tramways in Geneva.

Sir George Stokes.—Sir George Stokes, Lucasian Professor of Mathematics at Cambridge University, has been elected an honorary member of the Austrian Academy of Sciences.

Chemical Society.—A meeting of the Research Fund Committee will be held in June. Applications for grants, accompanied by full particulars, should be sent to the secretaries before June 8.

The Amazon Cable.—The rates for telegrams to Souré, Mosqueiro, Pinheiros, Cametá, Breves, Gurupá, Chaves, Macapá, Monte Alegre, Santarem, Alemquer, Obidos, Parintins, Itacatiara, and Manáos on the Amazon have been published in the *Gazette*.

Royal Institution.—To-night (Friday) Prof. Fleming lectures at the Royal Institution on "Electric and Magnetic Research at Low Temperatures." With the exception of Mr. Martin's lecture on Niagara on June 19, this is the last of the Friday evening meetings.

Institution of Electrical Engineers.—There is to be a students' visit to the Bankside station of the City of London Company on June 10, at 7.30 p.m. Students desiring to take part in it should forward their names to Mr. G. C. Allingham, at Eldon House, Lyndhurst-road, Hampstead, N.W.

Calcium Carbide.—According to *Elektrotechnische Blätter*, the Swiss Federal Council have decided that carbide of calcium can only be received for carriage on the railways when packed in hermetically-closed iron cases, by which it is to be presumed only air-tight iron cases are meant. No other substances may be packed with the carbide.

Obituary.—The death has been reported of Dr. Henry C. Nicholson, who was prominently concerned with the invention of quadruplex telegraphy. Dr. Nicholson died at his home near Independence, Kentucky, at the age of 74 years. He received a stroke of paralysis about six weeks prior to his death, from the effects of which he never recovered.

New Cable to Germany.—The shore end of the new submarine cable to Germany was landed by the steamship "Silvertown" at Bacton, on the Norfolk coast, last week, and the "Silvertown" then steamed away in the direction of Germany, paying out the cable as she went. Mr. Lamb, assistant secretary of the General Post Office, superintended the arrangements.

The Telegraph Conference.—Mr. J. C. Lamb, C.B., C.M.G., Mr. H. C. Fischer, C.M.G., and Mr. P. Benton will represent the Government of this country at the international telegraph conference, which meets at Budapest on June 16. These delegates will also represent the Cape Colony and Natal. Mr. R. J. Mackay has been appointed secretary to the delegation.

Committee on Rails.—The President of the Board of Trade has appointed a committee, consisting of Lord Blythswood (chairman), Sir Benjamin Baker, Sir J. Lowthian Bell, Prof. Wyndham Dunstan, Prof. A. B. W. Kennedy, Major F. A. Marindin, Mr. E. P. Martin, Prof. W. C. Roberts-Austen, Dr. T. E. Thorpe, Prof. W. C. Unwin, and Mr. E. Windsor Richards, to enquire into the loss of strength in rails by prolonged use.

Street-Lighting.—The New York *Electrical World* states that arrangements have been perfected for a convention of the superintendents of street-lighting from all parts of the United States to be held in New Haven, Conn., this month. The plan is to have a two days' meeting of all the street-lighting officials and authorities for the benefit and mutual aid of every city which sends delegates. This will be the first convention of the kind held in the United States.

Sheffield Exhibition.—These columns have occasionally contained announcements of exhibitions to take place in various parts of the world which are not nearly so well known to Englishmen as Sheffield. That city was, however, to have had an exhibition of some kind or other this summer, but it does not appear to have come off. A site was secured, and, what is of equal importance, exhibitors were believed to be ready, but the exhibition has not been opened, nor, so far as it can be ascertained, is it likely to be at present.

Accidents in France.—It appears to be considered across the Channel that if an accident happens there must be someone made responsible. A peasant having been killed and another seriously hurt by coming in contact with overhead wires which had been blown down by a storm, two of the managers of the electric works at Saint Victor-sur-Loire were placed on their trial before the Correctional Court on a charge of killing and wounding by neglect. The Court, however, promptly acquitted them.

Brush Electrical Engineering Company.—We have received from the Brush Electrical Engineering Company, Limited, a copy of the second edition of their book of working instructions for the use of their plant. This is a well-turned-out little volume, morocco bound, with soft covers and rounded corners so as to adapt itself to the pocket of the electrical engineer, where, doubtless, it will be found in all stations using the Brush Company's machinery. The 63 pages of descriptions and instructions for use could hardly have been issued in a more convenient form.

Swiss National Exhibition.—It is a common complaint that exhibitions are opened long before most of the exhibits are in place and ready for inspection. It may, therefore, be of interest to visitors to Geneva to know that, according to the *Revue de l'Electricité* of May 31, sections 29 and 38 (machinery and industrial electricity) are sufficiently complete to repay inspection and study. Among the exhibits it may be noted that the Oerlikon Company show a 750-h.p. continuous-current dynamo designed for electro-metallurgical work. An interesting feature of the section will be the triphase and polyphase motors of various makers.

Book Received.—We have to note the receipt from Messrs. Whittaker and Co., White Hart-street, Paternoster-row, of "Engineer Draughtsmen's Work." The author, "A Practical Draughtsman," is anonymous, and the object of the little book is to provide a quantity of hints and information likely to be useful to the large number of aspiring young men in schools and workshops who desire to obtain entrance into drawing offices, but who are often in considerable ignorance of the work that is really carried on in such places, of what will be required of them when they get there, and the instruments and appliances which they will need to be familiar with.

Insulating Material.—From a French source, it appears that an insulating material for wires is manufactured by Anderson, of Stockholm, by treating a fatty oil—such as resin oil—with 20 to 30 per cent. of concentrated sulphuric acid at a low temperature. To this

Digitized by Google

is added cellulose or moistened cotton, and the whole is heated to 110deg. C., and pulverised sulphur is added, which is followed by a reaction which completely changes the consistency of the material. A further large quantity of sulphur is added, and the material is then poured into cold water, after which it is rolled between cylinders and combined with rubber, guttapercha, resin, or paraffin, according to the purpose for which it is to be used.

The Kelvin Jubilee.—The Senate of the University of Sydney, N.S.W., have appointed the chancellor, Sir William Windeyer, LL.D., and Prof. Liversedge, M.A., F.R.S., the dean of the Faculty of Science, who are at present in England, to represent them at the University of Glasgow on the occasion of the Kelvin jubilee. We gave last week the programme of the celebrations. As it will be impossible for all the students and student delegates from foreign universities to be present at the conversazione on June 15, the joint committee of the Students' Representative Council and the University Union have arranged as an alternative for a smoking concert at the Union. Mr. H. Goodman is the secretary of the committee, and applications should be addressed to him.

Helium.—Argon and helium have from the first acted very improperly from the theorists' point of view, in that they have consistently behaved like monatomic gases, while if that supposition is adopted it is impossible to find any place for them in the Mendeleief arrangement of the elements. Prof. Ramsay has now discovered that helium diffuses more rapidly than from its density it ought to do, a result which may be at once correlated with its abnormally high conductivity. Evidently what are practically first approximations will no longer do, and the whole of the kinetic theory of gases will have to be overhauled and brought up to date. In one way and another, it would seem that the "mathematics and physics" people have plenty of work before them.

Canal Traction.—It is stated in *L'Electricien* that the Administration des Ponts et Chaussées of the French Government have under consideration the establishment of a system of electric traction on the River Lot, which will take barges up as far as the Aveyron coalfields. Water power from the natural fall of the river is to be used to generate the current, and it is considered that the installation of some such system of barge traction is the only means of reviving the navigation of the river, which has greatly fallen off. On the other hand, as the Aveyron coalfields produce more than a million tons of coal a year, it is thought that it would be a matter of great importance to establish a convenient and cheap system of water communication between them and the district and port of Bordeaux.

Church-Lighting Extraordinary.—At St. Ignatius's Church, in Hayes-street, San Francisco, about £6,000 has been spent in obtaining stained-glass windows from Germany, and now it is found that it is no good, since at the evening service, which is the important one in most American churches, no one can see them. As an American contemporary puts it, "Owing to the construction of the church, their beauty is absolutely lost after dark." Probably the architect is not very much in fault, as most churches are constructed in that way, but, all the same, the Californians do not intend to go without a show for their money. Consequently they have called in the aid of the electric light, and fixed arc lamps outside the windows. The congregation appeared to have liked the effect so much that the arrangement is to be a permanency, and the church authorities are now discussing the best arrangement of reflectors.

Chicago Tramways.—From statistics issued in Chicago, it appears that 10 years ago there were but four tramway companies in Chicago, capitalised at 11,437,000dol., and working a street mileage of 90 miles. To-day there are 10 distinct corporations engaged in local transportation business, having an aggregate capitalisation of 187,208,000dol., and operating 32 miles of street mileage. Of the four systems in existence 10 years ago, three were worked entirely by horses, the fourth using both cable and horses. Now the horse car has practically disappeared from Chicago, the motive power at present being—Surface roads: electric, 255 miles; cable, 42 miles; horse, 18 miles. Elevated roads: electric, 15 miles; steam, 11 miles. In addition to the roads now completed, construction work is rapidly progressing upon five surface and elevated roads, all to be worked by electricity, and which will, when completed, increase the total city mileage to 400 miles.

Semaphore Signalling.—We have received from the author, Captain C. Vreede, who is a retired commander of the Dutch Royal Navy, a pamphlet on a so-called international code of signalling. The main feature of the pamphlet is a proposed alteration in the code to be used, by which the Morse code is rejected in favour of the signals afterwards described. We have carefully read the author's justification of his proposed change, but the evidence brought forward does not seem to be by any means sufficient to warrant the departure from the Morse code now that the latter has secured almost universal acceptance. Apart from this radical fact, the pamphlet shows that the author has devoted much time and careful study to perfect his system and the various mechanical apparatus used in it. It is a pity, however, that more care has not been taken in the translation of the pamphlet into English, as some of the sentences in it are at present unintelligible. Sound and night signalling gears are also described.

Tramcars and Lightning.—The erratic ways of lightning have always been proverbial, and even the best-devised lightning-arresters cannot do everything. A case has been reported from New Brunswick, in the State of New Jersey, in which a trolley car was struck by lightning on the afternoon of May 5 during a thunderstorm. According to the *Scientific American*, the discharge passed down the trolley pole and entered the car, part of the current running on to the lighting circuit and burning out the incandescent globes. "So intense was the heat in the lamps that the glass globes melted; most of the glass fell on the floor, but other drops went into the laps of women and more fell on their hats. The ladies thought they had cause for complaint, and demanded that the company should make good the damage to their garments." It is satisfactory, however, to see that, even if a lightning discharge or a portion of it does get into an electric tramcar, the danger of the passengers is confined to the risk of broken glass.

American Electric Trams.—The *Times* has published a letter from "Union Jack," who, writing from Kingston, in the State of New York, wishes to warn Englishmen against adopting electric traction on tramways on account of its danger. "Union Jack" has apparently been frightened by the Brooklyn tramcars, which are notorious even in America, and hopes that "every effort will be made to keep these death-dealing vehicles out of the Metropolis." In the course of his letter, "Union Jack" shows that he has no technical knowledge of the subject, and therefore it is not very wonderful that he has failed to see that the perils he fears are simply due to the American way of doing things, and not in any respect to the inherent dangers of the system. Yet, curiously enough, he puts his finger on the exact spot when he says,

Digitized by Google

"Over here (*i.e.*, in New York) the almighty dollar rules the roost, and life and safety are a secondary matter." The attitude of the people who are utterly careless of old and known dangers, but panic stricken at the hint of a new one, is eminently absurd, but it has to be reckoned with; and bad as is the record of the Brooklyn trams, it would look very different when compared with the record of cart and cab accidents during the same period. The different ideas on the subject of safety which show themselves in the working of English and American railways would undoubtedly have the same effect in tramway working.

A New Education Scheme.—In an age of payment by results and of competitive examinations in educational work there is a tendency to act as though all boys may be ground into one mould. It would be so convenient to the educator if it were so, and as things are it may even pay him best to throw out the specimens he cannot so mould as "wasters." Some remarks of Mr. Charles Bright on the subject in a short leader in the *Referee* may therefore be worth consideration. The man best qualified to pass examinations with high honours may be the least fit to teach others, as he is apt to attach undue importance to his own method of obtaining success. In Mr. Bright's system, as we understand it, a liver test would be employed simultaneously with that on literary subjects. Then the boy whose health is affected least by the application to hard brain work would receive a large bonus in marks. The main feature of the proposed system is, however, the selection of real live men as masters rather than the bookworms with high university degrees—a man with a business knowledge of the world and a healthy physique, who, having a knowledge of the relative values of study and manliness, can train the boys under their charge and bring out the good points in each. At the same time they could acquire a knowledge of the capabilities of each, and check the tendency which leads so often to a useless life after a school career full of success. The boys then would have a chance of entering a profession to which they had shown some aptitude, and the dangerous and costly change from one career to another later on in life would be avoided.

Telegraphic Communication.—The fool's paradise in which we are dwelling in this country in reference to the integrity of our telegraphic communications in case of war has more than once been dealt with in this journal. Somewhat similar views have been strongly enforced by Mr. Percy Hurd in the current number of the *Contemporary Review*. There are, he says, two telegraphic routes with South Africa, the East Coast and the West Coast. The East Coast line touches Portuguese territory at three points; the West Coast touches both Portugal and Porto Novo, which belongs to France, and, moreover, passes through a region where white labour is almost impossible. Three sections of the West Coast route were in January, in the midst of the Transvaal difficulty, interrupted by the burning of rubbish at the water's edge. Mr. Hurd appends a formidable table of interruptions in both routes during the last six years, from which it appears that the East Coast route was on one occasion interrupted for 114 days in succession; the West Coast route having once been interrupted for 50 days. Nor are things so very much better as concerns our other colonies. "No single possession in east longitude is connected telegraphically with London without the passage of the wires over some foreign territory, or their landing at a number of foreign ports." With the West Indies our communications are equally at the mercy of other people. "To reach Jamaica, Barbadoes, and Trinidad, British messages must pass over United States land lines, and thence *viâ* Cuba or *viâ* Galveston (Texas) and Panama, through revolution-ridden republics in Central America." War with the United States would find the islands of the West Indies cut off from us. Such a danger ought to be met by the construction of all-British cables, and Mr. Hurd endeavours to show that the cost is not prohibitive, and that our Colonies are quite willing to contribute to it.

The Pacific Cables.—The Imperial representatives on the committee of enquiry into the scheme for connecting England with her Australasian colonies by telegraphic cable, *viâ* Canada and the Pacific, have not been definitely appointed, but it is probable that Lord Selborne, Under-Secretary of State for the Colonies, will be one of the two, and that there is a feeling in favour of requesting him to preside over the deliberations of the committee. It is intended to hold two meetings of the full committee as soon as may be to settle questions of principle, but the Australian delegates — namely, Sir Saul Samuel and the Hon. Duncan Gillies—will then have to leave to attend the Telegraphic Conference at Budapest. The meetings of the committee will be as informal and business-like as possible; and they will not be open to the Press. Meanwhile the rival Pacific cable from the United States to Japan appears to be getting on. We noted at the time that it had passed the Senate, and the Committee of Commerce of the House of Representatives have now authorised a report to be presented in favour of the Bill, which provides that the American Postmaster-General may contract with the Pacific Cable Company of New York for the construction of a cable from the United States to Hawaii, Japan, and China, *viâ* the Medway Islands. In one way or another the Americans, who are fond of doing such things, will soon be able to send a telegraphic message round the world from one side of a dinner table to the other instead of having to be content, as at the opening of the New York Exhibition, with a long loop to Japan and back again.

Electric Traction on Railways.—We have repeatedly referred to the interest taken in America on the subject of the application of electric traction to ordinary railway working and the care with which every possible saving that might follow the adoption of this method has been discussed in the technical Press. It seems that the *Canadian Engineer* is even more sanguine on the subject than its contemporaries in the States. In this month's issue of that journal Mr. J. H. Kelley is responsible for an article which begins as follows: "It is difficult to move people out of the beaten track, and after 50 years' experience of steam traction for railways, it is only natural that the idea of employing electricity as a substitute for steam should be a little slow in making its way. It may not be long, however, before we see most of the railways now operated by steam locomotives adopt electricity as a means of traction, distributing it from a series of central power stations at suitable distances apart. Among the advantages of this system of operation would be the economical production and distribution of power from a station for a stretch of road on each side. There will be a pair of condensing engines, or, more economical still, a gas-engine, using about one-fifth of the fuel required by the locomotive of the best type. Each pair of engines would handle six passenger or freight trains, thus making two cylinders do the work that now requires 12, the labour of six engineers and foremen being replaced by that of half that number. The locomotive is not economical either in the production of steam in the boiler or in distributing it as power. In the locomotive the ratio of expansion at slow speed is very wasteful, and under the changing conditions of load and weather it is not possible to run the locomotive economically. On the other hand, the automatic cut-off

Digitized by Google

compound engines attached to the latest design of dynamo placed direct on the shaft can in most instances be relied upon to generate 1 h.p. per hour per 2lb. of coal."

High-Voltage Lamps.—The New York *Electrical Engineer*, which has reprinted in full Mr. Addenbrooke's Institution paper on high-voltage lamps, regrets that the subject was not touched upon during the discussions at the recent meeting of the National Electric Light Association at New York. From the steadily increasing use of 220-volt incandescent lamps, our contemporary considers that the inference is fair that with the lapse of time their employment will cause the general displacement of the time-honoured 110-volt lamp. It is, however, pointed out that at the same efficiency a 220-volt lamp must have a filament four times the resistance of a 110-volt lamp, and with the same surface. "This means a very long and very thin filament, and such filaments are at once difficult to make and hard to support in the bulb, owing to their great length and lack of stiffness. Regarding the efficiency of such lamps, the fact must not be lost sight of that, owing to their extreme thinness, these filaments are much shorter lived than the thicker 110-volt filaments at the same efficiency, and in order to render them commercially useful they are drawn to consume four watts per candle. This lower efficiency makes the filament thicker, besides lowering its temperature of operation. These relations seem bound to exist in lamps made by the present methods, using hydrocarbon treatment, and any improvement which produces a good three-watt 220-volt lamp will probably make a corresponding improvement in the practical efficiency of the 110-volt lamp." Though it is not made in so many words, the natural inference from this would seem to be that in deciding whether in any particular case a voltage of 220 or 110 should be adopted, no allowance need be made for a probable improvement in the efficiency of the high-voltage lamp. The article closes with the statement that enquiry has developed "the fact that during the past year one company alone sold 10,000 240-volt lamps, and that their quality is constantly improving, so that as good results are obtained in practice from a 240-volt lamp as from the 3·1-watt 110-volt lamp."

Town Telephone Wires.—Some interesting particulars have been obtained by Mr. Gordon, the town clerk of Aberdeen, as to the conditions under which various town councils allow the erection of telephone poles and wires on and across the streets. Mr. Gordon has communicated on the subject with a number of towns in England and Scotland, and from a memorandum he has issued it appears that in Edinburgh a small charge is made for each pole and wire attached to the pole. The Glasgow Town Council do not allow telephone poles to be erected in public streets or lanes, but overhead wires are fixed on the buildings in the streets by arrangement with the proprietors, and without permission from the Corporation, except in the case of buildings belonging to the Corporation. In Dundee a charge of 1s. per pole per annum is made for permission to erect poles in the streets. In Birmingham the wires are all laid underground, as the Corporation object to the erection of poles in the streets. In Bradford a charge of £5 per annum is made for leave and license, and 1s. per annum for each pole placed in a public thoroughfare. Only in exceptional circumstances is permission given for the erection of poles in public streets in Brighton, and in these cases a charge of 1s. a year for each pole is made. In Bristol the Telephone Company is charged 20s. per annum for each pole they erect in the public streets, and the Corporation charges individuals 10s. per annum for every quarter of a mile of wire which crosses a public street. No special condition is attached to permission for the erection of overhead wires in Cardiff other than that contained in the Corporation by-laws, which provides as to the height at which wires are to be placed above the street. The rental charged in Leeds for poles and wires fixed in the highways is 20s. per mile per annum for not exceeding eight wires, and 2s. 6d. for each additional wire. The Corporation of Manchester do not sanction the erection of poles in streets except a few in the outlying parts of the city belonging to the Postmaster-General. In Newcastle a charge of 1d. per pole per annum is made, but overhead wires are not permitted in the central parts of the city. In nearly all cases it is stipulated that the poles must be removed if required by the Corporation.

Tramway Brakes.—It is remarked in *L'Electricien* that a tendency to an increased speed manifests itself whenever mechanical or electric traction is substituted for the old-fashioned horse-drawn tramcars. Speeds of 10 to 12 miles an hour have become quite frequent, and in a town these cannot be considered as other than fast. It consequently follows that the numerous stoppages and the obstacles in the way of street traffic, coupled with the increased weight of the new motorcars, which often carry also a trailing car behind, have obliged the tramway companies to supply their rolling-stock with brakes of considerable power, and so far as may be instantaneous action. The hand-brake having been recognised as too weak, it was at first endeavoured to apply to tramway work the well-known brake used on the Paris omnibuses. Excellent as this is in some respects, it had the fatal defect of only acting in one direction, so that in case of a stoppage in going up a steep incline there would be nothing to prevent the car starting off to run down backwards. Many proposals for electric brakes have been made, of which the majority work on the principle of cutting off the driving current and short-circuiting the motor. This is effective in a fashion, but the stoppage is not a quick one, since the braking effect diminishes with the speed. Moreover, nearly all the energy of the moving vehicle reappears in the form of heat developed in the coils, and these may therefore easily be damaged, while if resistances are thrown in to keep the current below a safe limit in this respect the braking effect is diminished. Moreover, the wheels may skid. The result is that it has been necessary to fall back on the solution of the brake question adopted by the railway companies, though with some modifications—namely, brake blocks acting on the tyres, and driven in one way or another by air pressure. As, however, it is difficult in any of these systems to entirely suppress a certain amount of air leakage, the cost of which would have to be reckoned with in tramway working, our contemporary refers at some length to what are called hydro-pneumatic brakes, the name being, as we consider it, a somewhat inaccurate one, as it is air and oil that are really used, and not water and air. As an example of these, the Boston Lombard Company's brake is chosen, in which a quantity of mineral oil is interposed between the compressed air and the piston which works the levers and rods acting on the brake blocks. The particular oil chosen is "valvoline," which is not only free from any difficulty in the way of freezing, but has advantages in the way of the lubrication of parts which be practically inaccessible for that purpose in the ordinary way. After some reference to the well-known points common to all air-brakes, our contemporary concludes with the remark that the hydro-pneumatic brake has given excellent results in working, and deserves to make its way in Europe.

Rontgen Radiations.—It is understood that among the select few in this country who are entitled to pro-

Digitized by Google

nounce on the subject it has now been pretty generally agreed that the Röntgen radiations are really transverse vibrations which differ from light waves only in their being of extremely small dimensions. If that is so, the subject belongs no longer, except indirectly, to the domain of electricity, but must be classed under "radiation and light." It may be remarked that from the very first it was pointed out in this journal that there were what seemed to be conclusive reasons why the new radiations, whatever they were, could not be the longitudinal vibrations which their discoverer and many others believed them. But negative evidence of the "cannot be this, so it must be that" order, however cogent, is always less satisfactory than a direct proof. If they can be confirmed and repeated, this has been supplied to a certain extent by some experiments made by Prince B. Galitzin and Mr. von Karnojitzky, and communicated to the Imperial Academy of St. Petersburg. As the proceedings of this body are probably not very accessible to English readers, it may be mentioned that Prince Galitzin tried to polarise the Röntgen rays. First he used Nicol prisms, and naturally got negative results. Considering what was already known as to the properties of the new radiations, that was not surprising. Ultimately he fell back on exceedingly thin slices of green-brown tourmaline, which works on a different principle, and then got evidences of polarisation in the way of a greater apparent opacity when the tourmalines were crossed. As has been said before, the experiments require repeating, but if they are confirmed they settle the question. So far as practical matters are concerned, it is announced from Berlin that the General Electrical Association have succeeded in so improving the Röntgen process as to render it possible for the internal structure of the head, the larynx, and more especially the action of the respiratory organs and heart, to be observed direct on the fluorescent screen. Except in the case of the head, which, from the greater imperviousness of bone presents special difficulties, there is nothing particularly impossible in this. In reference to the head, however, it is to be feared that every anonymous photograph put forward as taken by the Röntgen method is not necessarily genuine. Finally, Mr. Edison has made a discovery. This is a new lamp, and consists apparently of a Crookes tube, about 5in. long, coated inside "with some kind of crystals easily obtainable, the exact nature of which the inventor refuses to disclose." Mr. Edison's favourite up to the present has been tungstate of calcium, but the description does not fit this very well. These crystals fluoresce and give off light when the discharge passes. The practical difficulties in the way of the use of the very high voltage current necessary for "vacuum tube" work are not mentioned. Of course, the thing is far from having attained a practical stage, but it is so very much easier to convert too short waves into longer ones than to change the too long (heat) waves into the shorter light ones that it is likely enough that some day a more economic lamp than the carbon filament one may in this way be attained. Nothing further has been heard from the Halle professor who thought he could see the Röntgen rays. This observation will probably have to go the way of the plate-box that perplexed the readers of *Knowledge*.

Alternate-Current Dynamo-Electric Machines. The paper on this subject by Dr. J. Hopkinson, F.R.S., and Mr. E. Wilson, read before the Royal Society, and abstracted from the *Phil. Trans.*, deals experimentally with the current induced in the coils and in the cores of the magnets of alternate-current machines by the varying currents and by the varying positions of the armature. It is shown that such currents exist and that they have the effect of diminishing to a certain extent the E.M.F. of the machine when it is working on resistances as a generator without having a corresponding effect upon the phase of the armature current. It is also shown that preventing variations in the coils of the electromagnet does not, in the machine experimented upon, greatly affect the result, and that the effect of introducing copper plates between the magnets and the armature has not a very great effect upon the E.M.F. of the armature, the conclusion being that the conductivity of the iron cores is sufficient to produce the main part of the effect. A method of determining the efficiency of alternate-current machines is also illustrated, and the results of the experiments for this determination are utilised to show that in certain cases of relation of phase of current to phase of E.M.F. the effect of the local currents in the iron cores is to increase instead of to diminish the E.M.F. of the machine. In algebraic discussions of the theory of alternate-current machines, it has usually been assumed that the E.M.F. due to the magnets is a periodic function, the same whether there is a current in the armature or not, and that the effect of the current in the armature can be represented by regarding the armature as having self-induction. It has been pointed out, too, that the coefficient of self-induction will generally vary with the position of the armature in the field. To state exactly the same thing in another way, it has been assumed that the E.M.F. of the magnets is a periodic function independent of the current in the armature, and that the effect of the armature current on the induction through the armature can be represented as an armature reaction which vanishes at the moment when the current in the armature vanishes. In machines as ordinarily constructed, the current in the magnet coils is not compelled to be constant, and any rapid variation of the induction in the magnet cores will induce currents in those cores. The variations in the current in the magnet coils and the currents in the cores both tend to annul the variations in the induction in the core arising from the current in the armature, but they will not tend to alter the average effect of the currents in the armature on the induction through the magnets. That there will be such an average effect is not difficult to see. Suppose the armature coils to be fixed in line with the magnets of the machine, any current in the armature will have its full effect in increasing or diminishing the field through the magnets. Suppose the armature coils to be fixed midway between the magnets, any current in the armature will then have practically little or no effect in increasing or diminishing the field through the magnets. If the armature be connected through resistance, inductive or non-inductive, and the machine run in the ordinary way, the current in the armature will lag in phase behind the E.M.F. The result is that when the armature is opposite to the magnets there is a current in the armature tending to demagnetise the magnets, and adding together the effects of the armature in all positions, there is an average effect tending to demagnetise the magnets. If the machine had a constant current round the magnets and divided iron in the magnets, this average effect, as well as its variations, can be fully accounted for; call it self-induction or call it armature reaction, as you please. But inasmuch as the variations are in part annulled by the variations of current in the magnet winding and the local currents in the magnet cores, we have a part of the diminution of the E.M.F. of the machine unaccompanied by retardation of phase of the current in the armature.

A NEW TRANSMISSION DYNAMOMETER.*

BY S. W. ROBINSON, PROFESSOR OF MECHANICAL ENGINEERING, OHIO STATE UNIVERSITY.

In designing and equipping a machine shop, or, in fact, a manufacturing establishment of any kind, one of the first problems met with, as touching economy and efficiency, is the amount of power required to run the plant. In olden times when the teeth of gear wheels were chipped and filed, and engine cylinders were bored by pushing a hand tool along a plank, this expense was either boldly guessed at, or roughly estimated according to the number of men employed—1 h.p., for instance, being considered sufficient to drive a suitable number of machine tools to keep 10 men at work. In modern times, however, where every possible leakage must be looked to with the greatest care, it is not only desirable, but absolutely essential to the welfare of the concern that an accurate knowledge should be had of the amount of power developed by the motor and the amount required to drive each machine.

The only satisfactory method of ascertaining these quantities is by the use of some form of dynamometer—by which we mean an instrument or machine for measuring the power exerted by an engine or electromotor, or the amount of power consumed in driving a single machine or machinery plant. A dynamometer is primarily an instrument to measure the work done by an effort of some kind, the result being usually expressed in foot-pounds and given in a lump sum, as 10,000, meaning 10,000 foot-pounds: as in the case of the integrating dynamometer. But more frequently the result is a diagram area, as by the recording dynamometer, which area, when measured by duly considering the co-ordinates and determining the area, represents the foot-pounds. Thus, the steam-engine indicator is in one sense a recording dynamometer, because the pressure ordinates of the indicator diagram multiplied by the stroke abscissæ gives an area which represents the foot-pounds of work performed by the engine for the corresponding stroke of that engine.

Sometimes the pressure or force ordinates only are indicated by the instrument, the space ordinates, or abscissæ, being determined by some other means than by the so-called dynamometer. Thus the work done in drawing a plough along a furrow may be measured by observing at frequent equal intervals a spring dynamometer applied between the plough and whiffletree, while the distance, or space passed over by the plough at the same time, is measured by a tape line or similar means. Then, multiplying the mean tractile force, in pounds, given by the spring dynamometer, by the space in feet will give the foot-pounds of work which was required for turning the furrow by the plough and team, the entire work, friction, and all, being measured. An ordinary spring balance for weighing may thus be used for a dynamometer, from which it may seem that this instrument is named according to the service required of it, as spring balance, dynamometer, etc. Dynamometers are divided into two classes—viz., absorption dynamometers and transmission dynamometers, the former being specially adapted to the measurement of the power developed by motors, by absorbing or neutralising it, usually by friction, but not applicable for measuring the power required to drive a lathe or grinding-mill; while the second, or transmission dynamometer, is especially adapted for determining the amount of power necessary to drive a machine by measuring it while being transmitted to the machine. The transmission dynamometer may, however, be used also for ascertaining the power of motors, the instrument being applied near the motor and transmitting all its power.

According to Morin, the sensibility of a dynamometer should be proportional to the intensity of effects to be measured, and should not be liable to alterations by use. The indications of flexures should be obtained by methods independent of the attendance, fancies, or prepossessions of the observer, and should consequently be furnished by the instrument itself, by means of tracings, or material results, remaining after the experiments. The observer should be able to ascertain the effort exerted at each point of the path described by the point of application of the effort, or, in certain cases, at each instant in the period of observations. If the experiment from its nature must be continued a long time, the apparatus should be such as can easily determine the total quantity of work expended by the motor.

To meet these conditions various instruments have been designed by Morin, Webber, Briggs, Tatham, Brackett, Hartig, and others, all of which are sufficiently accurate for practical purposes. But, in addition to possessing accuracy, and the other qualifications already mentioned, a dynamometer should be simple in construction, light for transportation, quick in adaptation, easy to read, and the results such as can be rapidly converted into the horse-power transmitted, and, above all, the machine sufficiently cheap to be within reach of every manufacturer.

To this end, after a fruitless search in the market for a truly desirable instrument, the transmission dynamometer illustrated in Fig. 1 was designed and built by the writer for the testing laboratory of the Ohio State University, where it has done admirable service. This machine consists essentially of a supporting frame, or pedestal, a T-shaped arm carrying the driving mechanism, and a graduated scale or weighing apparatus.

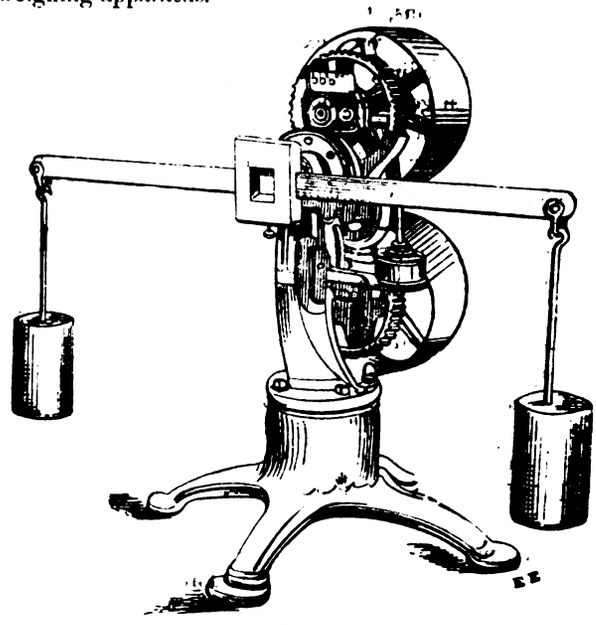

FIG. 1.

To use the instrument it is made fast to the floor with the pulleys under or to one side, but in the plane of the belt which drives the machine, the power to drive which is to be measured. Then with the machine set as shown in the illustration the lower pulley of the dynamometer is connected with the machine, while a second belt connects the pulley on the instrument with the pulley on the power shaft. This arrangement of pulleys enables the observer to connect his instrument without moving either the machine to be measured, or the driver on the main line.

The two pulleys of the instrument are mounted on a strong cross-tree bar so that they both overhang and can be swung around to any position. This overhang and swing makes it convenient to put either belt on or off without unlacing, and to swing the pulleys either way for tightening or loosening both belts. We may say, as a rule, both belts, for in setting the instrument up we can so set it, both as to location on the floor and position of cross-tree bearing, that by swinging the cross-tree one way we tighten both, or the other way loosen both belts. This movement of the cross-tree is made possible, and even convenient, by the cylinder and flange connection to the head of the column, the latter having screws and slots covering the full circle, so that the cross-tree may be set free to turn, and again made fast in any desired position. Thus the two pulleys may be swung about to any position in the whole circle to suit the particular location in hand. In swinging the pulleys and cross-tree thus, the set screw, making fast the poise-bar, should be slackened and again tightened when

* From *The Digest of Physical Tests.*

Digitized by Google

the desired position is found. Thus the driving belt may come down from above, from the one side, or from below to its proper pulley on the short arm of the cross-tree; while the pulley on the longer arm is to be connected to the machine to be measured, the cross-tree being first set, if desired, so that both belts are loosened or tightened simultaneously, due regard being paid to the poise-bar set screw.

Sometimes it may be desired to slacken up for conveniently laying off the belts, as well as to tighten them. This feature of perfect adaptation for tightening or loosening the belts has been found a most useful one in practice with this dynamometer, as the belts can always be given the necessary tightness without going beyond the most suitable conditions.

The pulleys have each a gear on the end of the hub, both of which mesh into a smaller gear between, the latter being supported on a pin made fast as a crank-pin in the arm from a shaft which passes through the centre of the hub of the cross-tree in the head of the main column. To the opposite end of this shaft the poise-bar is made fast by a set screw in a boss to which the poise-bar is secured. Thus when the small intermediate gear is thrust to the one side or the other by the large gears, the poise-bar is correspondingly moved.

It will now be readily understood that as work is transmitted from one pulley to the other through the intermediate gear on the crank-pin, the latter will be thrust to one side with a force proportioned to the effort transmitted, and that the same will tend to tip the poise-bar, to prevent which weights are applied. It is plain that the equilibrating weights on the poise-bar of a duly calibrated instrument, together with speed, etc., furnish data for calculation of the work being transmitted.

The poise-bar is graduated and has a sliding weight, called poise-weight, to move from one end to the other, and the graduations count from 0 at the middle to 10 at either end. At each end of the bar is a knife-edge pin to which is suspended a rod and foot plate, or pan, that may carry 14 or less weights of 5lb. each. Every weight is marked "5lb. = 100 foot-pounds per revolution as shifted from pan to pan."

In starting an experiment, the 14 weights, or less if preferred, may be equally divided between the opposite ends of the poise-bar, and the poise-weight may be in the middle of the poise-bar, when the latter is in equilibrium, or balanced. Now the poise-weight is moved out more and more on the poise-bar till the end is reached if not sooner equipoised by the work being transmitted. Then the poise-weight is brought back to the centre, and one 5lb. weight at the same time moved over from one poise-pan to the other, the same making a difference of 10lb. and just equal to the 10 of the poise-weight moved from end to centre. Then the poise-weight is moved out more and more again till the end figure 10 is again reached, if not sooner equilibrated, when it is again moved back and another 5lb. weight moved over, and so on. Finally, an equilibrium is found as between the poise-bar at one end and the gears at the other end of the crankshaft. Then a count of the weight will tell the number of pounds that acted to turn the poise-bar; the poise-weight being perhaps at 6, and the 5lb. weights perhaps adding up to 30, as if three weights were moved over from one side to the other. It is to be observed that each 5lb. weight moved over counts 10 in the equipoise, as by taking 5 off of one side and putting it on the other making 10 in effect.

The three weights moved over then count 30lb. and the poise-weight counts 6lb., making 36lb. in all. The work being transmitted is therefore 360 foot-pounds per revolution, the number of pounds being multiplied by 10 to give the foot-pounds per revolution.

Another way to count is to keep track of the number of weights moved over, each counting 100 foot-pounds. Then the three weights and the six on the poise-bar make in effect 3·6 weights or 360 foot-pounds per revolution.

The tables are added to illustrate the calibration and the reduction of observations made with the instrument.

Table I. shows that readings from the instrument mentioned are very readily corrected, it simply requiring 5 to be deducted.

The diagram also shows that the various results of observation plot very near to a straight line lying at an angle of 45deg., there being a close agreement between the various observations. Each new instrument should have a correcting diagram of some kind made out for itself, as the law of each instrument may differ from that of another.

TABLE I.—Giving Corrections for Readings taken from the Transmission Dynamometer in use at the Ohio State University.

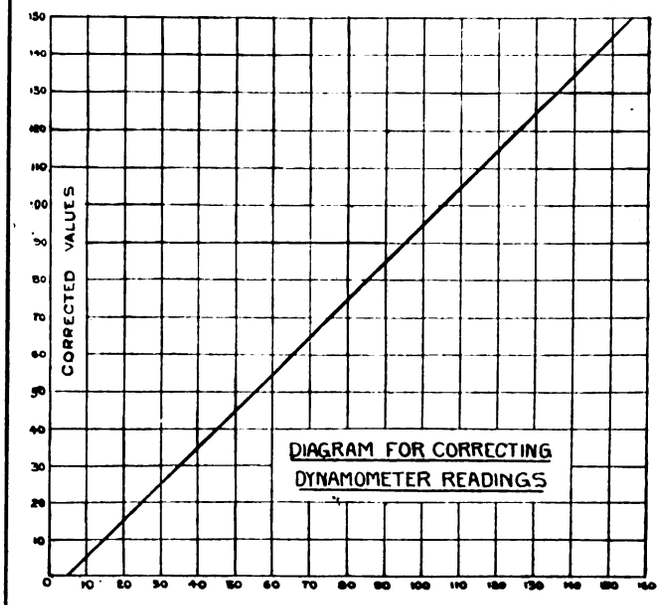

Table II. is an example of results of observations for determining the horse-power required to drive a ventilating fan of about 5ft. diameter.

TABLE II.—Power required to Drive a Ventilating Fan.

Size of fan orifice. ft.	Dynamometer readings.	Corrected dyn. readings ft.-lb. per rev.	Revolutions. per minute.	H.P to run fan.
1	310·0	305·0	336	3·11
2	285·3	280·3	432	3·70
3	259 3	254 3	444	3·40
4	127 6	122 6	328	1·22
4	214·5	209 5	450	2 86
4	224·5	319 5	440	2·93
4	256·0	251·0	460	3 50
4	254·1	248·1	490	3·68

The figures in the column of readings are the means of several readings, and hence the decimals.

The corrected readings are obtained from the Table I. above for correcting the readings of this instrument which gave these results. The Table I. shows that 5 is to be subtracted, simply from each reading, thus explaining the difference between columns 2 and 3. Hence in column 3 we have the foot-pounds per revolution of dynamometer pulley. Before correcting, we have, as readings, the figure 310, which means that three of the 5lb. weights had been passed over from one scale pan to the other, making 300 foot-pounds per revolution, while the poise-bar read 1 or 10 foot-pounds per revolution, making 310 foot-pounds per revolution as uncorrected.

But other instruments may not always give readings, the correction for which will be 5 to subtract, but some figure to be determined by calibration, similarly as was done for Table I.

Among the advantages of this instrument may be mentioned its adaptation for receiving the belts from any direction as down from above, from one side, or up from below. In each case, the most advisable arrangement is to place the cross-tree, on which the pulleys are mounted, in such position that both belts will be tightened by swinging it in one direction, or loosened by swinging in the opposite direction, the belt to take the power force to the machine to be measured being that from the pulley on the longer arm of the cross-tree. Then the belts can be adjusted any time to be just at the desired tightness without relacing, and by simply swing the cross-tree arm.

Formulæ for the dynamometer will be found useful in practice. To this end take

Digitized by Google

D = diameter of the belt pulley (driven pulley);
R = radius of gear on that pulley;
r = radius of the intermediate gear and radius of crank arm;
l = half length of poise-bar;
W = difference of weights on scale pans;
w = poise-weight, "reduced" to scale pan;
F = difference of belt tensions on driven pulley;
T = tangential component of pressure between gear teeth;
f = pressure against crank-pin;
n = number of revolutions of pulley per minute;
S = square feet of belt per horse-power per minute;
u = width of belt on dynamometer pulley;

then $$f = 2\,T = 2\,F\frac{D}{2\,R} = \frac{F\,D}{R};$$

$$f\,r = (W + w)\,l = \frac{F\,D\,r}{R};$$

$$\frac{\pi\,D\,n\,u}{S} = H.P. = \frac{F\,\pi\,D\,n}{33{,}000};$$

or, $$\frac{F}{33{,}000} = \frac{u}{S};$$

and $$(W + w)\,l = \frac{D\,r}{R}\frac{u}{S}.\ 33{,}000.$$

In the 25-h.p. instrument at the Ohio State University Mechanical Testing Laboratory, D = 14in., R = 5in., $r = 3\frac{1}{16}$in., $l = 23{\cdot}54$in., and $u = 6$in.

Then, taking the highest value of n at 1,000, and solving for S, we have

$$S = \frac{\pi\,D\,n\,u}{H.P.} = \frac{3\frac{1}{7}\cdot 1\frac{4}{2}\,1{,}000\cdot\frac{1}{2}}{25} = 73{\cdot}3,$$

giving 73·3 square feet of belt per minute passing over the pulley when the instrument is working to its highest capacity. This figure is more ample than the 60 determined by J. H. Cooper as a fair value some years ago.

The quantity of weights to accompany the instrument is

$$W + w = \frac{D\,r}{l\,R}\frac{u}{S}\,33{,}000 = 82\text{lb.},$$

as found by substituting and reducing.

Making the weights of 5lb. each and allowing 10lb. for the equivalent of the poise-weight, we find we require a trifle over 14 weights, but propose 14 as the number to go with the instrument.

In this case seven or less may be placed on each pan in starting an experiment, the poise-weight being at the centre. This collection of weights on poise-bar will serve as an efficient inertia damper to check jerky movements of the poise-bar and reduce demands upon the dash-pot.

Then, as above explained, proceed by moving the poise-weight slowly out to the end of the graduation, 10, if not sooner balanced by the power transmitted. Then move the poise-weight back to 0, and move over a 5lb. weight from one pan to the other which amounts to 10 in effect, and equals the effect of the poise-weight just returned to centre; then move the poise-weight out again to 10 if not sooner balanced; then moving it back to 0 and transfer another 5lb. weight from pan to pan, and so proceed till the balance is obtained between power and poise-bar. Then count up the weights moved over, each being counted for 100 foot-pounds per revolution, allowing the same for the poise-weight clear out, as already described in the previous example. If four weights were moved over, they would count 400 foot-pounds per revolution, and if the poise weight were clear out it would count 100, or 500 foot-pounds per revolution in all. Of if the poise-weight were at 3·7 the count would be 437 foot-pounds per revolution, etc. If running at 100 revolutions per minute, the horse-power transmitted would be

$$\frac{43{,}700}{33{,}000} = 1{\cdot}324\ \text{h.p.}$$

A THEORY AS TO THE CAUSE OF THE PHENOMENA PRODUCED BY THE RONTGEN RAYS.

BY R. C. SHETTLE, M.D.

Since the discovery of the influence of Röntgen rays in producing shadow pictures upon photographic plates and the subsequent proof that similar results can be obtained by a magnet, whether subjected or not to the influence of a live wire, quite a new importance, as it seems to me, attaches to that medium which pervades all matter and space, and which is known as ether.

Vacuum tubes are an artificial mode of producing locally and to a limited extent conditions similar to those which naturally exist between the sun and the earth; because, if lines are supposed to be drawn from the extreme confines of one of these bodies to those of the other, those lines would enclose a columnar space occupied by the so-called ether, through which the bodies in question mutually exercise the stress of gravity, variations of the magnetic needle, so intimately associated with disturbances of the solar photosphere, the phenomena of light, etc., whilst the phenomena produced by the Röntgen rays are for the most part the product of discharges of electric force through the vacuum tube.

The present state of our knowledge of the ether, and of its relations to masses of formed matter, does not appear to give any clue to a satisfactory explanation of the above-mentioned natural phenomena, or of the Röntgen rays phenomena; but I venture to think that when consideration is given to the theory which I published in 1894 as to the formation of matter and the nature of the ether all mystery will vanish, not only as to the mode in which gravity was brought into existence, but also as to the real nature of the ether and its relations to the Röntgen phenomena.

To explain this, I would briefly describe the principles involved in my theory of the nature and cause of gravity. I assume: (1) That prior to the formation of matter space was occupied by a dense homogeneous stuff, every portion of which was in absolute contact with adjacent portions, and, therefore, throughout subject to a uniform degree of cohesion. (2) That matter resulted from the segregation of portions of the original stuff, and cohesion having been destroyed around such portions the force would continue to act from all points on the surface towards the centre, causing the segregated portions to condense and assume a spherical form. (3) That each of these portions, in proportion to the quantity of the stuff which it contained, would by action and reaction (or stress) attract other portions which condensation had separated, but with which they were more or less closely associated. We thus perceive the mode in which the force of cohesion, or force of absolute contact, gave origin to the force of gravity, or force acting at a distance. Rotation of the segregated masses would result as a consequence of the stress, and the spherical would give place to the spheroidal form. (4) That variations in the density of the formed matter would result from the quantity of stuff which entered into the composition of each material unit, because the force of cohesion appears to be capable of indefinite extension. (5) That polarity, or a particular description of axial rotation, would also be determined by the quantity of stuff undergoing condensation. (6) That the now existing ether is simply the residue of the original stuff, its increased tenuity having been acquired by the quantity of stuff condensed from a given volume, and the stress which the condensed matter exercises upon it from opposite points. (7) That as each material unit undergoing condensation would act like an exhaust engine upon this residuum, the atomic surfaces would be coated with a film of this unformed homogeneous stuff, the density of which, would, as the density of the matter itself depend upon the quantity of stuff condensed into that particular unit, which stuff, or ether, in accordance with the opinion of Fresnel, should travel with the matter.

Upon the principles embodied in my theory I have thus shown the relations which exist between formed matter and the forces of cohesion and gravity, and also that the space existing between any two masses of matter must be traversed with lines of stress having certain well-defined relations to and connections with the material atoms which create them. It is therefore equally certain that when two masses of matter, such as the sun and the earth, are rotating axially, whilst each is subject to the attraction of the other, incessant change in the direction of any particular line of stress would occur with every change in the density of the chain of atoms throughout the mass causing such stress. It is further suggested that such changes must originate a vibration in the contiguous ether, which vibration is continued through space. These vibrations have a very important bearing upon the production of electric and magnetic force in our earth.

Turning now to the Röntgen or other tubes of a like nature, we recognise (1) that we have to deal with an artificial vacuum more or less complete according to the degree of exhaustion;

Digitized by Google

(2) that the now well-known phenomena are produced when electric force passes through the tube—*i.e.*, that images of dense bodies, in proportion to their density, can be transmitted through perfectly opaque bodies and be impressed upon photographic plates.

Unquestionably this electric force is always the result of the association, under certain conditions, of dissimilar electric bodies, and the force is in proportion to dissimilarity plus the quantity of matter so associated. In other words, the electric force or stress is the direct effect of so connecting two dissimilar forms of matter that they mutually act and react or exercise stress upon each other. The primary effect of this stress, in proportion to its extent, is to disturb equilibrium in the surrounding media by causing the axes of contiguous atoms to face in accordance with the polarity of the stress-creating bodies. The secondary effect is locally to divert the ether from its accustomed interatomic channels into those which more readily admit of its flow, channels which have been opened up, so to speak, by the poles of the atoms all facing one way,* with the result of causing the relative currents of ethereal stuff derived from the motion of the earth through its sea of ether to pass between the two bodies, or, for the time being, electric poles. Consequently, the force passing through the Röntgen tubes, owing to the highly attenuated state of the matter therein contained, acts upon and gives a definite polar arrangement to the atoms of all surrounding matter, which polarity is more especially in the direction of the force.

Hence it appears to me that the Röntgen rays are capable of producing images of bodies, by which they have been influenced, even through opaque matter of less density, such as the non-actinic paper or other substance effectually protecting the photographic plate from light.

The images which I have obtained of magnets, and of the paper by which they have been affixed to the back of photographic plates, are now capable of explanation, because the fact is recognised that wherever the magnets are placed their stress (or action and reaction) exists between the artificial magnetic force and the terrestrial magnetic force. In fact, in proportion to the potential of the artificial magnet and the direction which its poles take with regard to the terrestrial magnetic poles, there is local disturbance—*i.e.*, increase or diminution of the force in the natural and artificial magnets—which disturbance, as to superficial extent or area, necessarily corresponds with the superficial area of the magnet or pieces of paper by which the magnet was kept in position, leading to such disturbance. For example, a sensitive photographic plate within a dark shutter, and lying horizontally, is permeated by rays of force passing from the earth to some planet, or to the sun, such plate receives no image. Let a magnet lie outside, whether above or below, and in a perfectly dark room, as used by a photographer, this magnet disturbs the passage of the rays of force. After a short time the plate on development shows the image of the magnet.

Or, let rays of force radiating from a Röntgen tube be similarly interrupted, they too produce an image in whose production I maintain the light, or what we call light, plays no effective part in image production, but is an incidental or extraneous phenomenon necessarily connected with the passage of the electric current between the poles within the tube.

THE UTILISATION OF WATER POWER, ESPECIALLY WITH A SMALL FALL, WITH SOME EXAMPLES OF PLANTS FOR THE GENERATION OF ELECTRICAL ENERGY.†

BY ALPH. STEIGER.

(Concluded from page 607.)

Assuming that the water power available at Brantham Mills were applied for the generation of electric energy, it would, in the first instance, be necessary to obtain a conveniently high speed to drive an electrical generator without much intermediate gearing. A turbine similar to the one actually working could be made for exactly these conditions, running at 30 revolutions per minute, and a pair of bevel wheels put in of such proportions as to give the first motion shaft a speed of 150 revolutions per minute. This speed would be very suitable to drive a dynamo of 40 h.p. by means of a belt or ropes. A higher speed of the turbine than 30 revolutions would, for such a low fall, only be obtainable at the expense of efficiency. As in this special case the fall, and consequently the power, varies with the rise and fall of the tide, the full power of the turbine can, of course, only be relied on during 15 or 16 hours every day. The power produced during the time when the fall is diminished beyond the limit at which it is 40 h.p., and at less than the normal speed, could probably be applied to charge electrical accumulators. The construction of the turbine shaft deserves some notice. The space underneath the turbine being always filled with

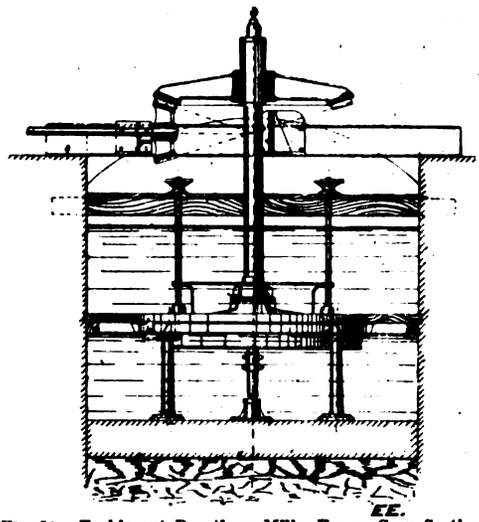

FIG. 5A.—Turbine at Brantham Mills, Essex—Cross-Section.

water, and, therefore, inaccessible, the pan for the footstep is placed on top of a column round which the hollow cast-iron shaft revolves. The upper part of the turbine shaft is widened, and contains an adjustable steel pin which revolves in the pan or cup, filled with oil. Although a well-constructed footstep

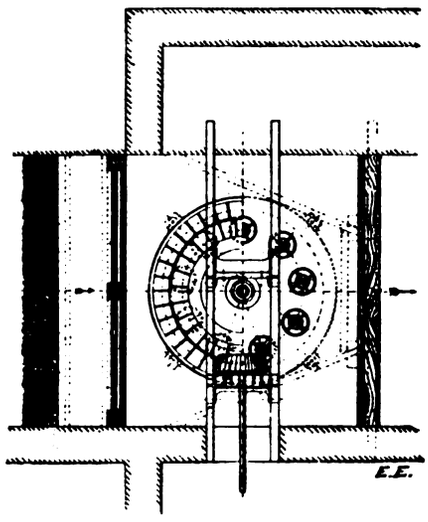

FIG. 5B.—Turbine at Brantham Mills, Essex—Ground Plan.

will last for years without requiring repairs, an easy access to it is of great advantage. Similar turbines were erected by me in other mills near Norwich, Reading, and Lewes. In all cases the fall varies between (23in.) 2ft. 6in. and 6ft., the reduction of the fall being caused by floods, while the water supply varies

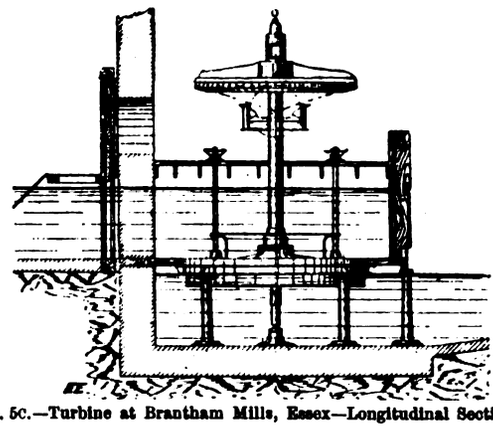

FIG. 5C.—Turbine at Brantham Mills, Essex—Longitudinal Section.

in the proportion of about 1 to 4. In each case the local conditions were carefully investigated and the turbine constructed accordingly. The good results obtained in each case are due to the careful adaptation of the turbine to the conditions. The importance of a careful consideration of local conditions is evidenced by several failures which were recently brought under

* The analogue of this is found in the behaviour of soft iron when subjected to the influence of currents of electricity circulating around it.

† Paper read before the Institution of Electrical Engineers, May 28.

Digitized by Google

my notice. In one of these instances, the turbine—which in itself is a very good motor—gives very poor results owing to the disregard of the actual conditions of the locality. Even the construction of some details of a turbine depends sometimes on these conditions, and in several cases now under consideration I have had to depart from the general practice of designs of turbines, in order to secure the highest results when most required. How varied the construction of a Jonval turbine may be will be shown by the following examples.

The turbines of the Geneva Waterworks, built by Messrs. Escher, Wyss, and Co., of Zurich, work under a maximum fall of 12ft. during the winter season, when the water supply is shortest, while during the summer season the water supply stored up in the mountains, in the shape of snow and ice, is abundant. The large summer supply reduces the fall, however, to 5ft. 7in. The power of each turbine, of which there are now 17 at work, is 210 actual horse-power, and they run at a uniform speed of 36 revolutions per minute, whether the fall is 5ft. 7in. or 12ft. The cost in this case was a secondary question, the turbines have, therefore, been provided with the best possible arrangements to suit the large variations of the fall and quantity of water. The drawing shows three concentric rows of buckets. The outer row alone will develop 210 h.p. under the maximum fall of 12ft.—its outside diameter is 14ft. Each of the two inner rows of buckets is provided with a revolving gate, working separately. Each turbine drives a pair of double-acting plunger pumps direct, the crank common to both pumps being fixed on the vertical turbine shaft.

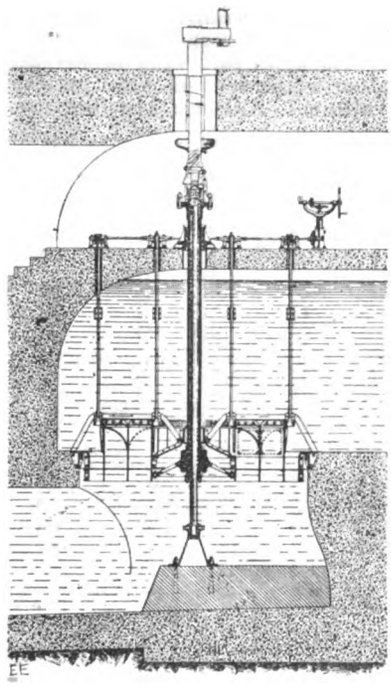

FIG. 6.—Turbines of the Waterworks, Geneva.

An interesting turbine installation, under a fall varying from 10ft. 9in. to 8ft. 10in., in connection with electrical generators, is that at Baden, in Switzerland. It was described in *Engineering* of November 1, 1895. This plant was erected to supply the town of Baden with electric light and the necessary driving power to the new works of Messrs. Brown, Boveri, and Co., the well-known electrical engineering firm. The fall had to be created by a weir and a canal about 2,500ft. long, which added considerably to the cost of the plant. Each of the three turbines is of the Jonval type, giving off 200 b.h.p. It is impossible to build a turbine of that power for the fall available in this case which would run with a speed high enough to drive a generator direct. The turbines run at 40 revolutions per minute, which speed is maintained under the varying fall by means of gates for the inner row of buckets. The generators—two-phase dynamos of the horizontal type, made by Messrs. Brown, Boveri, and Co.—run at 200 revolutions per minute, and are driven direct off the turbine shaft by means of a pair of bevel wheels. The exciter dynamos, of which there are three, of 10 h.p. each, are driven each by a separate turbine. These small-power turbines naturally run at a higher speed—namely, 180 revolutions per minute—and drive, therefore, the exciter dynamos without any intermediate gearing. In most cases in this country where a good water supply is available, the fall will be rather lower than 10ft. or 12ft.; it will therefore require intermediate gearing to drive a high-power generator, and it will even not often be possible to connect it direct with the first main shaft driven off the turbine by bevel wheels. Belt drives are very convenient to get up the necessary speed of dynamos, but for large power they are very expensive, and absorb a considerable amount of the power in friction. The ordinary round hemp and cotton rope is objectionable, on account of requiring frequent repairs and resplicing. During an inspecting tour in Switzerland last summer, I came across a new kind of hemp rope, which seems to supply just what is wanted to drive large-power dynamos. A piece of this patent rope is here for inspection. It is a plaited rope of extreme pliability, which does not stretch. I found this rope working at the generating station at Schaffhausen. The power at the generating station is transmitted from the countershafts, driven off two turbines of 300 h.p. each by means of bevel wheels, on to the generators by means of 10 such ropes, 1¾in. thick. The rope pulleys on the dynamos have a diameter of 5ft., running 300 revolutions per minute. The rope pulleys on the countershaft have a diameter of 13ft. 6in., and the distance between the centres of shafts is 51ft. The power is electrically transmitted to a spinning mill about half a mile distant from the generating station. The secondary station consists of an electromotor of 200 h.p. coupled directly to a main line shaft, and two electromotors of 190 h.p. each coupled together. The latter, running at 300 revolutions per minute, carry a rope pulley of 5ft. diameter with 14 grooves. One hundred horse-power are transmitted by four such ropes to a shaft 21ft. above the electromotor at an angle of 51deg., while the remaining 250 h.p. are transmitted to another shaft on about the same level and 17ft. 8in. distant, running with 130 revolutions per minute. In spite of the unfavourable relative position of the shafts, these ropes work with extreme regularity and easiness, and their adaptation has, according to the manager of the spinning mill, put an end to the trouble and frequent stoppages caused by the breaking of the round ropes which were previously used.

Returning to the description of water-power plants proper, two more examples in connection with the generation of electricity deserve to be mentioned, showing how certain objects can be attained by a special construction. One of these is the installation of five new turbines for the aluminium works at Neuhausen, on the Rhine Fall, in Switzerland. One of these turbines is here illustrated. Each of these turbines gives off 610 b.h.p. under a fall of 66ft., with a quantity of water of 6,500 cubic feet per minute. With the high fall, a high speed suitable for driving the dynamo direct is naturally obtained—

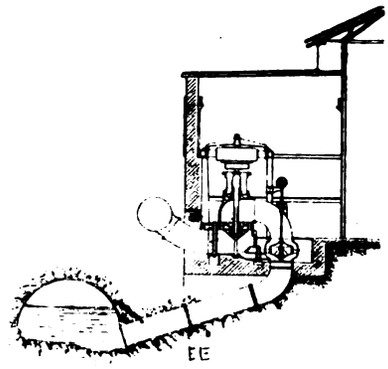

FIG. 7.—Turbines of the Aluminium Works at Neuhausen, Switzerland.

an arrangement which has also been adopted in this case to economise space. On the other hand, the load on the footstep of a turbine of the power mentioned by the pressure of the water, in addition to the weight of the armature of a generator of corresponding dimensions, is so great that a special arrangement had to be adopted to release the footstep of at least a part of that load. In order to overcome this difficulty, the turbine has been reversed, the water passing through the turbine upwards, acting, therefore, in the opposite direction to the weight of the machinery. The boss of the turbine wheel is, moreover, formed into a piston, working in a cylinder, to which water under the pressure corresponding to the fall is admitted, thus counteracting again the weight of the moving parts of the turbine and dynamo. The water, after passing through the turbine, is conducted to the tail-race through a suction tube, the turbine being placed 15ft. 9in. above the tail water. It runs at 150 revolutions per minute, and is a single Jonval turbine. To regulate its speed, if required, a ring gate is inserted in the suction tube, while it can be stopped by a throttle-valve in the wrought-iron tube taking the water to the turbine. The total power now utilised by these aluminium works is 4,550 h.p. The turbines were constructed by Messrs. Escher, Wyss, and Co., of Zurich, and the dynamos by the well-known electrical works at Oerlikon. Each dynamo is of 7,500 amperes and 55 volts.

The last turbine installation here illustrated is that at Zufikon-Bremgarten, also in Switzerland. The drawing shows another arrangement to counteract the weight carried by the footstep, and at the same time an arrangement by means of which the necessary speed to drive a dynamo of large power

Digitized by Google

direct under a medium fall is obtained. The plant consists of four sets of double Jonval turbines of 325 b.h.p. each, running at 115 revolutions per minute, and a smaller Jonval turbine of 34 b.h.p., driving two exciter dynamos, running with 210 revolutions per minute, and was erected to supply electric light to the neighbouring town of Wohlen, and driving power to the new works of Messrs. Escher, Wyss, and Co., in Zurich, and a large flour mill close by these works. The distance over which this power is transmitted is about 11 miles. The fall is 17ft. 6in., and was obtained by building a dam across the River Reuss, and a tunnel about 1,100ft. long across a hill round which the river flows at a rather high speed. The water is divided between two Jonval turbines fixed on one common shaft so that it passes upward through the lower wheel and downwards through the upper wheel. By distributing the water in this manner, the diameter of each turbine is reduced, and the speed consequently increased. At the same time the pressure of the water, which would otherwise act on the footstep, is entirely counterbalanced. The central part of the lower wheel is, moreover, formed into a disc, on which the water presses from below, releasing the footstep also partly by the weight of the revolving parts of the turbine and the dynamo. The space between the two turbines on each shaft is connected with the tail-race by a flume formed of concrete, which acts as a suction tube. This turbine plant was also erected by Messrs. Escher, Wyss, and Co., and the dynamos were built by the Oerlikon Works.

The examples given above of the utilisation of water power may be considered as representative types of successful installations under different conditions. They are sufficient in number and in variety to prove the necessity of a selection from motors which are different in principle, and of the careful adaptation of the turbine selected to the local conditions and requirements. A turbine installation under a low fall will be more costly than one under a higher fall; it is consequently of special importance to obtain the highest possible efficiency, even at an extra expense, under a low fall. The cost of the turbine itself

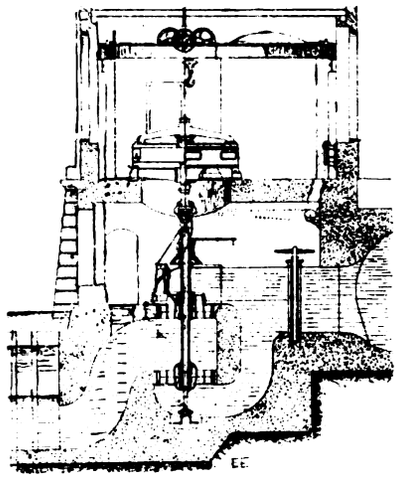

FIG. 8.—Turbines at Zufikon-Bremgarten, Switzerland.

is only a fraction of the total outlay for the plant, including foundations, connection with the machinery to be driven, and sometimes a weir and a canal. The cost of these permanent structures exceeds that of the motor; it is therefore a penny wise and pound foolish policy, after putting in the permanent structure, to try and cut expenses by putting in a turbine of insufficient capacity or inferior efficiency. The commercial value of a water power depends rather more on the annual outlay on the same than on the first cost, and the annual outlay for the work obtained from the power is the smaller the higher the efficiency of the plant. The efficiency of a turbine which can be obtained and honestly guaranteed, even if the fall is low, is about 75 per cent. Eighty per cent. and a little over is sometimes obtained under favourable conditions, and has been proved by careful tests made by responsible experts; but an efficiency of 85 and 90 per cent., sometimes claimed, is never reached if the quantity of water be accurately measured during the test. If the efficiency of the turbine is guaranteed at all, it should be stated not only for the most favourable conditions but also for a reasonable minimum of the fall or the quantity of water.

In many instances within my own knowledge, water power, in itself sufficient to drive the machinery of a factory, but improperly utilised, is supplemented by artificial power, produced by steam, gas, or oil engines. The loss of money caused by the waste of the cheap power from a running stream in this manner amounts certainly to a big sum in this country alone. The annual cost of such auxiliary power, calculated for 3,000 working hours, may be put at three to four times the cost of water power, and calculated for 6,000 working hours, four to eight times the cost of water power. A judicious utilisation of the water power in such cases would not only result in an enormous saving of money, but in a gain of a large amount of power now unutilised. Most factories are closed at night time, when the water is allowed to run away without being made use of. Assuming that the water power is insufficient to drive all the machinery in the daytime, while it is wasted during the night, electrical storage batteries in connection with a generator might very advantageously, and perhaps with greater economy, be used instead of auxiliary steam, gas, or oil engines. It seems probable that in the near future the electrical transmission of power will take the place of shafting and belt drives in factories, when certainly the waste of water power would be prevented in the manner suggested. Owners of factories driven by water power might even find that by improving their water power they obtain spare power which could be profitably applied by the generation and distribution of electrical energy in the immediate neighbourhood.

I may add that the majority of large-power central stations now being erected in Switzerland for the generation and distribution of electrical energy are mostly utilising small or medium falls varying between 10ft. to 30ft. The storage of water in the shape of snow and ice on our mountains provides us with a good water supply during the summer, but the low temperature in winter reduces that water supply very considerably. The water power there is just as variable as in other countries, and those falls which can be advantageously utilised on account of being situated in the inhabited and industrial districts are often not any higher, or not much higher, than in this country; the only difference being that such small falls occur more frequently, rendering a concentration of large power in one place easier, and perhaps less costly. Still, it is my conviction that concentration of water power for the distribution of electrical energy, or for the generation of a large amount of electric current, as required for electro-chemical and electro-metallurgical processes, is possible in many places in this country without going into prohibitive expenditure for canals, etc.

In conclusion, I hope to have succeeded in my endeavour to show how water power under low falls can be, and is, very advantageously and economically utilised for the generation of electrical energy, and that a very large amount of water power is now running to waste which could, in conjunction with electrical machinery and apparatus, be turned to profitable account by such a hearty co-operation of the electrical and the water-power engineer as has resulted in such success of commercial enterprise in my native country.

DISCUSSION.

Mr. Tremlett Carter opened the discussion. Mr. Steiger had promised to prove the utility of small falls, and he (Mr. Carter) failed to appreciate the logic of introducing examples of large falls of 300ft. or 350ft. The only really small fall described was the Brantham one, where they had a turbine running at 24 revolutions a minute. That would not be at all suitable for driving a dynamo. England was admittedly a country of small falls, and those of a character which were liable to suffer from two very bad complaints—namely, too much water and too little water. He had in his mind a mill site he had seen, which under ordinary circumstances looked a highly desirable one, but with only a little extra rain the mill race—in fact, everything was completely under water. Moreover, in most English rivers the millers were in possession, and pounded up the river when they were not working, so that it was impossible to get a regular flow. He was familiar with a little electrical generating station driven by a water-wheel, with stand-by engines, which had to run charging accumulators in the daytime for the night load, because at night a miller just above shut back all the water, so that there was no river at all when it was most wanted. Another objection to a low fall was the quantity of water to be dealt with, and the difficulty of governing when there was such a mass of water to be dealt with. It was wrong to say, as had been done, that such and such a type of turbine was adopted because the dynamo required to be run at a certain speed. Dynamos could be built to suit the best speed for the turbine. The partial admission system amounted to having several turbines, of which only one might be at work. He thought reaction turbines were to be preferred unless the fall was exceptionally high, as in the Comstock lode. Water power might be the free gift of Nature, but there seemed to be frequently a legacy duty of 100 per cent. to be paid in order to get it.

Mr. Alexander Siemens remarked that the case of Brantham required careful consideration because it was necessary to eliminate the complication introduced by the periods of high water, which occurred at a different time every day. The possibility of using water power in connection with electric machinery had not been passed over in this country. Nearly 20 years ago—he could not at that moment remember the exact date, but it was before the invention of the incandescent lamp—Lord Armstrong had used water power for the electric lighting of his picture gallery. Then there was the case of Godalming. In 1881 the streets of that town were lighted electrically by water power from a mill with a low fall. Godalming was the first town in the world to light its streets by electricity in this way. Unfortunately, the thing was before its time, and was not a financial success. He agreed with Mr. Carter that in England it was impossible to rely upon your water supply.

Digitized by Google

Therefore, it was necessary to have a stand-by plant. The double expense destroyed the economy, and it was better not to complicate the plant by the addition of the water power.

Mr. Shoolbred, as an example of the utilisation of water power by turbines, referred to the case of Menier's chocolate works. The fall varied from 5ft. 6in. to 15in., and the whole of the River Marne had to be dealt with. He thought the impulse turbine should not be put on one side entirely. Most of Mr. Steiger's examples had been confined to turbines of the Jonval type. He would remind them that there was a well-known reaction turbine in this country—the "Thomson" inward-flow—the inventor being the late Prof. James Thomson, the brother of Lord Kelvin.

Mr. M. Mowat gave some particulars of a large turbine plant used by his firm for driving two cotton mills in India. It was probably the largest water-power plant in the Queen's dominions. They had at present eight turbines of 250 h.p., and hoped ultimately to work up to 4,000 h.p. By using water power they were able to give the proprietors a better return than they otherwise would if they had to burn coal. Power was transmitted from the turbines to the mill—an eighth of a mile—by means of wire rope, which worked admirably. The waterfall utilised is at Gokak, on the Ghataburba river, Southern Mahratta country, India.

The **President** said that as Mr. Steiger had to reply, and the meeting could not be adjourned, any further observations must be handed in in writing to the secretary.

[Among the observations handed in were some from **Mr. W. Geipel**, who remarked that Mr. Steiger recognised the difficulties in utilising low falls due to variations in head and quantity—in the one extreme there was all head and little water, while after heavy rain there was abundance of water and little head; and between these two limits all degrees depending upon the proverbially variable British weather. Mr. Steiger proposed to meet these difficulties by subdividing the turbine into several compartments. It might be that in some cases this was a good arrangement; but from his experience in the use of water power for electric lighting purposes, he found that the varying load on the dynamo must be considered in addition to the difficulties of the varying water power. It was also to be remembered that a turbine had a critical speed at which the best efficiency was obtained, and that this critical speed varied with the head of water; whereas, on the other hand, the dynamo required one constant speed. It was frequently preferable therefore to subdivide the water power and use several turbines, each driving its own dynamo. These turbines should be arranged for working at different heads—one should be for the maximum head and of suitable size to use only the minimum quantity of water available under that condition, the second should be suitable for a less head and larger quantity of water, and so on. The number of these units would of course be governed by the conditions. An additional advantage of the method is that repairs may be effected to one unit whilst others maintain the supply. This system might not be economical in all cases, especially where the maximum available power is small, but in many cases it would give a very much better all round efficiency than the compound turbines referred to by Mr. Steiger. There was a more important point only briefly referred to by the author which was not dealt with by any of the speakers, and that was the question of first cost. Mr. Steiger said, "The commercial value of a water power depends more on the annual outlay than on the first cost." On this point he (Mr. Geipel) was directly at variance with the author, as he had always thought that the annual outlay on turbines was almost negligible, and that the only other consideration was first cost. If that item was also negligible, why then the millennium of those gentlemen who regularly promote in the public press the utilisation of the tides was indeed at hand. It was unfortunately this very question of excessive first cost which made the power produced by the low waterfalls derivable from tides so much more expensive than that from steam or other engines. The importance of first cost was being daily driven more closely home to the minds of all electrical engineers, and for that reason it was to be regretted that the paper contained no information whatever upon this important point. The use of storage batteries for storing the power during periods when the power is not required was well known, but he (Mr. Geipel) had in several cases found it cheaper to construct a water reservoir to effect the same purpose. With regard to the difficulty experienced by the author with round ropes, Mr. Geipel thought he must have got hold of a very bad quality of round rope. With good English-made round ropes there would be no hesitation in transmitting more than double the power stated.]

Mr. Steiger, in replying, said he must contradict the statement of Mr. Carter that impulse turbines were only suitable for very high falls, say 1,000ft. The impulse turbine was suitable for any fall, from 3ft. upwards, where the fall was constant, and they had the advantage of being able to be regulated according to the quantity of water without loss of efficiency. If the law permitted a miller in shutting off the water in the way described—well, in every country in which water power was appreciated it did not, but prevented the water being shut off from the user below when the user above happened not to be using it. Automatic governing with very low falls was not more difficult than with very high ones. In the latter case the difficulty was that a trifling movement produced a large difference in the power. As a matter of fact, with reference to the question whether the turbine or the dynamo should determine the speed when it was desired to use large dynamos directly coupled to the shaft, the turbine maker was often asked by the dynamo builder for a particular speed and endeavoured to supply it. It was not a fault of water power if people expected too much of it, or when the minimum water supply corresponded to 100 h.p. they put in a dynamo plant that wanted 150 h.p. He would remind Mr. Shoolbred that he had pointed out in his paper that it was the variation of water-level to which most low falls were liable that determined the type of turbine. A reaction turbine would be preferable for working a dynamo under a low fall, because of its higher speed, especially if the tailwater level varied. With reference to Prof. Thomson's vortex wheel he believed it was efficient enough at full gate, but he did not know what the efficiency was at part gate. It was a pity that more practical tests had not been made with various types of turbines, for some for which high results were claimed had proved in practice very disappointing. The efficiency under various conditions should be stipulated for.

Major-General Webber proposed the vote of thanks to Mr. Steiger for his paper. Without using the opportunity to get in a speech on the subject, he wished to disagree with the attitude of Mr. Carter on the subject. Mr. Steiger's paper could not be a full exposition of the subject, but was eminently suggestive, and would induce many of them to go into the question of water power. So far as his experience went, he might say that he had inspected many water powers with low falls in various parts of the country, and he believed that there were many instances in which it was worth while to investigate its use.

Prof. Silvanus Thompson seconded the vote of thanks, and remarked, with reference to what Mr. Shoolbred had said about the turbines at the Menier works, on account of the diminution of the fall in times of flood it had been necessary to put in an undershot waterwheel to meet such occasions.

The list of candidates balloted for and elected at the commencement of the meeting was given, as usual, in our last week's issue. This being the last meeting of the session, the list which was passed for the next ballot (which in the ordinary course would have been taken in a fortnight) had to be dealt with before the adjournment. The following therefore were balloted for and elected at the close of the meeting: Dr. Alvaro de Vilhena, vice-director of the Brazilian Government telegraphic department (foreign member); A. H. Howard, 39, Victoria-street, S.W. (member); E. J. Cruiser, 73, Merrion-square, Dublin; J. Gray, University, Glasgow; T. Rungay, Blenheim Palace, Woodstock; G. E. Piggot, 110, Cannon-street; and Sidney Weiss, Harbour-road, Edgbaston (associates); and W. Steuart, 1, Girdler-road, Kensington (student).

MUNICIPALISATION OF TRAMWAYS.

For more than a year a special committee of the Manchester City Council have been considering the subject of the tramways of the city and the desirableness of putting them entirely under municipal control. The committee have now issued their report, in which they give information as to the cost, results, and manner of working tramways by the Corporations of Glasgow, Blackpool, Plymouth, Leeds, and Huddersfield, and of which the *Birmingham Daily Post* published the following abstract:

In Glasgow, on August 1, 1895, the result of the first 11 months' working of the tramways as a Corporation department, showed that the gross revenue had been £226,414. 3s. 4d., and the gross expenditure £202,209. 9s. 2d. This left a credit balance of £24,204. 14s. 2d., from which the sum of £9,193. 19s. 7d. had been written off capital account as depreciation, £6,750. 9s. 1d. had been placed to reserve fund for renewal of permanent way, and £8,260. 5s. 6d. had been paid to the common good. This payment to the common good—fixed by the Town Council at the rate of £9,000 per annum—was in lieu of the former net revenue of the common good from the tramways, the exact average annual amount of which during the 23 years of the lease was £2,766. 8s. 9d. In Huddersfield there had, from 1882 up to last year, been an annual deficiency, amounting in all to £41,238, which had had to be provided for out of the rates. The Leeds Corporation had acquired the tramways in that city too recently to give valuable information; at Plymouth there had been a loss, but the growth of income and diminution of expenditure were gradually tending to bring the undertaking up to paying point, whilst at Blackpool there was a record of profit. The committee go on to say: "The principal arguments in favour of the 'municipalisation' of the tramways appear to be as follows: (*a*) The tramway system is a public necessity and a monopoly, and, as such, should not be used to put large dividends into the pockets of shareholders. (*b*) The tramway service might be worked better from a citizen's point of view as opposed to the point of view of shareholders—for instance, 'through routes' might be arranged for, the present lessees having always opposed the adoption of 'through routes.' (*c*) The dividends now paid to the shareholders would be paid into the public purse. (*d*) The policy hitherto adopted by the Manchester Corporation has been in the direction of working and entirely controlling all undertakings of a municipal character—*e.g.*, gas, water, electric light, and hydraulic power. The principal arguments against the 'municipalisation' of the tramways appear to be as follows—viz.: (*a*) If the general tramway system of the district were 'municipalised' in either of the two ways already mentioned, the responsibility attaching to Manchester would be very great. We should have a municipality or municipalities working a tramway system much greater in dimensions than any other tramway under

Digitized by Google

taking in the country, and the information as to what has been done in other towns does not furnish encouragement for the Corporation in this direction. (*b*) Various difficulties in the way of 'municipalisation' of the general tramway system of the district present themselves, by reason of the expiration of the various leases and the power of the various local authorities to purchase the tramways owned by the Manchester Carriage and Tramways Company within their respective districts not being synchronous. (*c*) The ramification of the tramway system into districts outside the city boundary, and the fact that many of the lines are not owned by the local authorities places Manchester in a more difficult position than Glasgow was in. In Glasgow the tramway system is entirely contained, with two slight exceptions, within the city boundary, and the whole system (including the exceptions referred to) was constructed and is owned by the Corporation. (*d*) The tramcar service which has been provided by the lessees of the lines in Manchester has been an excellent one from almost every point of view. The tramcars themselves will bear favourable comparison as regards comfort, cleanliness, and general appearance with those of any other city in the kingdom. The lessees have met the requirements of the community by the adoption of penny stages on all the routes. (*e*) From a financial point of view the lease of the lines has been satisfactory. The Corporation accounts at March 31, 1895, show that the rents received from the lessees have enabled the Corporation to pay off practically all the loans, to pay for all ordinary repairs of the lines, and for the renewal of a number of them, and to pay a total sum of £70,911. 12s. 9d. to the city fund in aid of the rates. (*f*) At the close of the 23 years during which the Glasgow lines were leased to the Glasgow Tramways Company, the financial statement of that Corporation shows that the total amount of net revenue paid to the 'common good' was £63,628. 1s. 1d., and there was still a loan debt owing of £143,495. 16s. 11d. During the period which the Manchester leases have run (say, 15 years) the total amount of net revenue paid to the city fund has been, as stated above, £70,911. 12s. 9d., and the loan debt owing on March 31, 1895, was £16,593 only. (*g*) In the case of Glasgow it was not until after the failure of the negotiations between the Corporation and the lessees of the lines for a renewal of the lease on terms satisfactory to the Corporation that the Town Council decided to work the tramways themselves. The necessity, therefore, of 'municipalising' the tramways in that city may in a measure be considered to have been forced upon the Corporation. If the action of Glasgow is to be a guide to Manchester, it would appear desirable, therefore, for the Corporation in the first instance to approach the present lessees with a view to a renewal of the lease on terms satisfactory to the Corporation, and, in the event of such negotiations failing, then, and not until then, should the question of 'municipalisation' be entertained. (*h*) If it be arranged, as has been suggested, that the leases which expire in 1898 be extended at existing rents so as to be coterminous with the main lease, which expires on April 27, 1901, ample time will then be afforded for the consideration by the Corporation of the various kinds of tramway traction, other than horse traction—*i.e.*, cable, steam, underground and overhead electric traction—and it appears probable from the developments which are now taking place, and the experience which other towns are gaining in regard to mechanical traction, that this Corporation will, when the subject is taken in hand by them, have sufficient evidence to enable them to come to a conclusion in the matter. (*i*) It may also be pointed out that by making the leases coterminous in 1901, ample time will be afforded for forming a more correct judgment than can be made at the present time of the financial results of the working of the tramways in Glasgow and other towns." In conclusion, the committee report that after full consideration of the subject referred to them by the resolution of the City Council, they are of opinion that it is desirable to allow the matter to remain over until nearer the termination of the first lease, which will expire on May 1, 1898, and the Corporation should make application to Parliament for powers themselves to work the tramways of the city. The committee also recommend that this subject be left in the hands of the Paving, Sewering, and Highways Committee, by whom the tramways of the city were constructed, and who have in their possession all necessary information.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MUNICIPAL ELECTRICAL ASSOCIATION.

SIR,—I send herewith advance proof of programme of the first annual meetings of the association, which will be held in London on Wednesday, Thursday, and Friday, the 10th, 11th, and 12th inst, and also enclose card for your representatives.

Copies of the papers are to be sent out in good time before the meetings, at which short abstracts only will be read in order to facilitate the discussions, but in order that the interest of these discussions shall not be prejudiced by premature publications the committee have considered it desirable to copyright the papers in the name of the association.

This has been done, but should you see fit to publish all or any of the papers on any date after the 15th inst. you have full liberty to do so.—Yours, etc.,

WM. L. MADGEN, Hon. Secretary (*p.p.* G. J. S.).

117, Bishopsgate-street, E.C., June 1, 1896.

[The above letter, together with the programme referred to, reached us this week. The honorary secretary of the Municipal Electrical Association in kindly forwarding us the "advance proof" from the office of the contemporary with which he is connected has not acted with his usual business-like promptitude. This "advance proof" was sufficiently advanced to appear complete in our contemporary's columns on May 21. We also notice that publication of the papers in our columns on the 12th inst. would be premature, and would prejudice the discussion on the papers which are read on the 10th and 11th inst. respectively. Why?—ED. *E. E.*]

MUNICIPAL ELECTRICAL ASSOCIATION.

FIRST ANNUAL CONVENTION.

PROGRAMME.

WEDNESDAY, JUNE 10.

General meeting for the discussion of papers.—Royal United Service Institution, Whitehall, S.W. 10.15 a.m.

President's address: "The Municipal Electrical Association and its Objects."

Papers for discussion: (1) "Electricity Supply at 220 Volts," by A. S. Barnard, borough electrical engineer, Hull. (2) "Alternating-Current Stations and High-Voltage Lamps," by Harold W. Couzens, borough electrical engineer, Taunton. N.B.—Paper Nos. 1 and 2 will be taken together for discussion. (3) "The Control by Municipal Authorities of Consuming Devices and the Wiring connecting them to the Mains," by C. H. Wordingham, city electrical engineer, Manchester. (4) "Electricity Works Records," by A. B. Mountain, borough electrical engineer, Huddersfield.

Adjournment. 1 p.m.

Visit of inspection to the works of the London Electric Supply Corporation, Limited, Deptford. Chief engineer, Mr. P. W. D'Alton. 4 p.m.

THURSDAY, JUNE 11.

General meeting for the discussion of papers.—Royal United Service Institution, Whitehall, S.W. 10.15 a.m.

Papers for discussion: (5) "The Cost of Electricity Supply," by Arthur Wright, borough electrical engineer, Brighton. (6) "Cable Specifications and tests," by Joseph A. Jeckell, borough electrical engineer, South Shields. (7) "The Organisation of an Electricity Works Staff," by E. T. Ruthven-Murray, city electrical engineer, Worcester.

Adjournment. 1 p.m.

Reception by the Electric Lighting Committee of the Islington Vestry, Vestry Hall, Upper-street, Islington. 3.30 p.m. (The Vestry Hall is within a few minutes' walk of the Agricultural Hall and of The Angel at Islington. It is best reached from Charing Cross by cab or 'bus. Chairman of the Electric Lighting Committee, Mr. Samuel Lambert)

Discussion on paper: (8) "Combined Electric Lighting and Traction Plants," by John Hesketh (electrical engineer to the Government of Queensland, late borough electrical engineer, Blackpool) and John H. Rider (borough electrical engineer, Plymouth).

Visit of inspection to the Islington Electricity Works, Edengrove. 5 p.m. (Within a few minutes' walk of the Vestry Hall.)

FRIDAY, JUNE 12.

General meeting, for members and associates only.—Royal United Service Institution, Whitehall, S.W. 10.15 a.m. Election of president, vice-presidents, three members of committee, officers, and place of meeting for the convention of 1897. General business.

Adjournment. 12 noon.

Visit to Brighton by the 1.50 from Victoria or 2.0 from London Bridge, arriving at Brighton at 3.15 and 3 20 respectively.

Reception by the Electric Lighting Committee of the Corporation of Brighton at the Royal Pavilion. 4 p.m. Mayor of Brighton, Alderman Blaker. Chairman of the Electric Lighting Committee, Alderman Stafford.

Discussion on paper: (9) "Extensions to Outlying Districts," by A. H. Gibbings, borough electrical engineer, Bradford.

Visit of inspection to the Brighton Electricity Works, North-road, near the Pavilion. 5 p.m.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

STATISTICS.

A Fellow of the Statistical Society would probably argue that you could not possibly have a surfeit of statistics. A doubt expressed as to their universal value would be met with the statement that the statistics were all right, but that the interpretation of the statistics might be wrong. Those who are familiar with the processes of interpretation can usually approximate to a fair conclusion; but we ask in all humility, are the men who are pestered week by week with electrical statistics competent to form a correct conclusion from the mass of undigested figures put before them? Again and yet again we have been told that consultants of these figures have from them formed opinions difficult to eradicate and unutterably bad. The ever-varying conditions which determine the results are not and cannot be given, and without these a right interpretation is hopeless. Further, although such statistics may be pronounced valuable in certain instances, they are not restricted to the sight of the people who can use them profitably, but are more often used to influence the votes of men who are not familiar with all the conditions. We contend, then, that the indiscriminate use of statistics is as opposed to the true interests of the industry as is the indiscriminate use of the results of experiments with refuse destructors. Many a man has been led into error by statements that so many pounds of steam had been, and could be, obtained by the burning of refuse. In this particular direction we ought to specially caution some young and enterprising electrical engineers who are either ignorant of the ordinary conditions of refuse destruction or who wilfully suppress part of the truth, allowing their clients to make wrong inferences. Most professional men have cause to know that many of their troubles arise through indiscretions of professional brethren. Mr. Smith is unable to judge between Jones and Robinson. He has, perhaps, consulted Jones professionally, while Robinson offers gratuitous advice. Such advice is often backed up by a host of figures put forward without explanation of peculiar conditions, and, in fact, out of pure cussedness and a desire to put a spoke into a professional brother's wheel. Another system of half truths arises in the case of generation of steam by ordinary methods. Conflicting figures are shown as to cost in somewhat similar places, but nothing is said probably about local by-laws which may prohibit the use of a particular kind of coal in one place but not in the other. Suppose, for example, the restriction is to permit the use of Welsh steam coal only in one locality, while other kinds of coal are permissible in the other locality. This one condition may be the cause of the differences in the statistical figures. We have cases where the result was far different to the estimates—in fact, it usually is with those gentlemen who think more of getting in and getting their commission than of making a reputation. "You did not tell me this," says the employer; "You did not ask me," says the engineer. An answer of that kind at once stamps the man as an incompetent adviser. The employer does not engage him to suppress

Digitized by Google

material facts, but to tell the whole truth, and nothing but the truth. Sometimes complainers will ask us to name these men, and thus make a black-list. They would not mind us having the trouble and expense of litigation, though usually the request is accompanied by a postscript—"Please keep my name out of it." Others say more plainly, "We should like to see all this stopped, but we will have no hand in it; for were we to show in the matter, orders which we now get from these men would be lost to us." Candidly, is there not at the present moment far too much of this tampering with and pandering to the unstable policy of getting work at any price? There is hardly a phase of electrical engineering wherein these simple statistics have not played a wrong part. It matters little whether we deal with lighting or transmission of power or with chemical matters. The ordinary man cannot deal properly with figures, and when the ordinary man is a capitalist who is asked to embark money in an enterprise the success of which is based upon statistics, he is in a worse plight than ever. The success of electric tramways at a score of other places is no proof of their success at Little Pedlington. Similarly, the success of a particular system of electric lighting at a dozen places is no proof that that is the system for the thirteenth place. If those who use statistics would deal only with averages, there would be some reason to pay more attention to the figures; but when they deal so much with the particular, it becomes increasingly necessary to wage active war against their operations. According to the theories of certain young engineers, their work consists only in devising schemes for one or two places and duplicating one or the other of those schemes at every place they are asked to advise. The plan is very attractive, it costs little in brains or drawings, the figures are forthcoming at a moment's notice, but unfortunately the result is not always satisfactory. Said one individual: "What do I care about the future? I am full of work at the present, and making a good income, so the future must take care of itself." The careless use of statistics, with a minimum of explanatory information in lieu of real work, tends to the consideration of to-day and forgetfulness of to-morrow. The method is daily being exaggerated, and we understand that the practice of the future will be for the engineer consulted to give the consultant copies of the standard books on the subject instead of a report of some three hundred pages, backed with voluminous specifications describing one maker's specialities.

RESULTS ACCOMPLISHED IN DISTRIBUTION OF LIGHT AND POWER BY ALTERNATING CURRENTS.*

BY W. L. R. EMMET.

The introduction of successful polyphase motors has constituted a very radical and important step in the development of the electrical art. The number of persons who realise the importance of this step is as yet small, and, like other new things, it cannot attain great successes until its merits and possibilities become more or less familiar to the public and to the practical business men on whom the responsibilities for new developments must largely rest.

In the past the use of alternating currents has been almost exclusively for incandescent lighting, and this narrow limitation has crippled the development of the art. While the applications of direct currents have called forth very large investments in plants and distributing systems, the uses of the alternating currents have, as a rule, been on a much smaller scale, and the methods used have been developed rather with a view to reduction in first cost than to the attainment of the most economical results in operation.

The reasons for this somewhat half-hearted development may be stated as follows: (1) the average efficiencies attained in most alternating plants have been very low; (2) the distribution of potential obtainable with the ordinary methods has been imperfect; (3) no reliable alternating arc lamps have been available; (4) no practicable form of single-phase alternating-current motor has, up to the present time, been introduced.

At no time have all these difficulties been entirely unavoidable in alternating-current distribution; they have, however, been fixed fixtures of the system as it has in the past been installed by our manufacturing companies and used by electric light companies in this country, the state of the art being such that improvements were beyond the reach of most central-station managers. In recent years great developments have been in progress in the branches of electrical science pertaining to alternating currents. Much new apparatus has been developed, plants have been installed on new lines, and practical results are to-day being accomplished that show that it is possible to overcome all of the objections which have been mentioned. We will briefly review in order some of the means by which the difficulties mentioned have been and can be avoided.

Efficiency.—The greatest losses in the average alternating plant are due to the waste in iron cores of transformers, which goes on whether the transformers are loaded or not. This waste can be reduced either by the use of transformers of high light-load efficiency or by arrangements for cutting out transformers at light load. Where primary distribution is used with large numbers of independent transformers, the extent to which these remedies can be adopted is very limited, since reduction of core loss can be obtained only at the expense either of regulation or of first cost. If, however, secondary distribution is used—that is, low-tension mains with transformer sub-stations—it is often possible to arrange means of cutting out transformers at times of light loads. Furthermore, on such systems very accurate regulation in transformers is a matter of no importance, since all transformers divide the load more or less evenly between them instead of operating from the same line at various conditions of load as in primary distribution. Thus, for this secondary work, we can build special transformers having very small core losses and thus obtain very high all-day efficiency without impairment of regulation.

I have in mind a large plant now being equipped with alternating apparatus for lighting and power distribution on thoroughly modern and improved lines. In this case a system of three-wire low-tension mains is to be laid over a large area. These mains will be fed at street corners from specially designed transformers in ventilated manholes. These transformers are to be of 100 kilowatts each, and are to have a core loss of only 500 watts, or one-half of 1 per cent. of the capacity. The efficiency of these transformers at one-quarter load will be higher than at full load, the principal loss being in the copper. Thus a transformer may be made to fill the same functions as a direct-current feeder. If we are willing to introduce some drop between generator and main, we can get high light-load efficiency with moderate cost, and we shall retain the important advantage that transmission is possible over long distances, with small losses, through the use of high voltage.

In no branch of electrical work has the improvement of recent years been more marked than in the manufacture of transformers. This improvement has not been brought about by any radical discovery as to the principles involved,

* Paper read before the Nineteenth Convention of the National Electric Light Association, May 5, 6, and 7, 1896.

Digitized by Google

but simply by study of the economic conditions. The quality of iron is a most important matter in building transformers, and the methods of handling and annealing are almost equally so. Then the proportions by weight of iron and copper may be varied through a wide range, and the plan of arrangement of coils and iron are susceptible of endless variation. Every change of plan may affect the properties of the transformer as to self-induction, magnetising current, hysteresis, eddy currents in core and copper, resistance loss, and regulation. Thus there is much room for judgment in the design or purchase of transformers. At the price for which transformers can be bought it is folly to use bad ones. Thousands of transformers are in use to-day that are fit for nothing but the scrap pile, and many are now being manufactured and sold that are no better.

Regulation.—The cause of bad regulation in most existing alternating plants is that each individual installation is connected to a separate transformer, and that in these transformers, and the wiring connected to them, there are losses varying with the load, which, of course, cannot be controlled from the station. Since regulation is a matter of most vital importance, we see that with primary distribution good regulation in transformers is imperative. To make transformers of specially good regulation something must be sacrificed, either in economy of first cost or in light-load efficiency, or in both. Thus there is always an appreciable drop through resistance of wire in transformers, and this, combined with the drop in primary and secondary wiring, gives rise to serious vibrations in pressure on lights at different points. Another fruitful source of potential variations on alternating circuits is found in the self-induction of circuits and also in the self-induction of transformers. The E.M.F.'s introduced by self-induction being out of phase with the current, are variable in their effect, and give rise to troubles that sometimes seem erratic, although in reality they are governed by well-defined laws, which, if properly observed, enable us to obtain accurate results.

Motors.—Until very recently the operation of motors from alternating systems has been practically out of the question, since no suitable motor has been obtainable. Thus alternating apparatus has been available only for lighting, while in direct-current stations motor load during the day has been a most important source of profit. It may be mentioned here that while incandescent lighting is at the present time meeting sharp competition from other forms of illumination, the electric motor is growing very rapidly in popularity. It has taken the public a long time to gain confidence in electric power and to realise its usefulness. It is only within very recent years that large manufacturers have begun to use electrical power distribution to any great extent. At present the work is being carried on very actively, and highly successful and economical results are being obtained in many large mills. As a means of power distribution, even for short distances, electricity has no rival; while for lighting, its advantages, though great, are relatively much less positive. Although for many years efficient electric motors have been in general use, there are many central stations in whose business power distribution has not been a very important factor. There are several causes which have tended to restrict the use of electric power, among which we may mention the follpwing: Voltages that have been available for direct-current work have not admitted of transmission to considerable distances. Motors have required a certain amount of attention, which users were sometimes unwilling to bestow.

In certain classes of manufacture, the sparking of motors has been a source of danger. The most important cause, however, has been that, as a rule, the same apparatus has not been available for the operation of lights and motors; consequently, central stations have not been in a position to make attractive propositions to large users of power. The introduction of good alternating-current motors has opened a new era in electric power distribution, and seems to promise a great extension of its uses. With these motors the difficulties of distance are practically eliminated, since there is virtually no limit to the voltage which can be used. The mechanical features of the motor are near perfection, since it requires no care save what must be bestowed on its self-oiling bearings. These motors can be so arranged that they may be operated with perfect safety in any part of a powder-mill or oil refinery, and, in fact, a number of them are being operated now in highly explosive atmospheres, where a spark would work destruction.

With facilities for electric power transmission thus improved, we may look for great developments in the sale of power from central stations. When it is profitable for large manufacturing establishments to put in electric plants for the purpose of distributing power on their own premises, there should certainly be profit in the sale by electric companies of power to large as well as small manufacturers. The actual saving in fuel effected in the operation of a large mill by electricity for power distribution is ordinarily very large, often as much as 50 per cent. With good equipment this is, however, only a small part of the saving effected by electrical distribution. The cost of coal seldom amounts to more than half the expense incident to the production of power, and in most cases it is a much smaller proportion of the total. If power is obtained from a central station the coal is bought cheaper and used more economically, while the other items of expense will in many cases be almost a clear saving. The introduction on any large scale of electrical power distribution, of course, requires the investment of a good deal of money in motors and alterations of plant. Power users are often slow to make these investments because they are not familiar with electrical apparatus and do not realise the advantages to be gained. Repeated investigations have proved that users almost always far underestimate the cost of power. It is the business of the central-station manager to correct these misconceptions, and to awaken interest in electrical methods. Of course, many companies are working zealously just on these lines. There is no question, however, that there is in many of our large cities a large amount of undeveloped power business. If electrical manufacturers can induce large millowners to put in plants for electrical power distribution, central stations should be able to sell power to similar concerns.

The following facts concerning sale of alternating power apparatus by one company alone will illustrate the hold which the modern improvements above mentioned have already taken upon the industry of the country. The first three-phase apparatus made in this country was put in operation 2½ years ago. Since then that company has put in operation 33,500 h.p. capacity in three-phase generators, 10,000 h.p. in three-phase induction motors, 14,800 h.p. in monocyclic generators, 6,000 h.p. in three-phase synchronous motors, 10,560 h.p. in rotary converters, and 42,000 h.p. in transformers used for power purposes; the average capacity of the latter being 16 h.p., and the largest having a capacity of 1,100 h.p. The production of this apparatus has involved the complete design and development of about 30 new forms of dynamos and 33 new forms of motors; each machine so developed involving the construction of new patterns and special tools, which, with drawings, etc., cost in the average about 1,000dol. for each new machine. The development of so large a number of different machines has been made expedient by the engineering conditions that have been met. The matters of speed, frequency, voltage, and capacity must all be considered in deciding upon the best apparatus for any given purpose; and, of course, it is, generally speaking, unwise to use anything unsuitable, even though it be of standard production, and for that reason desirable. The expense involved in the production of all these machines is great, but it is in the long run money well invested, since it puts the manufacturers in a position where they can bid to advantage on the apparatus best suited to any case. It also brings a fund of experience that may be of more value than the tools, patterns, and drawings. The uses to which all this apparatus has been put are various. All sorts of new problems have presented themselves, and have been solved in widely different ways suited to the conditions. In many cases the apparatus built has been of types radically different from anything previously produced. In the past the principal production of American electrical manufacturers has been from standard lines of apparatus, and we still endeavour to

Digitized by Google

keep up this most economical and excellent practice. Since, however, we are now constantly called upon to produce special apparatus, we try to so standardise and systematise our methods that new work can be turned out promptly and economically and without risk of failure. The different methods of distributing power and light by alternating currents can best be illustrated by diagrams showing the connections used with each. We will briefly review some of the applications of the systems now in general use.

Fig. 1 shows the three-phase system as ordinarily applied to the transmission of power for lighting and other purposes over long distances. The generator may be of any convenient voltage, since step-up transformers are used. These

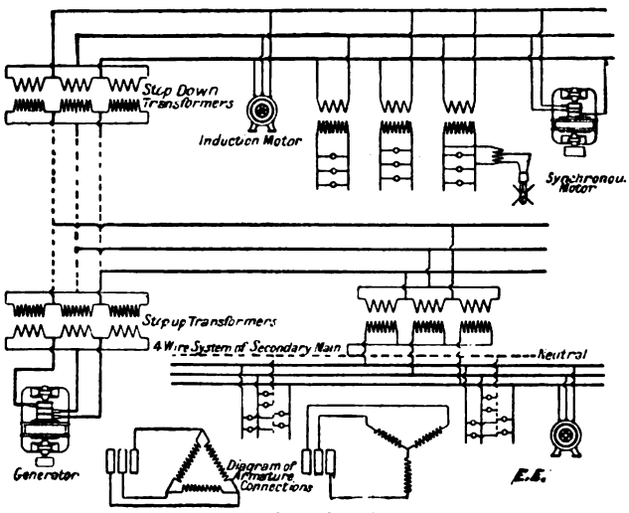

FIG. 1.—Three-Phase System.

transformers are in three units, or groups, any two of these units being available to transmit a large proportion of the power in case one is disabled. Two sets of step-down transformers are shown, one supplying 1,000-volt distributing lines, and the other supplying a system of four-wire secondary mains. With a given lamp voltage such mains give a slightly better copper economy than the ordinary three-wire system, and afford an excellent means of secondary distribution. Such a system as is illustrated in this figure will give excellent service in almost any town, the low-tension mains taking care of the thickly built-up portion and carrying the bulk of the lighting load, while the high-tension distributing system covers all outlying portions and operates large power units. A number of large plants have been installed within the last two years, using the three-phase system, as here shown.

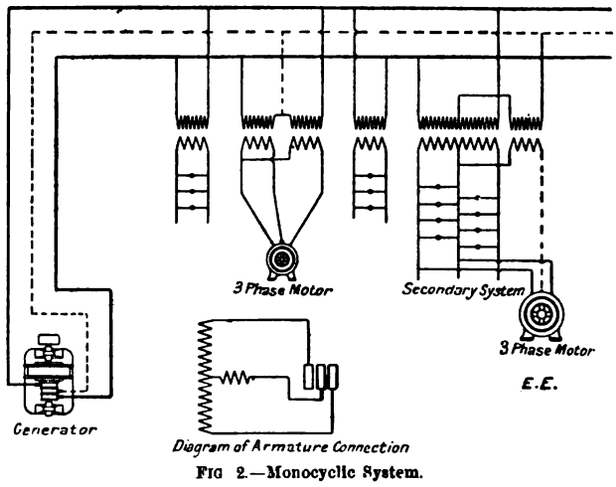

FIG 2.—Monocyclic System.

Fig. 2 shows the connections for distribution by the monocyclic system. Here all lights are connected single-phase between a single pair of conductors leading from the generator, the motors being operated from the same single-phase circuit in combination with a third conductor leading from what is known as the "teazer coil" on the generator. Here the simple three-wire system is used for secondary distribution, and if it is desired to connect motors to the low-tension mains, a supplementary transformer is used, which supplies a secondary teazer wire; to this and the outside wires of the three-wire system the motors are connected.

The great merits of the monocyclic system are that the number of conductors required for lighting and power distribution is reduced to a minimum, and that no unbalancing is possible. The operation of three-phase motors from this system is in all practical respects the same as when they are run from three-phase circuits.

Fig. 3 shows the connections of the two-phase system, with distribution by four conductors. Here the lighting is divided between two separate circuits, which must be kept balanced within certain limits, depending upon the regulation of the generator or the amount of care that can be given to the adjustment of pressure on the different

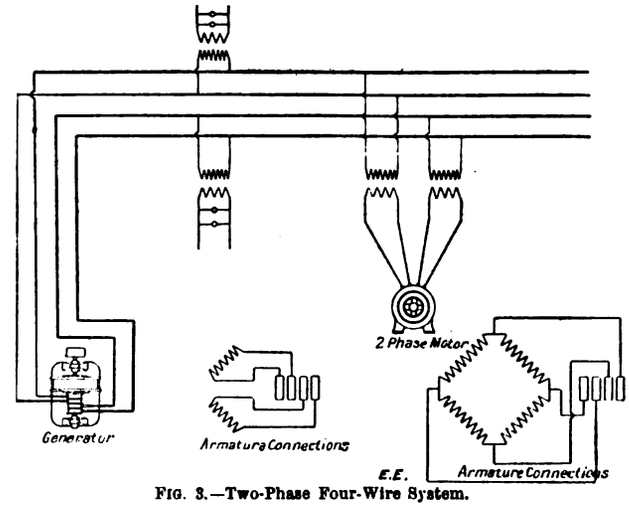

FIG. 3.—Two-Phase Four-Wire System.

sides. Where motors are run, the two circuits must be brought together. There is no economical and convenient way of operating secondary distribution from this system. Two independent three-wire systems could be operated, but these must be brought together when motors are to run. The complication of balancing such a system would be prohibitory. The two-phase four-wire system can be operated either from a generator with two independent circuits, or all four conductors can lead from one armature winding. Certain advantages may be claimed for both methods, and both have disadvantages.

Fig. 4 shows a method of single-phase lighting distribution from a two-phase dynamo. Here the two single-phase leads are taken out at points 180deg. apart on a progressive armature winding. At points 90deg. from those leads two other leads are brought out; each of the latter can be used with the pair of single-phase leads to run one-half the

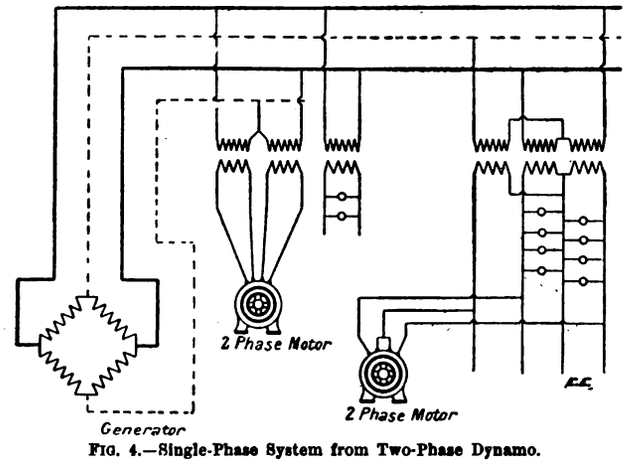

FIG. 4.—Single-Phase System from Two-Phase Dynamo.

capacity of the machine in two-phase motors. These two power leads cannot, however, be brought together. The greatest disadvantage of this system is that, when carrying a single-phase load, a large proportion of the armature conductors are ineffective, and simply introduce useless resistance and self-induction in the circuit. Thus with the same loss the generator will deliver 42 per cent. more power as a quarter-phase machine than it will as a single-phase machine.

Digitized by Google

Fig. 5 illustrates the two-phase three-wire system, which has been used to some extent both for high-tension distribution and for distribution by secondary mains. The principal advantage in this system is that it requires one less conductor than the four-wire two-phase system. Its disadvantages are that the insulation of the apparatus is subjected to a voltage 42 per cent. higher than that which is available in transmission, and that the self-induction in the lines and transformers causes an unbalancing of the voltages on the two sides of the system, accompanied by

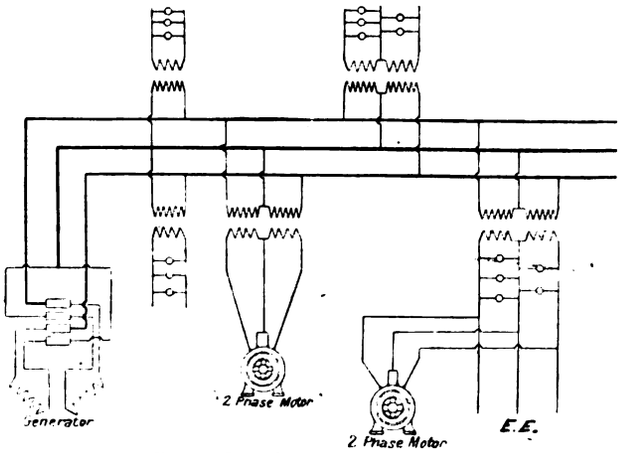

FIG. 5.—Two-Phase Three-Wire System.

the distortion of the phase variation. The extent of this unbalancing depends upon existing conditions, and is very different in different cases.

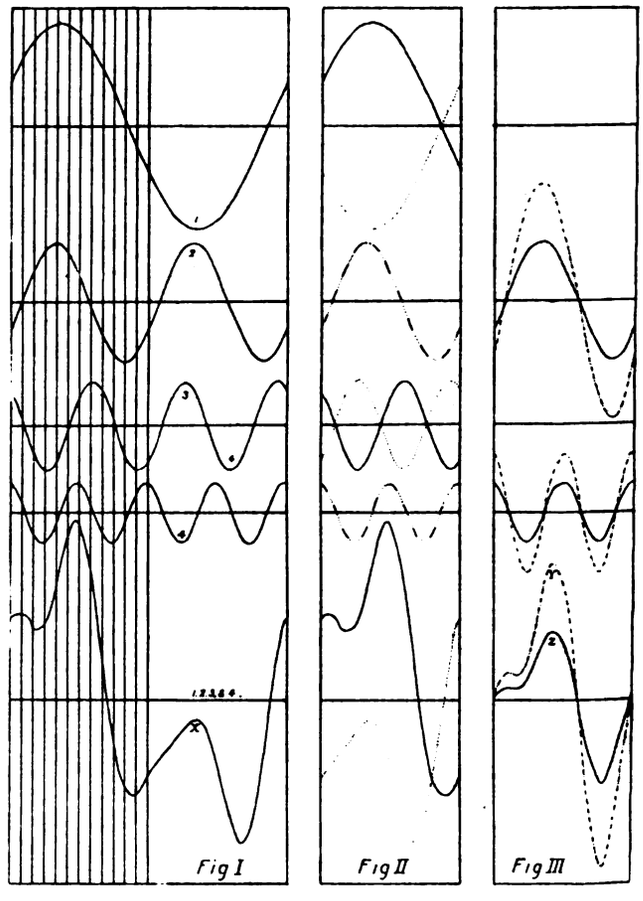
(To be continued.)

A SIMPLE METHOD OF ANALYSING PERIODIC CURVES.*

BY E. BASIL WEDMORE, STUDENT.

No excuse is needed for bringing this subject before you this evening. The mathematical electrical engineer in all problems dealing with alternating or other periodic currents has to deal with forces and quantities that vary as some harmonic function of the time. We know that it is a common practice to assume that these variations follow a simple sine law. Where this is not admissible many problems are quite insoluble, unless we use some method of analysing the law of variation into a series of simple sine functions, which can then be dealt with separately by the usual methods. We believe that there are many who avoid such calculations solely owing to their not being acquainted with any simple method of analysing harmonic curves, or owing to their not having the necessary instruments or apparatus for using one of the methods more generally known. The curves of voltage, current, and magnetisation are to electrical machinery what the indicator diagram is to the steam-engine; and we venture to believe that the solving of many problems depending on the peculiar form of these curves, such as the best form of curve for incandescent lighting, or transforming under various conditions, might be considerably simplified by studying the analysis of the curves. The analysis might form a half-way station at which the manufacturing and lighting engineers might meet—the one studying the qualitative effects of the various components on the apparatus that he uses, and the other studying the methods of producing the various components required.

But to return to the subject of this paper. I propose, firstly, to enunciate the principle; secondly, to give examples of its application; and then to prove the method analytically and geometrically. Special attention will be given to those cases more immediately applicable to electrical problems and to the effect of errors in the curve analysed. A few special cases will also be pointed out where rather interesting points arise. It may be as well to point out at this juncture, in case any present are not acquainted with the fact, that Fourier has shown that any periodic function is the resultant of a number of simple harmonic functions, which, as we know, may be represented by sine curves. The object of the analysis is to find these component curves, their phase and amplitude. It has been pointed out that the method about to be described is analogous in some respects to the use of chemical reagents in chemical analysis. Each application of the process separates out from the given curve those component sine curves whose periodicity is some simple multiple of the divisor or reagent used. Each of the prime numbers may be used as a reagent, and will separate out all those curves whose periodicity is some simple multiple of the number used. For the appplication of this method it is necessary to obtain one complete period of the curve to be analysed. (It is hardly necessary to point out that one complete period must contain a whole number of periods of each component). The method consists of a continual application of the following process: "Draw the curve so that the independent variable, say time, is horizontal. Divide the curve vertically into any number of equal parts, say N parts. Superpose the parts, and algebraically add them." The result will be another curve consisting only of those components whose periodicity, as compared with that of the original curve, is some simple multiple of N, all other components having been eliminated. Thus in Fig. 1 we have one period of a curve, X, composed of four components shown above it and numbered 1, 2, 3, and 4. The figure is divided into two parts (*i.e.*, N=2), and in Fig. 2 the parts are superposed, their algebraical sum being shown in Fig. 3. Here it will be seen that curves 1 and 3, having one and three periods respectively, have been reduced to zero, 1 and 3 not being equal to N or a multiple of N; while 2 and 4, whose periodicities are respectively equal to N and a multiple of N, have been reproduced; with their amplitudes, however, doubled, or multiplied by N. The component curves, Nos. 1,



2, 3, and 4, are given only to show the effect of the process when applied to curve X, and have nothing to do with that application. We see that by operating on X with the number "2," we have obtained a curve, Y, consisting only of those curves whose periodicity is some multiple of 2, with their amplitudes doubled. If, now, we reduce the amplitude of Y by one-half, we shall obtain a curve, Z, which contains only half the components. For the complete analysis of the curve it would be necessary to proceed as follows, being careful always to reduce the amplitude of each curve obtained to its original value—*i.e.*, divide it by N—before operating with it: (1) Divide Z into two parts and proceed as before, thus obtaining component 4 (having a periodicity = twice that of curve operated upon); (2) subtract 4 from Z, and thus obtain 2. (Z − 4 = 2 + 4 − 4 = 2); (3) subtract Z (that is, 2 and 4) from X, and you will obtain 1 and 3 combined $\{(1+2+3+4)-(2+4)=(1+3)\}$; (4) divide this curve (1 and 3) into three parts and proceed as at first, and you will obtain No. 3; (5) subtract No. 3 from 1 and 3, and you will obtain No. 1.

We have now obtained all the components, and each in its respective position with regard to the original curve. Fig. 4 contains the complete analysis. The figure is complicated somewhat by the necessity of reducing the amplitude of curves when obtained by addition of ordinates, and the number of curves to be drawn has been increased by the necessity of spreading the analysis over three lines for the sake of clearness.

* Paper read at a students' meeting of the Institution of the Electrical Engineers.

If the work is done on a larger scale, this is quite unnecessary. The curves drawn in full, with the exception of the first one, are the result of a complete operation, the other curves being intermediate steps. The dotted ones are curves redrawn merely for convenience in superposition. (This is quite unnecessary after one has obtained a little experience.) The dot-and-dash curves are curves as first obtained, which require to have their amplitudes corrected. The curves are numbered in the order in which they are obtained. Curve 2 is X superposed. Curve 3 is the same as Y, and curve 4 is Z, and contains all the even-numbered components. Curve 4 is bisected, and the two halves being superposed we obtain curve 6, which, reduced by half, gives us 7, one of the components (No. 4, Fig. 1). Subtracting curve 7 from 9 (which is 4 reproduced) we obtain 10, the second component. We now return to the original curve and operate with "3." The parts are superposed on the right-hand side of the figure. Curve 13 is the algebraical sum, and 14 is 13/3, and is the third component. Subtracting 16 (which is = 4) from 1 we obtain 17, which consists of components 1, 3, 5, etc. (the odd numbers). Subtracting 14 from 17 we obtain 18, which is the first component. We see that curves 18, 10, 14, and 7 are respectively similar in all particulars to Nos. 1, 2, 3, and 4, in Fig. 1. Twenty-four ordinates were used in this analysis, but the lines have been left out for clearness. The first 12 are shown in Fig. 1. Of course squared paper might have been used. By the use of a proportional compass, set to make the amplitude corrections, we might have left out all the curves except the six shown in full line, four of which are components; and in Fig. 10, which is the analysis of a transformer curve, to be again alluded to, we might have drawn the components straight away.

A very simple calculation explains the curious properties of periodic functions which enable us to obtain our results in this simple manner. Let N = number of parts, and P = number of periods of any component. We may write the P^{th} term of Fourier's series thus:

$$P^{th}\text{ term} = A_\rho \sin P \frac{2\pi}{T}(t+\phi_\rho).$$

After dividing the curve into N parts, the parts may be represented by the following:

$$1st = A_\rho \sin P \frac{2\pi}{T}(t+\phi_\rho);$$

$$2nd = A_\rho \sin P \frac{2\pi}{T}\left(t+\frac{T}{N}+\phi_\rho\right);$$

$$3rd = A_\rho \sin P \frac{2\pi}{T}\left(t+\frac{2T}{N}+\phi_\rho\right);$$

$$last = A_\rho \sin P \frac{2\pi}{T}\left(t+\frac{(N-1)T}{N}+\phi_\rho\right).$$

We note that each term differs (in phase) from the preceding one by an equal amount:

$$P\frac{2\pi}{T}\times\frac{T}{N} = 2\pi\frac{P}{N}.$$

The sum of these expressions, which, of course, represents the resultant of the superposition, is as follows:

$$\Sigma_\rho = A_\rho \frac{\sin P\pi}{\sin\frac{P}{N}\pi} \sin P\frac{2\pi}{T}\left(t+\frac{N-1}{N}\cdot\frac{T}{2}\cdot+\phi_\rho\right).$$

The coefficient of frequency with respect to that of the original curve—namely, P– being always a whole number, the factor:

$$\frac{\sin P\pi}{\sin\frac{P}{N}\pi}$$

will be zero, except where $\frac{P}{N}$ is also a whole number—*i.e.*, except when P = N or a multiple of N—in which case the factor takes the form $\frac{0}{0}$, the resolution of which leads to the value ± N.

If it is – N, then the right-hand part of the expression will also be negative, therefore their product or the whole expression will still be positive.

We may see also that in the case where $\frac{P}{N}$ is a whole number, the factor $P\frac{2\pi}{T}\cdot\frac{N-1}{N}\cdot\frac{T}{2}$, in the right-hand side, which, simplified, becomes $\frac{P}{N}\cdot(N-1)\pi$, will be a simple multiple of π, having no effect on the expression, as $\sin k\pi$ = zero, if k is a whole number; we may therefore eliminate it. Finally, then, we see that when P is not a simple multiple of N, the sum is zero, but when P is a simple multiple of N, making $\frac{P}{N}$ a whole number, the expression for the sum becomes

$$N A_\rho \sin P\frac{2\pi}{T}(t+\phi_\rho),$$

which is exactly the same as the original curve, except that its amplitude is multiplied by N, the number of parts. We note that the phase has not been altered.

For the benefit of those who may have found some difficulty in following the analytical proof, we propose now to give a proof by means of the clock diagram. We see that in performing the superposition we are really superposing a number of curves differing only in phase. We might take any number of periods of the original curve and superpose the whole upon itself either graphically, analytically, or by the clock diagram, N times, differing by $\frac{1}{N}$th of a period in phase. The result would be just the same. Thus in the analytical proof just given we see that the expressions representing the several parts are really expressions representing not only a short length of curve, but any number of periods of a periodic curve, and the proof given holds good whether we only take parts of a period, as in the figure, or whether we take any number of periods. Now, we know that we may represent any given combination of sine functions by vectors in a clock diagram, the lengths of the vectors representing amplitudes, and the angles between the vectors and some fixed line passing through the same centre representing the lags and leads. We know also that, if these vectors are projected on to a line at right angles to this fixed line, the lengths of the projected portions will give us at any moment the instantaneous values of the quantities represented by the vectors. One period of either component will be represented by one revolution of the corresponding vector, therefore one complete period of the combination will be represented by one revolution of the first component, two of the second, three of the third, etc. Fig. 5 shows a vector, O A, and "a" is its instantaneous value. O Y is our fixed line. If the figure was drawn at time 0, then $\sin^{-1} a$ = angle of lead. Fig. 6 contains a vector, one revolution of which gives us one period. The period has been divided into three equal parts, and the curves to be superposed are represented by the vectors I, I_a, and I_b, which we see differ in phase by one-third of a period. Now, according to our rule, as 1 is no multiple of 3, the quantity should cancel, and we see that it does so, whether we resolve the diagram by the parallelogram of forces or by projecting on to a fixed line. The projections are shown, and marked a, b, and c, and it is evident that $b + a - c$ = zero. If we had taken three periods—that is, three revolutions—and divided into three parts, the parts would have been coincident, and our vector would have been trebled, and our rule says that, as 3 is a multiple of 3 (P = 1 × N × 1), the resultant will be a curve of the same periodicity and phase, but of three times the amplitude of the original curve. Fig. 7 represents the curve X in Fig. 1 at time 0, also the result of the first operation, and we see that, while 1 and 3 are cancelled, 2 and 4 are doubled. Fig. 8 represents a combination divided into three parts, with the expected result. The clock diagram cannot, of course, be used for analysing the curve, as we cannot draw the vectors until we know the components. A certain artifice may be used, however, in certain cases, which will enable us to construct the clock diagram directly from the curve. (See Appendix.)

The curves obtained from alternators and transformers present a peculiar form of symmetry. The positive and negative portions of the curve are exactly similar in shape. This must be so from the symmetry of the apparatus producing the curve. If the north poles of an alternator were shaped differently from the south poles, we should then have an unsymmetrical curve. Perhaps some enterprising individual may yet show that this is the best arrangement. There is, at any rate, a very great difference between the components of a symmetrical and an unsymmetrical curve, in so far as that the one consists solely of components whose periodicity is an odd number as compared with the original curve, while the components of the other must be even, or odd and even. This will be comprehended at once on inspecting Fig. 10, where we see that if the curve (No. 1) were bisected and superposed the result would be zero, showing that there cannot be any components with periodicity = 2 or a multiple of 2. If, as in Fig. 11, No. 2, we obtain looking-glass symmetry *i.e.*, the positive or negative parts symmetrical in themselves—then there can be no difference of phase between the component curves. Where, as in Fig. 11, there are only two components, the vertical height, measured one-quarter period from zero, equals the sum or difference of the components, and the mean ordinate multiplied by $\frac{\pi}{2}$ equals the principal ordinate ± $\frac{1}{P}$ times the Pth ordinate; from which equations we may obtain both components.

With regard to the effect of errors in working the method, or of errors in the original curve, there are several points to be noted. Firstly, if we could remove the components from the curve and leave behind only the errors, these would form a

Digitized by Google

curve of irregular form, which might nevertheless be analysed into a number of component sine curves of various periodicities. As the curve would be very irregular, a great many components would be required to accurately represent it. However, the point is that in this error curve there is a component of periodicity = 1 (its value might, of course, be zero), there is a component of periodicity = 2, of periodicity = 3, etc. The amplitudes of these components may be small in comparison with that of the error curve, and ∴ very small with respect to those of the original curve. Now, when we analyse the original curve, it is evident that the component of the error curve of periodicity = 2 will be removed with the component of the original curve of periodicity = 2, and so with any other component: each component we separate from the original curve will be erroneous to the extent of the component of the same periodicity of the error curve. But what of the other components? Let us consider the first 24 only, and assume that we have analysed the curve to the sixth, then we have 18 to consider. Now nine of these will disappear, as we can easily show. Fig. 12 contains two curves, No. 2 having twice the periodicity of No. 1. If 1 and 2 were added, we should add to the positive part of No. 1 just as much as we subtracted from it, and the same with the negative part; in other words, the area would remain unaltered. If, therefore, we take any curve

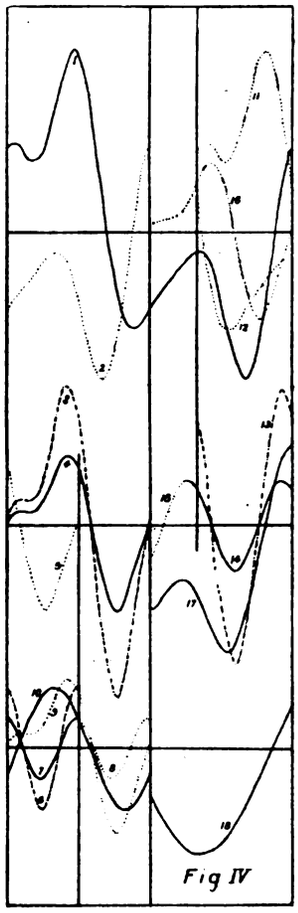

Fig IV

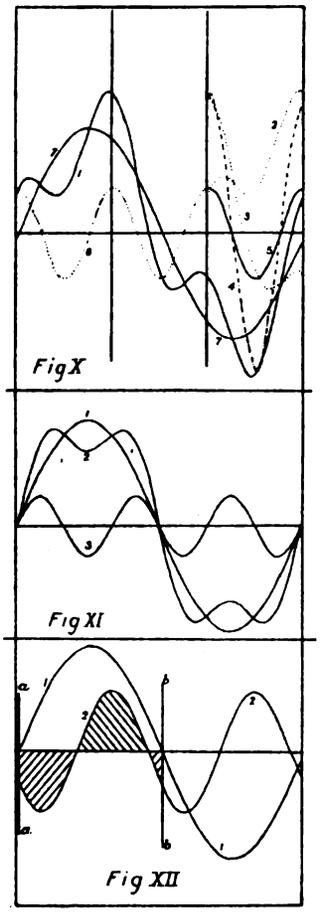

Fig X

Fig XI

Fig XII

containing errors whose periodicity is an even multiple of that of the curve, these errors will be eliminated by drawing a smooth line through the inequalities—*i.e.*, keeping the area the same—or by finding the amplitude by taking $\frac{\pi}{2}$ times the mean ordinate. Therefore all even-numbered ordinates in the error curve disappear. With regard to the others, let us consider the seventh. As it is a prime number, it would appear in the first component. If its zero coincides with that of that component, then the effect will be that the area of each half of the curve will be increased or diminished by an amount equal to that of one-half period of the error component. If the maximum of the error curve coincides with the zero of the other, then the areas will not be altered, and the error will cancel. The probable error per ordinate will be about two-thirds of one-seventh of the mean ordinate of the error component.

The same reasoning applies to the other components, the particular curve they appear in depending on what number their periodicity is a multiple of. We find, therefore, that the error in any one ordinate of any component will probably be much less than the mean error in the ordinates of the original curve. In fact, if we analyse an erroneous curve, and then reconstruct it from its components, its last state is much better than its first. If, on the whole, the positive errors are greater than the negative, or *vice versâ*, then the difference will be removed with the constant term.

It is essential in this method, as in others, that the constant term, if there be one, be eliminated at the outset. There rarely is one, however. To give a practical illustration; I have the analysis of a curve that might have been taken from a transformer. The mean error in the ordinates is 2 per cent. There are two components. The mean error in the smaller one is ½ per cent., in the larger one ¼ per cent.; and, as these components are themselves smaller than the original curve, it is evident that most of the errors have been removed. It is possible, by performing the analysis arithmetically instead of graphically (by writing down the ordinates in figures and performing the operation on them arithmetically), to reduce the error to smaller proportions, even if only working to two significant figures. We might point out that, if there is a large error in one or more ordinates, it will be spotted at once while working.

With regard to the arithmetical method of performing the analysis—which is the most accurate where it can be applied—the procedure is the same as that used in the graphical application. We give below the complete analysis of the curve X (Fig. 1) to correspond with Fig. 4; also the analysis of curve No. 1 (Fig. 10) showing the method of finding phase and amplitude. You will see that it only takes seven columns of figures to separate four components, and as three columns are

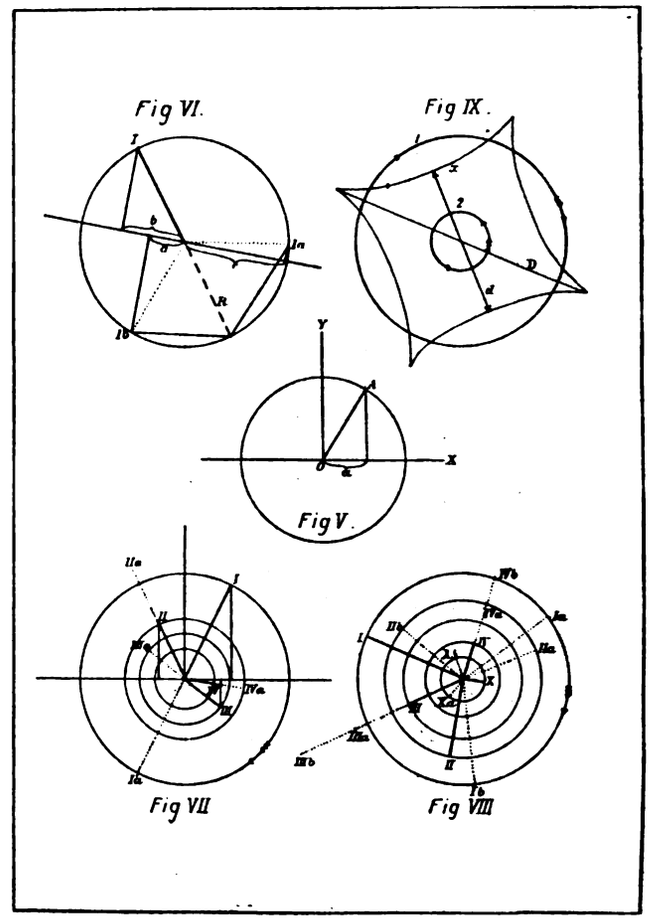

Fig VI.

Fig IX.

Fig V.

Fig VII

Fig VIII

taken up by the question and answer, one can hardly consider the method a slow or tedious one. If the curves are plotted to a large scale on squared paper, and a proportional compass is used, the work may be done very rapidly. It has already been pointed out that in Fig. 10 the answer might have been written down straight away, and when we consider that 15, or even 9, ordinates would have given us fairly accurate results, we see that the work of analysis by this method is reduced to a minimum. The number of ordinates taken must be a multiple of the periodicities of all the components we wish to separate, and we must have at least three points per period of any curve we wish to find, as two points leave both amplitude and phase indeterminate. This, however, is not very serious. In electrical problems 15 ordinates will suffice to find the first, third, and fifth components, and if we wish to find the seventh we must redivide our curve. When a small number of ordinates are taken, it is best that their number shall be an odd multiple of the periodicities of the components to be separated.

It will be seen that as columns B, E, I, J, and M, and parts of G and L, are only written so that figures may be added or subtracted conveniently; they are unnecessary. The fingers of the left hand may be used to mark the figures to be operated on. Thus, by putting the thumb and first finger on lines 0 and 12, in column A, and slipping them down one line at a time while adding, we can write column C without first writing column B, which is merely A repeated from line 12 downwards,

39°/3 = 13°

Complete analysis of transformer curve (see Fig. 10).

In the above, the correct values for the amplitudes are 3 and 7, so small errors have crept in owing to our using only two figures and nine ordinates. The phase, however, is correct. $\sin^{-1} 0{\cdot}633$ gives us 39°; but, as this component has three periods to one of the original curve, we must reduce this lead by one-third to make it comparable with the other.

APPENDIX.

Where there are only two components we may construct the clock diagram direct from the curve by a simple artifice. This method, however, is not so quick or accurate as those just described, and is given here only because of its theoretical interest.

If we combine two simple harmonic motions, of the same amplitude but differing in phase by one-quarter period, at right angles to each other, we shall obtain circular motion. Thus, if we combine, at right angles, the vertical ordinates of two similar sine curves, differing in phase by one-quarter period, we shall obtain a circle. If, therefore, we take the vertical ordinates of two periods of the given curve differing in phase by one-quarter period, and combine them at right angles, the resultant will be a combination of circular motions.

Fig. 9 gives a curve obtained in this manner from a curve of two components of periodicities 1 and 3. The minimum diameter of the figure, d, obviously corresponds to the position where the circular motions are opposed to each other, while the maximum, D, is produced when the motions assist each other. $\frac{D-d}{4}$ gives us the amplitude of the smaller component, and $\frac{D+d}{4}$ gives us the amplitude of the larger component. From the position of either diameter with respect to the original ordinates we may easily obtain the phases, remembering that the circles are travelling in opposite directions, because when we shifted the original curve through one-quarter period we shifted the smaller component through three-quarter periods. If the second component had had five periods, we should have shifted it through ¼ periods, which has the same effect as one-quarter, and the circles would revolve in the same direction. If the smaller component had had an even number of periods, we should have shifted it through a certain number of half periods, the result of which would have been to have given us a diagonal line, which would have made the resultant figure elliptical.

We might analyse any curve by this process by the help of a few more artifices which enable us to eliminate groups of components, but the process is very tedious.

STAFFORD CORPORATION.

The electric lighting department accounts for the year ended on March 31, 1896 (five months' working only), have just been issued. The expenditure authorised was £15,000, but the actual expenditure has already exceeded that amount by £969. 1s. 8d. We give herewith an abstract of the revenue account, net revenue account, balance-sheet, and statement of electricity generated, sold, etc.

TUNBRIDGE WELLS.

We give below an abstract of the accounts for the Tunbridge Wells electricity works for the period ending March 31, 1896 (about seven months). The amount authorised to be spent for the purposes of the undertaking is £25,000, of which £15,408. 18s. 9d. has been expended. It will be seen from the net revenue account that a profit of £737. 13s. 7d. has been made on the seven months' working:

Dr. REVENUE ACCOUNT.	£	s.	d.
Coal, or other fuel, including dues, carriage, unloading, storing, and all expenses of placing the same on the works	299	7	11
Oil, waste, water, and engine-room stores	24	15	11

COMPANIES' MEETINGS AND REPORTS.

WEST COAST OF AMERICA TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held last Friday at Winchester House, E.C., Mr. J. Denison Pender presiding.

The **Chairman**, in moving the adoption of the report, a summary of which has already appeared in our columns, said the gross income for the year had been £32,930, being an increase of £11,176 over that of the previous year, but this included a rebate

Digitized by Google

of £3,140 made to the Company out of the international traffic receipts by two of the associated companies. During the early part of last year the local traffic receipts were sufficiently favourable to justify the hope that the year's working would result in their making both ends meet, but later on the local traffic fell off, mainly in consequence of the stagnation in the nitrate trade, and this falling off lasted during the remainder of the year. Only the rebate had enabled them to meet their working expenses and pay their debenture interest. The expenses for the year had been £776 in excess of those for 1894, principally owing to the higher sterling value of the Chilian dollar. The completion of the arrangements among nitrate producers to restrict the output for a term of years and the disappearance of the friction hitherto existing between Chile and Argentina would, he thought, produce a revival of trade on the West Coast, and have a beneficial effect on their local and international traffic. The latter class of traffic had grown steadily since the opening of the line between Valparaiso and Buenos Ayres in March, 1894. After referring to the excellent working of their system, the Chairman wished to make it clear that the special rebate which relieved them of what would have been a loss of £3,140 on last year's working must not be taken to mean that in the event of a deficit this year it would be wiped off in a similar way. Their normal proportion of the international traffic receipts was fixed at the commencement by the associated companies, and it was fully anticipated that this Company's share of the pool, added to their local traffic receipts, would be sufficient at least to pay their working expenses and the debenture coupons, if not to leave a balance over. Last year's working, owing to temporary causes, did not realise these anticipations, and having regard to the general policy which resulted in the formation of the Pacific and European Telegraph Company, and the alliances thereunder, the special rebate was allowed to this Company, it being, however, clearly understood that a precedent had not been thereby established. They were, however, really getting within measurable distance of making both ends meet.

The resolution was seconded by **Mr. F. Walters** and carried unanimously.

WEST AFRICAN TELEGRAPH COMPANY.

The report of the directors of the West African Telegraph Company, Limited, for the year ended December 31 last, to be presented to the general meeting to be held in London on 11th inst., states that the Company's revenue for the year amounted to £74,333, against which £17,474 is charged for ordinary expenses and £6,298 for expenditure relating to repairs of cables, etc. After providing £876 for income tax, and £25 due to revaluation of currency assets, there remains a balance of £49,660. From this amount there has been deducted £11,323 for interest on debentures and £12,333 for sinking fund, leaving a balance of £26,004, out of which the directors have placed £15,000 to the general reserve fund. For the six months ended June 30, 1895, an interim payment of 2s. per share has been paid, and the directors now recommend a final dividend of 6s. per share, making 4 per cent., free of income tax, for the year. The balance of £1,760 it is proposed to carry forward.

ELECTRIC TRACTION COMPANY, LIMITED.

The report of the directors for the year ended December 31 last states that the allotment of the Company's share capital took place on June 18, 1895 The whole of the share capital has been subscribed. The deferred shares are fully paid, and £2 per share has been paid on the ordinary shares. On June 18, 1895, the Company entered into a contract with the Central London Railway Company for the acquisition of the necessary land and the construction and equipment of the railway, with all its appurtenances, to the satisfaction of the railway company's engineers. Immediately after the execution of the above contract, this company proceeded with the compulsory acquisition of the properties required for the station sites and the generating depôt at Shepherd's Bush, with the result that, thus far, upwards of three-fourths of the total number of claims have been settled or adjudicated upon. This work is being pushed forward as quickly as possible, so that possession of station sites may be obtained to enable the work of construction to be commenced not later than July 1 next. The line from Shepherd's Bush to the Bank has been divided into six sections, and on February 19 last a selected number of firms were invited to tender for the construction of the tunnels and shafts and incidental work. A considerable number of tenders having been received the directors have entered into the following sub-contracts: sections 1, 2, and 3, Shepherd's Bush to Marble Arch, Mr. J. Price; sections 4 and 5, Marble Arch to Post Office, Messrs. Walter Scott and Co.; section 6, Post Office to Bank, Mr. G. Talbot. The arrangements with regard to the station at Liverpool-street are progressing satisfactorily. The prices at which these sub-contracts—which cover the principal part of the work of construction—have been let, and the cost of acquiring the station sites are fairly in accord with the estimate formed as to the cost of the undertaking, and confirm the directors' anticipation that the construction and equipment of the Central London Railway will be carried out within the contract price, with a fair margin of profit to this Company.

Direct Spanish Telegraph Company.—For the month of May the receipts were £2,396.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ecija (Spain).—The Municipal Authorities of Ecija want tenders by July 2 for a system of electric lighting for the town.

Cherbourg.—The French Ministry of Marine are asking for tenders, by June 18, for the supply of a quantity of electric fittings.

San Sebastian (Spain).—The San Sebastian Tramway Company ask for tenders, by July 1, for the application of electric traction to their line.

Benevento (Italy).—A concession for installing and working the electric lighting of the town of Benevento is open to be tendered for up to June 20.

Mako (Hungary).—The municipal authorities of Makö in Hungary are desirous of receiving proposals for the electric lighting of the town.

Utrera (Spain)—Tenders are wanted by the Municipal Authority of Utrera for the installation of electric lighting. The last date for receipt of tenders is July 1.

London, S.E.—Tenders are required for complete installation of electric lighting. For particulars apply by letter to Mr. H. Freeman, 44, Knatchbull-road, Camberwell, S.E.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31.

Gardia (Spain).—The Municipal Authorities of Gardia, in the province of Toledo, will proceed to adjudge the contract for the electric lighting of the town for 20 years on June 10. The annual payment suggested is 14,000 pesetas (about £560).

Ocana (Spain).—The Ocana Municipal Authorities are open to receive tenders, up to June 30, for the electric lighting and water supply of the town. The annual payment suggested is 10,000 pesetas (about £400). Ocana is in the province of Toledo.

Brussels.—Tenders will be received shortly (the exact date is not yet announced) at the Brussels Bourse for the material and work necessary to start an electric lighting installation at the fifth section of the central locomotive construction works at Malines.

Alberique (Spain).—The Municipality of Alberique, in the province of Valencia, want offers for the electric lighting of the town for a period of 10 years. The annual payment suggested is 3,250 pesetas (about £140), and tenders must be sent in by June 12.

Brussels.—On June 17 there will be a reallotment of contracts for the conversion to a system of electric traction of about 12½ miles of local light railway. Application for particulars (price 1fr.) should be made to la Société nationale des chemins de fer vicinaux, rue de la Science 28, Brussels.

Spandau.—Tenders are wanted at the Royal Small-Arms Factory for 900 incandescent electric lamps by July 17 and for 27,300 sets of arc-lamp carbons by June 12. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21), Spandau.

Alford (Lincs.).—The committee appointed for lighting the town are prepared, on and after June 5, to enter into a contract for lighting the town with gas or other light from August 14, 1896, to May 14, 1897. Tenders will be received up to June 6 at the office of the committee, West-street, where all particulars may be obtained. Mr. E. W. Rushton, clerk.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Dresden.—The Telegraph Department of the Saxon State Railways want tenders by June 10 for about 50 tons of galvanised iron wire (4 millimetres) and 10 tons of smaller sizes; also 3,700 glass jars (various) for battery cells, and 10,000 porcelain insulators large size and 2,000 of smaller sizes as well as 7,500 zincs for Meidinger and 1,000 for Leclanché cells. Particulars from Die Königl. Magazin-Verwaltung, Dresden-Friedrichstadt.

Burnley.—The Corporation invite tenders for the supply and delivery at their electric lighting station, Burnley, of armoured concentric underground cables. Specification, schedule of quantities, and form of tender may be obtained on application to Mr. W. R Wright, borough electrical engineer, on payment of £1. 1s., which will be returned on receipt of a *bonâ fide* tender. Sealed tenders, endorsed "Tender for Cables," and addressed to the Chairman of the Electric Lighting Sub-Committee, Town Hall, Burnley, must be delivered on or before the 24th inst.

Paris.—Tenders are wanted by the French Government for the supply of a quantity of material for batteries (12 lots). Application should be made to La Direction générale des Postes et des Télégraphes, Paris, rue de Grenelle 103, and tenders must be in by June 16, but application for permission to tender must be made at once. Tenders are wanted for the supply of a dynamo for the municipal generating station at the Buttes Chaumont. Application for permission to tender must be made at the Hotel de Ville before June 14, and tenders must be in by June 17.

York.—The North-Eastern Railway Company require tenders for the following articles during six months ended December 31, delivered carriage paid at the telegraph stores at York: (1) telegraph apparatus; (2) telegraph wires and line stores.

Digitized by Google

Payment for each month's delivery will be made at the end of three clear months, or in cash less 2½ per cent. discount. Forms of tender may be obtained on application to Mr. Greaves, Telegraph Department, York, and tenders must be sent to the Secretary, York, sealed, and marked "Tender for Telegraph Stores," by noon on June 8.

Huddersfield.—Tenders are required for the supply and erection of a 92 unit direct-current dynamo and of a 3½-unit combined steam-engine and dynamo at Trafalgar Mills, Huddersfield, for Messrs. Learoyd Bros. and Co. Copies of specifications and general conditions can be obtained from Messrs. Shepherd and Watney, engineers, 71, Albion-street, Leeds, on receipt of a cheque for £1. 1s., which will be returned on receipt of a bona fide tender. Tenders, endorsed "Electric Lighting," must be addressed and delivered to Messrs. Learoyd Bros. and Co., Milnsbridge, Huddersfield, before noon on 19th inst.

Croydon.—The Corporation require tenders for the erection of a chimney shaft for the electric lighting station now being built in Factory-lane, Croydon, in accordance with drawings prepared by Prof. Kennedy, Old Queen-street, Westminster. The drawings and specification can be seen at the Borough Engineer's Office, 8, Katharine-street, Croydon, where also bills of quantities and form of tender can be obtained on payment of a deposit of £2. 2s., which will be returned to every person sending in a bona fide tender. Tenders to be sent to Mr. E. Mawdesley, town clerk, Municipal Offices, 8, Park-street, Croydon, by 11 a.m. on June 8.

Glasgow.—Tenders are invited by the Caledonian Railway Company for the supply of telegraph and electric appliances, etc., for 12 months from August 1, 1896. Specifications and forms of tender and any other necessary information may be obtained on and after June 1 from Mr. Jas Lorimer, superintendent of stores, Caledonian Railway, Charles-street, St. Rollox, Glasgow. Patterns may be inspected on and after June 1 from 9 a.m. till 5 p.m. at the Company's Stores, Charles-street, St. Rollox (Saturdays 9 a.m. till 1 p.m.). Tenders, endorsed "Tender for Stores," to be lodged with Mr. J. Blackburn, secretary, 302, Buchanan street, Glasgow, by June 15.

Leeds.—The City Council invite tenders for an electrical installation sufficient for the working by the overhead system of haulage, a double track of tramway seven miles long. The work will be divided into the following contracts: (1) poles for supporting trolley wire; (2) underground conduits and conductors; (3) trolley wire and attachments; (4) motorcars; (5) accumulators and switches; (6) steam engines; (7) dynamos, switchboards, and accessories. Tenders, endorsed with the number of the contract, must be sent in, addressed to the Town Clerk, Town Hall, Leeds, by June 20. Particulars, plans, forms of tender may be had (on payment of a deposit of £2 2s. for each contract, which will be returned on receipt of a bona fide tender) from the City Engineer, Municipal Buildings, Leeds; or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, S.W.

Shoreditch.—The Vestry invite tenders for the supply and fixing of insulated conduits, cables, switch and fuse boards, and all sundry fittings and materials for installing the electric light in their new dust destructor and electricity supply station, Coronet-street, Shoreditch. Specifications, with forms of tender, can be obtained from the consulting engineers Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, on payment of three guineas, which sum will be returned on receipt of a *bonâ fide* tender. Contractors whose tenders are accepted will be required to enter into a formal agreement, under seal, with sufficient sureties for the due fulfilment of their respective contracts. Trade union rates of wages and hours to be observed. Sealed tenders, endorsed "Electric Lighting—Tender for Wiring," to be sent by 4 p.m. on June 16 to Mr. H. Mansfield Robinson, clerk and solicitor, Town Hall, Old-street, E.C.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following: (*a*) the amount of capital which the applicants are prepared to subscribe; (*b*) the system which it is proposed to establish; (*c*) the mileage of lines to be laid; (*d*) the fares to be charged; (*e*) the frequency of the service; (*f*) the length of the license required by applicants; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about 12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

Bucharest.—The result of the enquiry into the tender of contracts held on March 14-26, 1896, having led to no definite approval, notice is given that a fresh enquiry will be held on June 12-24, 1896, at 10 a.m. in the Town Hall, Bucharest, when sealed offers and tenders will be received for the lighting of the outlying zone of the town, by such a system as will not necessitate any canalisation, and which may be adjudged to be most advantageous of all the systems proposed, with a view to replacing the 3,265 petroleum lamps now lighting the streets and squares of the outlying districts of the town. The enquiry will take place in accordance with the conditions of contract established by the management of the Public Works Department and approved by the Town Council at its meeting held on January 24, 1896. Particulars of the conditions may be obtained at the offices of the Agence Havas, 96, Queen-street, Cheapside, London, between 11 a.m. and 4 p.m. The contract will be granted for a period of five years dating from the time of its approbation and acceptance by the Board of Enquiry, or for a longer period, according to the proposals and conditions of tenders submitted. Competitors must indicate in their tenders the points provided for in clause 6 of the conditions of contract respectively. Intending competitors are requested to attend on the day and at the hour above mentioned at the Town Hall, prepared with a deposit in 15,000fr. in cash or in Government stock, to be placed in the Public Pay Office, in order to be admitted to take part in the competition.

RESULTS OF TENDERS.

Colchester.—The Town Council have accepted the tender of the Electric Construction Company to establish an electric light installation at £10,675. They are applying to the Local Government Board for power to borrow £15,000 for this purpose.

BUSINESS NOTES.

Lambeth.—The final contract between the Vestry and Mr. Sax will be brought forward at the next meeting of the Vestry.

Eastern Telegraph Company.—The receipts for the month of May were £73,853, as against £68,382 for the corresponding period of 1895.

Crompton and Co.—Mr. John Trotter has been elected a director of Crompton and Co., Limited, in the place of Viscount Emlyn, resigned.

St. Helens.—The Local Government Board have sanctioned the application of the Corporation to borrow £10,000 for electric lighting purposes.

Rotherhithe.—The Electric Supply Corporation have given notice to the Vestry of their intention to lay mains in Rotherhithe New-road and Bush-road.

Eastern Extension Telegraph Company.—For the month of May the receipts show an increase of £5,536 as compared with the corresponding period of 1895.

Lincoln.—The Corporation are applying to the Board of Trade for a provisional order enabling them to put in force the provisions of the Electric Lighting Acts, 1882 and 1888.

India.—It is stated that the temples of India are to be lighted with electricity, the example having been set by the great shrine of Siva, at Kochicaddie, near Mutwal, in Ceylon.

South Shields.—In St. Paul's Presbyterian Church a new electric organ has been erected on the Hope-Jones system. The cost of the organ and fixing was a little over £800.

Tighnabruaich.—The lighting of this place with electric incandescent lamps is a success, and a beginning will shortly be made to introduce the electric light into private houses.

Bristol.—The electric cars on the city and Kingswood line of the Bristol Tramways and Carriage Company, Limited, carried during Whitsun week a total of 122,065 passengers.

Middlesex County Council.—The Council have resolved not to sanction the erection of telegraph poles from the Edmonton boundary to the Ponder's End Post Office by the General Post Office.

London, W.C.—The Strand Board of Works have given permission to the Exchange Telegraph Company to run an underground pipe across the Strand from the Outer Temple to the Law Courts.

Manchester Electrical Works, Limited.—This Company has been registered to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, etc. The capital is £1,000.

Osborne.—The National Telephone Company have been directed to connect Osborne House with the telephone exchange system now being established between the various towns in the Isle of Wight.

Lee (Kent).—At the meeting of the District Board of Works a suggestion as to connecting the Board's offices at Charlton with those at Lee, at a cost of about £20, was referred to the local committee.

Newbury.—The Earl of Carnarvon has recently had the electric light installed throughout Highclere Castle and stables, powerful engines for driving the machinery having been erected in the rear of the castle.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending May 31 amounted to £1,809, as compared with £1,146 in the corresponding week of the previous year, being an increase of £663.

Wrexham.—The Board of Trade having a few weeks ago revoked the Wrexham electric light and power order, the Lighting Committee of the Town Council are considering the advisability of the Council obtaining an order.

Digitized by Google

Branksome.—On the recommendation of the Assessment Committee, the Poole Board of Guardians on Monday decided to sign a contract with Messrs. Castle and Castle for the revaluation of the electric light works at Bourne Valley.

Newhaven.—The Rural Council have decided to allow the Rottingdean roads to be opened for electric lighting purposes. Rottingdean parish adjoins Brighton, but this application was made by an electric lighting company.

Ealing.—At a meeting of the District Council Mr. Tidy asked when the accounts in connection with the electric lighting business would be ready. The Clerk replied that he hoped they would be ready by the next meeting of the Council.

Guernsey.—The High-street at Guernsey was temporarily closed on Wednesday whilst workmen removed all telephone wires, which, it is alleged, the National Telephone Company put up without the permission of the authorities, who object to lines crossing streets.

Telephonic Extension.—Norwich, Ipswich, Lowestoft, Yarmouth, and other important towns in the Eastern Counties, have been placed in direct telephonic communication with Bristol, Manchester, Birmingham, Sheffield, Leeds, Nottingham, Bradford, etc.

Electrical Copper Company, Limited.—This Company has been registered with a capital of £500,000 to acquire and work certain patents, patent rights, and inventions relating to the manufacture or treatment of copper and other metals by electrolysis.

Appointment Vacant.—The Leyton Urban District Council are prepared to receive applications for the post of resident engineer to the electric lighting installation now in course of construction. For particulars apply by letter to Mr. R. Vincent, clerk to the Council, Town Hall, Leyton, Essex.

Poplar, E.—The Board of Works have decided to apply to the Board of Trade for an extension of time in the matter of the Poplar electric lighting provisional order, and to approach the London County Council with a view of securing the supply of electricity for lighting the Blackwall Tunnel from the station of the Board.

City and South London Railway.—The returns for the week ended May 31 were £842, compared with £929 for the corresponding period of last year, being a decrease of £87. The total receipts for the half-year terminating as above were £20 535, compared with £20 533 in the same period of the preceding year, being an increase of £2.

Stockton.—The Corporation, being under an obligation to instal the electric light for public purposes or allow a private company to do so, are now applying to the Board of Trade for an extension of time, which would otherwise expire in August. At present the larger industrial companies and three or four tradespeople in the High-street have their own installations.

Peterborough.—Mr. Batten at the Town Council meeting objected to paying Dr. Fleming's account of £11. 14s. 6d. for attending the electric light enquiry unless and until Dr. Fleming made a report upon a scheme so that they could know what it was he proposed to do. He moved that the bill be not paid at present, but only two voted for the resolution, which was lost.

Tunbridge Wells.—At the request of the borough electrical engineer, the Watch Committee of the Town Council have agreed to instruct the chief constable to allow the police to turn off the arc lights and turn on the incandescent electric lights in the streets at midnight. The profit on the electric lighting amounts to £737 on the six months' working after allowing £50 to the rates for general establishment charges.

Worthing.—At the meeting of the Town Council the proceedings of the Electric Light Committee, who recommended that the town clerk should ascertain from the Board of Trade on what terms or conditions the Corporation might, if they so desired, obtain an extension of the period within which the works prescribed by their electric lighting provisional order are to be completed, were confirmed without discussion

Sale of Electric Plant.—Messrs. Percy Huddleston and Co announce in our advertisement columns the sale of the entire contents of the Acme and Immisch Electric Works, Ferdinand-street, Chalk Farm, N W. The sale, which comprises engines and boilers, dynamos and various meters and other electrical appliances, machine tools, office furniture, etc, will be held on the works, on June 16 next, at 10 for 11 o'clock.

The Edison Electric Illuminating Company of New York.—The gross earnings for April amount to 180 110dol, an increase of 16 700dol. as compared with the same month of last year, and net 90,584 lol., an increase of 12 899dol. For the four months ended April 30 the gross earnings were 777,670dol., an increase of 65,217dol as compared with the corresponding period of last year, and net 399,368dol., an increase of 56,786dol.

Manchester.—The special committee of the City Council appointed to consider the subject of the municipalisation of tramways report that, after full consideration, they are of opinion that it is desirable to allow the matter to remain over until nearer the termination of the first lease, which will expire on May 1, 1898, and that the Corporation should make application to Parliament for powers themselves to work the tramways of the city.

Pembroke.—A letter was read at the meeting of the Commissioners from the Board of Trade, dated May 19, informing the Commissioners that having received satisfactory reports from Colonel Yorke, R.E, and Major Cardew, R.E., the Board had certified the Dublin Southern District Tramways to be fit for public traffic, and had given a conditional consent to the use of electrical traction, limited for the present to a period of one month.

Birkenhead.—Mr. John Edwards enquired at the meeting of the Town Council when the Corporation electrical installation was likely to be completed. Alderman Deakin replied that there had been so many disappointments in this matter that he did not like to make any definite statement, but from a conversation he had with Mr. Shoolbred, the electrical engineer, he hoped that some portions of the district would be supplied with the service in the course of a few weeks.

Rochdale.—Sanction has been received from the Local Government Board to the contemplated borrowing of £500 for purposes of lighting the free library with electricity. The Library Committee have decided that the work should be proceeded with and that Messrs. Peers and Co., of Manchester, be appointed engineers in reference to the carrying out of the contract at a commission of 5 per cent. on the cost of the electric works, together with travelling expenses.

Hampstead.—At the Vestry meeting the Lighting Committee reported that they had given instructions for mains for the supply of electric current to private consumers to be laid in the following roads—viz., Greencroft gardens (from Finchley-road to Goldhurst-terrace) at an estimated cost of £125; Oakhill-park (portion west from Frognal), £28; Primrose Hill-road (from Fellows-road southward to parish boundary), £290; and Nutley terrace (Dalehamgardens), £52. The committee's action was approved.

Eccles.—The Town Hall and Electric Lighting Committee have accepted the offer of the National Telephone Company, Limited, to provide the telephonic communication required at the town hall, the cemetery, the fire station, the public baths, and the police station, for three years, at the annual rent of £43. 15s. Several large firms have indicated their desire to lay down installations, so that as soon as the Town Council can carry into effect their electric lighting order they will start with a very good demand. A Local Government Board enquiry has been held into the application by the Council to borrow £20,000 for carrying out the electric lighting scheme.

Sunderland.—The sub-committee having charge of the Corporation's electric light have decided to advise the reduction of the price of electric energy for motive purposes from 3½d per unit to 2½d. This is with a view of competing successfully with gas-engines as at 2½d. the cost will be about the same as that of gas. Some Wearside firms are already using electricity for running their machinery. The members also decided to recommend the Highways Committee to lay down additional feeders with a view to providing facilities for the ensuing winter.

Glasgow.—So far as can be judged, the present year's working of the electric lighting will result in a large surplus of revenue over expenditure. In view of this state of matters, the Electric Lighting Committee at their last meeting discussed a proposal to reduce the price to consumers, and it was suggested that the Brighton principle should be adopted. Under this a uniform charge is made for the first hour, after which a reduced scale comes into effect. The committee, however, decided to postpone a decision until the figures have been submitted.

Queen Anne's Mansions Lighting and Heating Company, Limited.—The trustees announce payment to the debenture-holders in cash for all the accrued interest, and a further cash payment for one moiety of the principal, the other moiety being satisfied by delivery of second debentures of the Queen Anne Residential Mansions and Hotel Company, Limited, bearing interest at 5¼ per cent. The old debentures, with all unpaid coupons attached, must be lodged at the office of the company, 251, Winchester House, three days before payment.

Dover.—The land wires for the new telephone cable between London and Paris being on the point of completion arrangements are being made to lay the cable across the English Channel at an early date. The cable will start on the English side from near Lydden Spout, about two miles westward of Dover, and between that town and Folkestone The cable will contain four wires, making two telephone circuits, which, with the existing cable, will provide four telephone services between the English and French capitals. The new cable will be used for simultaneous telegraphic and telephonic operations.

Douglas.—Special meetings of the Town Council have been held to take into consideration the question of assisting the Douglas Tramway Company to complete the upper Douglas tramway before the rush of the Manx visiting season The tramway company intended to have the tramway completed for the season, but difficulty after difficulty has had to be overcome. The Legislature has ordered that the busy thoroughfare of Prospect-hill shall be widened before the lines are laid along it. Unless, therefore, a great deal of property at present tenanted can be secured and cleared by the Town Council, the construction of the tramway cannot proceed this year without opening the principal streets in July and August.

Electric and General Investment Company, Limited.—The directors recommend a further dividend on the ordinary shares at the rate of 30 per cent. per annum for the six months ended May 31, making, with the interim dividend, 20 per cent. for the year, and they also recommend a dividend of £20 on each founders' share for the year. The trustees for the founders' share reserve fund propose to distribute to the holders of such shares a sum of £20 per share for the year out of the proceeds of investments sold and dividends received in respect of the founders' reserve fund, making a total distribution of £40 on each founders' share. The transfer books and register of members of the Company will be closed from the 5th to the 18th inst, both days inclusive, for the purpose of preparing the dividend warrants. The dividends, etc., are to be payable on the 19th inst.

Digitized by Google

Dundee.—At a special meeting of the Gas and Finance Committee it was reported that in the electricity department there was a profit of £1,126 15s. 1d. Treasurer Ritchie reported that there was a surplus for the year of nearly £5,000. He moved that meter rents should be entirely abolished in both the gas and electric lighting departments. He also proposed that the electric light consumer should get the same discount as the gas consumer. An amendment was moved that the electric meter rents should be adjusted simply to recoup the Town Council for interest on sinking funds and original cost. Treasurer Ritchie's motion was adopted by a majority of one, the resolution with reference to the electric light being passed by his casting vote. A conference has taken place between a sub-committee of the Works Committee of the Town Council and a sub-committee of the Harbour Board on the question of controlling by electricity the public clocks in the city, numbering 10, and including the three at the harbour. The Harbour Trustees unanimously agreed to recommend that the harbour bear its proportion of the first cost of the apparatus and the annual cost of upkeep and of supplying the current.

New Issues.—Accles, Limited, has been formed, with a capital of £400,000, to acquire the business of general engineers and manufacturers of motorcars, etc., now carried on at the Holford Works, Perry Barr, Birmingham.—British Thomson-Houston, Limited, has been formed with a capital of £240,000 to enter into and carry into effect an agreement to be made with the British Thomson-Houston, Limited, to acquire, work, develop, turn to account, and deal with any tramways, railways, electric works, telegraphs, telephones, etc., and to carry on the business of electricians, mechanical and electrical engineers suppliers of electricity, and manufacturers of and dealers in electrical apparatus. The registered office is at 38, Parliament-street, E.C.—The London Electric Omnibus Company, Limited, has been formed with a capital of £250 000 to enter into and carry into effect an agreement with Radcliffe Ward and with the Solar Accumulator Company; to carry on the business of an electric omnibus company; to construct, lay down, establish and fix the necessary apparatus; and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity, etc.

Exeter.—At the meeting of the City Council the Special Committee on Electric Lighting reported that it was necessary that the capacity of the works should be at once increased, and that the surveyor had stated that this increased power could be given either by steam or gas engines. A gas engine would be preferable for the purpose of giving an all night supply, and it was possible that it might also be found to be better to have the extra power entirely from gas-engines instead of fixing an additional boiler An additional alternator would also be necessary which might be driven either by a gas engine or by steam power and there must be an additional feed pump with steam and water connections. The committee recommended that they should be empowered to obtain prices of the two classes of machinery upon a guaranteed efficiency, and that upon receipt of the tenders they should recommend the acceptance of that considered most suitable. In moving the adoption of the report Mr. Domville said that as the Council took possession of the property on June 30, it was necessary for them to meet the increased demand for the light which would undoubtedly follow on their having committed themselves to a 24 hours' supply. Mr. Ham seconded, and the report was adopted.

Halifax—A few days ago a number of members of the Corporation, at the invitation of Alderman Woodhead, chairman of the Gas and Electric Lighting Committee, visited the electrical exhibition at Northgate Hall, and there partook of an electrically-cooked repast. A few brief speeches were afterwards delivered. Alderman Woodhead referred to the prejudices which had existed in Halifax with regard to electricity for even lighting purposes. He believed, however, that these were dying out. With regard to that day's experiment, they were now satisfied that they could cook by electricity, and to himself the result had been very agreeable. An hour before the meal the ovens used had never been tested at all. That, he thought, rendered the success of the experiment all the more satisfactory, and he understood that cooking by electricity could be accomplished at a fairly cheap rate. One advantage associated with it was that it could be carried on entirely without smell. Alderman Brook described the cooking they had experienced as perfect and mentioned that, as regarded the general use of electricity, the committee intended to supply the current continuously day and night. Councillor T. Greenwood, in adding his testimony, spoke of the wonderful developments being made in electricity. He was of opinion that, in many instances, it would supersede gas, and especially for small motors.

Cheltenham.—At the meeting of the Town Council the electrical engineer reported that within the next few months about £14,200 would be required to defray all actual expenditure contemplated and incurred up to the present time. The Electric Lighting Committee had decided that the whole extension from Manchester-street sub-station to High-street and Cambray sub-stations should be proceeded with at the estimated cost of £810, and that the extension to Lansdown-place sufficient to supply Trelawn be proceeded with at the estimated cost of £310. The borough engineer had submitted a design of a pillar for the incandescent electric lamps for street-lighting, which the committee had approved, and of which they had instructed the borough engineer to obtain tenders for a supply for as many as would be required for the Bath-road. An application from the electrical engineer for an increase of his salary was considered, and it was resolved to increase his salary to £260 per annum from June next, to increase each year by £20 up to £300 per annum, and that his department be independent of any other department, and that he alone be absolutely and directly responsible to the committee. Alderman Norman mentioned that the sanction of the Local Government Board had, after eight or nine months' delay, been received for loans amounting to £25,000 for extensions of the electric light undertaking.

Fife.—At the last meeting of the Telephone Committee of the County Council the chairman, Mr. H. V. Haig, said the first matter for consideration was the agreement (brought up by Mr. J Budge at a previous meeting) with the National Telephone Company, according to which they could put wires on the present poles. Mr. W. D. Patrick, clerk, stated that the agreement was made in 1885, and he read a letter from the Telephone Company, in which they admitted that additional wires could be erected by the Council on some of the poles. He thought they would find it difficult to impose the obligation, as the telephone system was now the property of the Post Office. Mr. Patrick stated that he had been looking into Acts as to the powers of the Post Office, and thought there was no doubt about the Council having the right to erect a telephone system. On the recommendation of Mr. Budge, Mr. Patrick was instructed to intimate to the Telephone Company that they had been too late in giving notice of the termination of the present agreement, and that it would continue for another year The Chairman stated that he had received a letter from Mr. L. Alwyn, Victoria street, London, in which that gentleman stated that he would be very glad to make an offer for the erection of a telephone system if the Council agreed to have one Mr. Alwyn assured him that it could be done at a very much cheaper rate than he had estimated, and he had in his employment Mr. Gardner, who had done all the work for the Telephone Company.

Liverpool—The sub-committee recently appointed by the City Council to examine the question of the lighting of the city, which has of late years been a matter of considerable local agitation, have presented an exhaustive report. The impression in the public mind has been that the charges for gas supplied by the Liverpool Gas Company are excessive in comparison with the charges in other cities, and there have been expressions of feeling that the works of the gas company should be acquired by the Corporation, and that the question of gas supply should become a matter of corporate undertaking. The sub-committee, after detailing their investigations, report that their conclusion is not in favour of entertaining the purchase of the gas company, but they recommend a closer oversight of the gas supply in the interests of consumers They suggest that the consumers should have a voice in the management, which could be effected by the appointment to the Board of the gas company of two or more members of the Corporation; but it seems quite open to question whether this would have the desired effect. At the meeting of the City Council, Alderman Walker, as an amendment to the general proceedings, proposed that a resolution approving of the plans and elevations of a building proposed to be erected by the Liverpool Electric Supply Company in Paradise-street, be referred back for further consideration. His principal objection was to the erection of two gateways facing Paradise-street, which he considered would be dangerous to the pedestrians. The town clerk read a memorial signed by residents and business men in the neighbourhood of Paradise-street, protesting against the erection of the proposed works. Mr. W. H. Watts seconded, but the amendment was lost by 57 votes to 18.

Leeds—The Yorkshire House to House Electricity Company recently made an offer to the Corporation to supply the current required for the proposed electric trams between Roundhay and Kirkstall The company, it appears, are willing to instal at their works in Whitehall-road the special plant required to deliver current at a suitable pressure, and to accept a contract for a short period to supply this current at 2·3d. per unit, assuming the quantity consumed to be about 300,000 units per annum. They explain that the price named is capable, under certain conditions, of very material reduction, as it is largely made up of the necessary provision for loss in the event of the specially provided plant being thrown on their hands at the end of the period. The price might, therefore, be greatly modified by extending the term of the contract, or by the consumption being larger than the company's rough estimate It is suggested, as an alternative, that the Corporation might provide the special plant and apparatus required, all of which would be easily portable and suitable for use when the permanent generating station was erected. In this way, also, a large reduction in the price could be effected, and the duration of the contract curtailed within very reasonable limits. The company urge that they are enabled by their large output to undertake the supply of energy at a price which is certainly as low as could be hoped for in works specially erected for the purpose, and they further point out that, by the acceptance of their offer, the Corporation would secure a minimum of risk and also be in a position, when extending their electric tramway system, to take advantage of any improvements in apparatus that might be effected in the meantime, or that might suggest themselves as the result of their experience.

Oldham.—At a special meeting of the Electric Lighting Committee the deputy town clerk read the statement of accounts of the Electric Lighting Committee for the year ended March 25 last, as follows: "The expenditure on capital account has been—engines and dynamos, £2,060. 18s 7d; batteries, £329. 17s. 7d; switchboard, £346. 13s 9d.; steam-pipes, etc, £155 16s 11d.; sundries, £37. 19s. 10d.; street mains, £3,358. 2s. 4d.—total, £6 289. 9s. The gross revenue for the year amounted to £3,847. 13s. 4d., and expenditure £1,577. 17s. 9d., the balance carried to net revenue account being £2 269. 15s. 7d. The interest on loans amounts to £813. 8s. 4d., and sinking fund account instalment to

Digitized by Google

£608. 12s. 7d., the net profit for the year being £847. 14s. 8d. The balance brought forward from the previous year is £902 3s. 7d, making the amount to be carried forward to the credit of next year £1,749 18s. 3d. The price of energy supplied to all consumers has been 6d. per unit during the whole of the year. The minimum quarterly charge for energy was reduced from 10s. to 5s. from June 25 last, and the charges for meter rent were also reduced from that date. The committee have also decided that from and after March 25, 1896, the price for current used by private consumers in excess of two hours' daily average maximum demand should be reduced to 4½d. per unit, and for all current consumed by public street lamps to 4d. per unit. The amount of energy generated has been 179·966 units, of which 147·432 units have been sold, being increases over the previous year of 93·599 units and 78·434 units respectively. The number of lights supplied on March 25 last equivalent to 8 c.p. was 11,830, being an increase during the year of 4 890. The number of consumers added had been 58, and additional meters fixed 63. The number of consumers on March 25 was 113, and the total number of meters fixed 125 The maximum demand was on January 6, the load at the station being indicated at 251 kilowatts, as compared with the previous year of 135—an increase of 116. The greatest quantity supplied in 24 hours was on January 6, being 1,232 units, against last year 641—an increase of 601. An application for additional borrowing powers to meet the growing demand for the light has been acceded to by the Local Government Board to the extent of £15,000. Two additional engines and dynamos, each of 200 h.p. capacity, have been placed in the station, and the supply mains have been extended a distance of 1,187 yards. The total length of mains laid on March 25 was 5,763 yards. A sum of £500 received from the Gasworks Committee has been paid to the Sanitary Committee towards the cost of erecting a new chimney at the destructor works adjoining the supply station, and they in return have agreed to supply you with the surplus steam generated there, which it is expected will effect a material reduction in the cost of generation." The committee considered the report highly satisfactory, and it was accepted and ordered to be printed.

Edinburgh.—At the last meeting of the Corporation Mr. Mackenzie gave in a report by the Electric Light Committee, which recommended that as from May 15 the charge for electric energy be 5d. per unit, the charge for each public lamp £18 per annum, and that there be no meter rents. In doing so he stated that the electric lighting station was opened on April 11, 1895, with 48 private consumers, with lamps equivalent to 2,000 8-c.p. lamps connected. On May 15, 1896—after 13 months' working—there were 425 consumers with lamps equal to 54,360 of 8 c.p, and 247 public arc lamps equal to other 4,500—making a total on May 15, 1896, of equal to 58,860 8-c.p. lamps in all. The plant was put down for a total of 40,000 lamps connected, and it was thought that this would serve for two or three years before extensions would be required, but at Christmas every engine and boiler in the station were fully loaded, and the engineers had a very anxious time of it. For fear of a breakdown they had been obliged to borrow an engine from one of the London companies, the demand having come so suddenly that there was no time to get one of their own. Fortunately, no breakdown took place. In order to be able to cope with no doubt a very largely increasing demand next winter, five boilers, six low tension engines of 360 h.p. each, a number of high-tension machines, and other items of plant were on order and would be ready to run about the end of September, more than doubling the capacity of the station. The necessary extensions of mains were being carried out, and new consumers were being joined on daily. The prospects of the undertaking were therefore very promising from the engineering and demand point of view, and he was very glad to be able to say that the financial result of the past year and prospects of the current year were equally good. Commencing with a small load and having not only a full staff to keep up but heavy standing charges to meet, they were for 5½ months working at a loss, the turning point being about September 26. From that point to April 16 they made their income for the year. They were now again working at a loss, so that making their report for 13 months was a disadvantage, the loss from April 11 to May 15 having been about £200. The total income for the 13 months from private lighting was £13,220 18s. net, after allowing the discounts and for this they sold about 550,000 units. The total from public lighting was £3,604 and the units sold were about 320,006; total, 870,000 units sold during the 13 months, giving an income of £16,824. The total station expenses had been about £4,700, and this included carbons, trimming arc lamps, and upkeep of mains. The standing charges, interest, and contribution to sinking fund amounted to about £8,100, making altogether a total charge of about £12,800, thus leaving a balance of about £4,024. This was a most satisfactory state of affairs, and, as far as he knew, was a "record" for a first year's working. The Manchester installation—one of the most successful in the country—having a clear surplus the third year of its working of about £11,000), had for its first year a deficit of £210. The engineers estimated their income from May 15, 1896, to May 15, 1897, at £28,100 counted at present rates, and their total expenditure at £21,122, leaving a balance of £6,978. The Electric Lighting Committee thought that it would not only be fair to the consumers, but that it would be the best policy for the Corporation to reduce the charge for lighting from 6d. to 5d. per unit, the charge for motors from 3½d. to 3d., abolish meter rents altogether, and reduce the charge for public lighting from £20 to £18 per lamp. This would reduce the estimated income by about £4,100, but still leave an expected balance of £2,878. His own opinion was—and it was also the opinion of the engineers—that their balance would be very much larger, for he believed the effect of the reduction in price would be that a great many more consumers would come on, and that more current would be used per lamp. They had been very fortunate in their selection of Prof. Kennedy as their consulting engineer, a man of the very highest standing, and they had loyally followed his advice. They were also fortunate in their late resident engineer, Mr. Monkhouse, who worked with extraordinary energy. He had no doubt Mr. Newington would prove a most competent successor. The Corporation were also indebted to the other members of the staff, who had well supported their superiors.

Brighton.—An important enquiry has been held by Colonel John Ord Hasted, R.E., Local Government Board inspector, into the application of the Town Council for sanction to borrow £35,900 for the purposes of electric lighting within the borough. The Corporation were represented by Mr. W. P Boxall, instructed by the Corporation solicitor (Mr. H. Talbot), who with the town clerk (Mr. F. J. Tillstone) was also in attendance Mr. F. J. C. May (the borough engineer and surveyor), Mr. A. Wright (Corporation electrical engineer), and Mr. Stevens (borough accountant) were also present. Mr. Boxall said he thought some particulars as to the progress of the Corporation undertaking would be acceptable to the inspector On March 23, 1892, then, the number of consumers of electricity was 110; on the same date in 1893 it was 226; in 1894, 454; in 1895, 872; and in March of this year there were no fewer than 1,121 consumers in the borough. The quantity of electricity sold, as perhaps might have been expected, showed an equal, or even larger, proportionate increase. Taking the figures for the months of January and February in each year, they found that whereas in 1892 the total number of units sold was 22,000, in 1893 it was 44,000; in 1894, 78,000; in 1895, 148 000; and this year, 228,000. Exclusive of the cost of the coal, which was a matter of geographical consideration, some of the northern towns getting their supply almost at the pit's mouth, the cost of the production of electricity in Brighton was lower than in any other town in England. It was obvious, having regard to the increases in the business of the undertaking to which he had referred, that they must require an extension of their plant, more especially as the Corporation had resolved to supply electric lighting throughout the streets of the town, and a considerable portion of the loan now asked for would be expended in this direction. The loan also included £2,300 overspent on proposals of street-lighting previously sanctioned. With regard to the financial position of the borough, Mr. Boxall further submitted a statement prepared by the borough accountant, which showed the estimated total ratable value of property in the borough to be £756,507, the net value for the purposes of the general district rate being £734,868. The nominal amount which a penny rate would produce was £3,061, the net yield, after deducting the usual allowance, being £2,900. The present indebtedness of the Corporation under the Sanitary and Public Health Acts was £352,113. 5s. 10d., the indebtedness on the electric light account being £129,454. The assessable value of the town for two years was £1,469,737. Mr. Arthur Wright also gave particulars of the proposed extensions, observing as to the street-lighting that the idea was to have public electric lighting in every street where the Corporation mains were laid. With regard to the sum of £2,300, that was partly due to the cost of the new lamp standards. They had been estimated to cost the same as the standards on the King's-road, but the contractor would not supply them at the price, and instead of £16 each, they actually cost £35. Then, again, the Council decided to run 10 more arc lamps during the year than they had estimated for. The works to be done included extensions and new machinery, new mains, house services, etc. Mr. Boxall here interposed a statement of the profits of the undertaking. In 1894 there was a profit made of £4,400, of which £3,000 was placed to the reserve fund and £1,400 went in relief of rates Upon that the price of electricity was materially lowered, making a difference of £6,000 in the returns and yet in 1895 a profit of £1,150 was made. But for the reduction in price it would have been £7,500. The Inspector: What is your present charge? Mr. Wright: Sevenpence for the first hour and 3d. per unit afterwards. The average price we obtained last year was under 4¾d per unit, or lower than in any other town. Mr. May also explained the various plans which were put in, and the enquiry then terminated. The Works Committee have received a letter from the Solicitor's Department, General Post Office, with reference to the Council's refusal to grant permission for the erection of an overhead telegraph wire across Standford-road, and pointing out that the department could refer the difference under the Telegraph Act to a magistrate or county court judge with an appeal to the Railway Commissioners. The committee instructed the town clerk to reply stating that the Council consider telegraph and other wires carried over the streets in the borough are very objectionable; that they are willing, as on previous occasions, to grant the Postmaster-General facilities for carrying the wire underground across the street, as all the existing telegraph wires in the borough (with two or three exceptions) have been laid, and that the Council hope the Postmaster-General will not further press his application for permission to carry wires overhead in Brighton. The electrical engineer's recommendation to the Lighting Committee to run a supply main to the Prestonville district at an estimated cost of £1,600 has been approved, and the committee have decided that so soon as the mains are laid the street lamps along the line of route be lighted by incandescent electric lamps instead of gas An additional lamp is to be erected in Steine-lane, and the position of the existing lamp altered; an electricity main is also to be laid in Steine-lane, and the two public lamps to be erected in that street are to be lighted by electric incandescent lamps.

PROVISIONAL PATENTS, 1896.

MAY 26.

11387. An improved electrical locking and unlocking railway signal apparatus. Adam Garson Horne, 154, St. Vincent-street, Glasgow.

11391. Improvements in cut-outs for electrical uses. John Clarkson Reynolds, Prince's-chambers, Wolverhampton. (Complete specification.)

11413. Improvements in pneumatic telephones. John Charles Chalmers, 62, St. Vincent-street, Glasgow.

11417. Improved means for electrically connecting the rails or sections of electric railways. Robert Calthrop Brown and Franklin Elias Huntress, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

11419. Devices for electrically lighting the wick of oil lamps. Hugh Donald Fitzpatrick, 70, Wellington-street, Glasgow. (The Empire Self-Lighting Oil Lamp Company, United States.) (Complete specification.)

11421. Improvements in dynamos and electromotors and in the gearing of same. Joseph Devonport Finney Andrews, 45, Fulham Park-gardens, London.

11429. Improvements in and connected with electric brakes for electrically-propelled vehicles. The British Thomson-Houston Company, Limited, 70, Chancery-lane, London (William B. Potter, United States.) (Complete specification.)

11441. Improvements in electric arc lamps. Thomas Edgar Adams, 18, Buckingham-street, Strand, London. (Complete specification.)

11451. Improvements in apparatus for producing musical sounds by electricity. William Phillips Thompson, 322, High Holborn, London. (George Breed and Charles Addison Bragg, United States.) (Complete specification.)

11471. Improvements in arc lamps for alternating-current circuits. William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Alexander Barnhill Fernald and John Henry Hubbell United States.) (Complete specification.)

11473. Improvements in electric railways or tramways. John Charles Love and John Earle Hodges, 45, Southampton-buildings, Chancery-lane, London.

MAY 27.

11481. Improvements in the driving of machinery, vehicles, boats, etc., by electric motors or other high-speed motors. Thomas Tomlinson, Ballywaltrim Cottage, Bray.

11517. Improvements in or relating to the application of electric light to carriage or other lamps. Herbert Alfred Bessemer, Bernard-street, Southampton.

11519. Improvements in or relating to induction coils, alternating-current motors, transformers, dynamos, and other machines depending upon the principle of electrical induction. Richard Joseph Crowley and Alfred Blandford Hutchings, ———.

11520. A new electrical signal of the signal-house at the railway station. Wilhelmine Magaretta Klees, 126, Carlton-vale, Maida Vale London.

11552. An improved means for switching current, applicable for electric motorcars operated by a mixed supply. Clemens Adam, 6, Lord-street, Liverpool. (Complete specification.)

11553. Improvements in the manufacture and production of filaments for incandescent electric lamps. Joseph Wilson Swan, 47, Lincoln's inn fields, London.

MAY 28

11617. An improved electric alarm for railway trains and other purposes. Henry Binko, 34, Leadenhall street, London.

11627. Improvements in secondary batteries. Ernest John Clubbe, Alfred William Southey, and the Electric Motive Power Company, Limited, 55, Chancery-lane, London.

11647. Improvements relating to electric couplings. Emma Theodora (Lady Forbes), 45, Southampton-buildings, Chancery-lane, London.

MAY 29.

11710. An improved electrical method of joining metallic and other tubes, pipes, bars, and the like. William Leannard Poole, Alfred Stone, and Alexander St. Vincent Turquand, 168, Fleet-street, London.

11724. Improvements in the manufacture of electrical hot-plates and other apparatus designed for electrical production of heat. Albert Ernest Woodhouse, 7, Staple-inn, London.

11730. An improved apparatus for producing galvanic or electrolytic depositions. Williams Phillipe Thompson, 6, Lord-street, Liverpool. (The Elektra Galvanoplastische Anstalt, H Teith, and A. Floeck, Germany.)

11732. An improved plate for storage batteries. Franz Grünwald, 6, Lord-street, Liverpool.

MAY 30.

11813. Improvements in or relating to electric cables. William Arthur Price, 55, Chancery-lane, London.

11779. Electric arc lamp. James Grieve Lorrain, Norfolk House, Norfolk-street, London. (James McLaughlin, United States.)

11783. Improvements in electric railways. Henry Harris Lake, 45, Southampton-buildings. Chancery-lane, London. (Galilec Ferraris and Ricardo Arno, Italy.)

11800 Improvements in coin-freed electric meters for the measurement of electricity. Jacob Atherton, George Knight, and George Ellis, 70, Palace-chambers, Westminster.

11801. Improvements in sockets or holders for electric incandescent lamps. J. Katzenstein, 23, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1893.

13066 * Incandescent lamps. Boult. (Steuer.) (Amended specification.)

1895.

9144. Electric soldering apparatus Binswanger and Ball.

9146. Arc lamps. H. and R. Niewerth.

10302. Laying submarine electric cables. Snell.

12187. Telephonic apparatus. Holden

12414 Electrically lighting vehicles. Niblett.

12683. Telephone transmitters. Berdell.

13014. Dynamos and electric motors. New and Mayne.

20923 Electric annunciators. Thompson. (Higgins.)

1896.

1344. Securing electric insulators, hooks, etc., to walls, girders, etc. Beaujean.

3091. Accumulator batteries. Linde.

4806. Magnetic separators. Weatherill.

5389. Autographic telegraph apparatus Jackson. (Etheridge.)

6048. Controllers for electric motors Devonshire. (Potter.)

6208. Electric switches. Ballance and Hewson.

6487. Controllers for electric motors. Devonshire. (Priest.)

NOTES.

Run and Read.—This is neither a souvenir nor a premature number, nor an attempt to stop the issue of a report in our contemporaries; it is merely a sample of our usual enterprise. "Eclipse first—and the rest nowhere."

Personal.—Mr. R. P. Wilson, of 3, Princes-mansions, Victoria-street, S.W., has severed his connection with the British Thomson-Houston, Limited, and proposes to continue the consulting work in which he has been engaged for some years.

Colliery Traction.—It is stated that the electric locomotives used in the Marles Colliery in the Pas-de-Calais weigh three tons each and draw three cars, holding each 15 tons of coal, at the rate of 10 miles an hour. They replace 30 horses.

Long-Distance Power Transmission.—The Lowell (Michigan) and Grand Rapids power-transmission line is 18 miles long. The pressure is as high as 10,000 volts (alternating), and the power is derived from turbines on the Flat River. About 200 kilowatts are transmitted.

North-East Coast Engineers.—We have received volume xii. of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders, covering the meetings from January to March, 1896, and containing important papers on the vibration of steam-engines.

Manila Rope.—We have received from the C. W. Hunt Company, of Broadway, New York, a well-got-up descriptive account of their manila rope, its manufacture, and the method of using it. In an appendix there are useful tables and formulæ relating to rope driving, and a reprint of Mr. Hunt's paper on that subject read before the American Society of Mechanical Engineers.

The Coming Week.—This evening (Friday) there is a conversazione at the Central Technical College, Exhibition-road, South Kensington, at 8 p.m. On Saturday the Institution of Electrical Engineers have a students' visit to the Bankside station of the City of London Company at 7.30 p.m. The Chemical Society meets as usual on Thursday, and next Friday Mr. Martin gives the "discourse" on Niagara at the Royal Institution.

Meteorological Society.—At a meeting of this society at the Institution of Civil Engineers at Great George-street, Westminster, on 17th inst., at 7.30 p.m., the following papers will be read: "Arctic Hail and Thunderstorms," by Henry Harries, F.R.Met.Soc.; "Climatology of Valencia Island, co. Kerry," by J. E. Cullum, F.R.Met.Soc.; and, if possible, also "The Winter Climate of Egypt, based on Results from Self-Recording Instruments, 1893-6," by H. E. Leigh Canney, M.D.

Rontgen Radiations.—Dr. John Macintyre has been trying to polarise Röntgen radiations by means of tourmaline, and cannot get any evidence of a polarising effect. He used a coil giving a 6in. spark, tourmalines 2mm. thick, and adjusted his vacuum to the point at which a maximum fluorescence was obtained. Prof. Haga, of Groningen, finds that the new radiations diminish the electrical resistance of selenium. With the particular tube he used the effect was about half that of full daylight.

Rainmaking.—The drought which prevailed up to last week has caused Mr. S. F. Walker to write to a Cardiff local paper to suggest that something may be done in the way of producing rain by electrical means. Mr. Walker's idea is practically embodied in the following question: "Why should we not cause an aggregation of the particles of moisture about the particles of dust, followed by deposit in the form of rain, by producing an artificial disturbance of the electrical conditions present in the atmosphere?" It is rather hard on the provincial editor to ask him such a question as that.

Electricity on the Stage.—In a brief article on the use of the electric light for the production of stage effects *L'Energie Electrique* says that nothing hitherto produced in this way can compare with what was done at the Drury Lane pantomime last winter. By the lavish use of incandescent lamps "the effect obtained was absolutely marvellous." It may be worth notice that our contemporary reproduces with suitable acknowledgement the illustrations of Cinderella's car and the transformation scene which appeared at the time in the *Electrical Engineer*.

New Lamps.—According to the New York *Electrical Review*, Mr. Tesla has been suffering from influenza. Nevertheless, he has been interviewed on the subject of Mr. Edison's new lamp. All that could be got out of him, however, was that "he had the utmost faith in the genius of Mr. Edison." From the discussion on Mr. Macfarlane Moore's paper at the American Institute of Electrical Engineers, it would appear that, so far as measurements have been made, the general opinion is that Mr. Moore's long Geissler tube lamps are not so efficient as the ordinary carbon filament.

Society of Engineers.—A visit was made by a large party of the members of the Society of Engineers on Tuesday to the Surrey Commercial Docks, Rotherhithe. Among those present were Mr. W. Worby Beaumont vice-president; Mr. Henry Adams, Mr. Joseph Bernays, Mr. A. T. Walmisley, and Mr. J. W. Wilson, jun., past-presidents; Mr. George Burt and Mr. Percy Griffith, members of council; Mr. Perry F. Nursey, hon. secretary and treasurer; Messrs. D. B. Butler, W. G. Cooke, H. Conradi, S. N. Glass, B. D. Kershaw, R. St. George Moore, H. Stanton, and Mr. G. A. Pryce Cuxson, secretary.

National Telephone Company.—This company have had their wires cut in Ludlow by the Ludlow Corporation's workmen, in consequence of their refusing to enter into an agreement with the Town Council in reference to fixing their lines. The owners of the other wires paid the required sum asked by the Corporation. They have also been cast in damages to the extent of £36, in the Dublin Courts, owing to one of their linesmen when engaged in making repairs dropping a saw on the head of a schoolboy, named Tuohy, who was passing underneath their poles at Killiney. But that is a thing that might happen to anyone.

New F.R.S.'s.—At the annual meeting of the Royal Society for the election of Fellows held last week, the following were elected into the society: Lieut.-Colonel Sir George Sydenham Clarke, R.E., Mr. J. Norman Collie, Ph.D., Mr. Arthur Matthew Weld Downing, D.Sc., Mr. Francis Elgar, LL.D., Prof. Andrew Gray, Mr. George Jennings Hinde, Ph.D., Prof. Henry Alexander Miers, Mr. Frederick Walker Mott, M.D., Mr. John Murray, Ph.D., Prof. Karl Pearson, the Rev. Thomas Roscoe Rede Stebbing, Prof. Charles Stewart, M.R.C.S., Mr. William E. Wilson, Mr. Horace Bolingbroke Woodward, F.G.S., and Mr. William Palmer Wynne, D.Sc.

New York Electrical Exposition.—The New York journal *Electricity* says the electrical exhibition was designed on popular rather than technical lines, and "from the popular or public point of view the exposition has been an instant success. The electrician, to whom many if not all devices are already known, may find less of interest than will the layman, but this is no fault of the exposition—the members of every trade or profession know more of its progress and development than do the outsiders. The exposition was designed on popular rather than technical lines, otherwise the interest which

Digitized by Google

it has aroused would not have been so general, neither would it be possible to sustain it for so long a period as four weeks."

The Post Office Committee.—Mr. W. H. Preece has been giving evidence before the Inter-Departmental Committee on Post Office Establishments. Mr. Preece was examined by Lord Tweedmouth, and said that all telegraphists had to possess a knowledge of electricity as applied to telegraphy and telephony. Increased knowledge tended to the efficiency of the service, and whatever tended to increase the efficiency of the service meant increased business. The Department did all they could to promote education among the men. As to promotion, there was nothing to prevent a linesman from becoming an engineer-in-chief. In answer to Mr. Spencer Walpole, Mr. Preece said there was no truth in the statement that men were promoted because they happened to be sons of the heads of departments.

The London University Question.—Dr. Collins has replied in the *Times* to Dr. Silvanus Thompson's letter. He says, and quotes Sir John Lubbock in support of it, that Convocation ought be consulted on the reorganisation scheme. But "under the present charter no machinery is provided for the expression of the opinions of all members of Convocation on any matter except the election of a Fellow." "Any canvass of the whole of Convocation on the question of reconstitution of the university must, therefore, be unofficial, and that which was made by Mr. Bompas and Dr. Napier was, of course, unofficial, but I certainly understood that the issue of the circulars and postcards was purposely delayed so that they might be first submitted to the Lord President of the Council and the member for the university, for any suggestions or alterations they might desire to make."

Gas and Air Mixtures.—A printed summary has been forwarded us of a lecture delivered by Prof. Frank Clowes on Tuesday before the Gas Institute on the subject of explosive mixtures of combustible gases with air and the methods of detecting them. Besides the actual explosive mixture, the products of explosion or incomplete combustion are considered. It has been long known that though immersion in an atmosphere of carbonic acid produced instant death, that gas was by no means fatal if a reasonable proportion of oxygen is present, while carbonic oxide, which forms a large proportion of producer and Dowson gases, acts like a poison, so that very small quantities of it are fatal. A curious fact brought out is that a mouse is much more sensitive to the action of this gas than the human subject, and that if one is carried in a wire cage where the presence of carbonic oxide is suspected, warning will be given sufficiently quickly to allow of retreat.

The German Electrical Engineers.—The programme and arrangements for the fourth annual meeting of the Verband Deutscher Elektrotechniker at Berlin next week are, except so far as concerns some of the subjects to be discussed, given in the *Elektrotechnische Zeitschrift* for June 4. A council meeting is to take place at the Architektenhaus at 10 o'clock on Wednesday, June 17. In the evening there is a reception at the Reichshalle, Leipsigstrasse. On Thursday, at 10 o'clock, the presidential address is delivered at the Architektenhaus. After this the secretary's and treasurer's reports are to be taken and the committee's reports presented, including one on safety rules, and the announcement of the award of the prize for non-interchangeable fuses. The committees for next year will then be appointed. In the evening there is a dinner at the Kaiserhof. On Friday there will be visits to various works and to the exhibition. On Saturday there is again a meeting at the Architektenhaus, when the officers and council will be appointed and the arrangements for the next year settled.

The Greenwich Observatory.—The annual visitation of the Royal Observatory took place on Saturday afternoon, when the Astronomer Royal, Mr. W. H. M. Christie, presented his report of a year's work to the Board of Visitors. From this it appears that the usual magnetic observations have been made during the year, the mean declination for 1895 being 16° 57·4′ west. Uncertainty attaches to the results of the mean horizontal force owing to the permanent effect of the iron in the new altazimuth pavilion, and the results of the magnetic dip are affected to the extent of about 3′ or 4′ for the same reason. An independent determination at a place sufficiently removed from this building is urgently required, but the question has been deferred pending the settlement of the site for the new magnetic building. During the year there were no days of great magnetic disturbance. The spot activity of the sun has steadily declined from the date of the last report, and on five occasions during the months of April and May, 1896, the sun was entirely free from spots—a state of affairs which last took place on March 28, 1891.

Institution of Civil Engineers.—The tabular statement of transfers, elections, deaths, and resignations during the year shows an effective increase of 109 on the previous total of 5,921, while the number of students was 877 as against 816 at the corresponding period of last year. The gross numbers on the books on March 31 in 1895 and 1896 were 6,737 and 6,907 respectively. At the annual general meeting, on Tuesday, the council for the session 1896-97 was duly elected, when several members were placed on the governing body as representative of the profession outside the United Kingdom. The full list of this new council is: President, Mr. John Wolfe Barry, F.R.S.; vice-presidents, Mr. W. H. Preece, F.R.S., Sir Douglas Fox, Mr. James Mansergh and Mr. William Anderson, D.C.L., F.R.S.; other members: Mr. A. R. Binnie, Mr. Henry Deane, Mr. W. R. Galbraith, Mr. George Graham, Mr. J. H. Greathead, Mr. J. C. Hawkshaw, Mr. Charles Hawksley, Mr. John Hopkinson, jun., D.Sc., F.R.S., Mr. A. B. W. Kennedy, LL.D., F.R.S., Mr. John Kennedy, Mr. G. Fosbery Lyster, Sir Guildford L. Molesworth, Sir Andrew Noble, F.R.S., Mr. William Shelford, Mr. B. B. Stoney, LL.D., F.R.S., Mr. F. W. Webb, Sir W. H. White, F.R.S., and Sir E. Leader Williams. Of these gentlemen Mr. Henry Deane represents Australia, and Mr. John Kennedy, Canada.

Trunk-Line Telephones.—We are constantly hearing of the progress made in connecting up the larger towns in this country by trunk-line telephones. Yet it does not quite seem that all is for the best in the best of all possible services. Anyhow, there are clients who are still dissatisfied. If the following is an example of the sort of thing that goes on, this is perhaps explicable. Messrs. Mellors, Basden, and Mellors, of Nottingham, write to the *Times* to say: "We yesterday had occasion to telephone to Birmingham. After conversing for about one minute the girl at the post office telephoned, 'Time up.' We thereupon asked for a second three minutes, stating that we would pay for it. The answer was, 'You must ring off, and telephone to the National Telephone Company again for them to ask us to put you in communication. This meant a further half-hour in getting through by the exchange between here and Birmingham. We to-day wanted to converse with Mansfield, and after one minute's conversation, owing to one of the principals having to be called to the telephone, the Post Office again informed us

Digitized by Google

'time was up,' and they could not allow us to continue the conversation, but we must ring up again. On complaining to the National Telephone Company, they inform us that from June 1 the Post Office authorities have taken over the trunk lines. We have never had this difficulty before, and it practically renders the telephone to long distances almost useless for business purposes." Of course, a customer could not be allowed to monopolise the wires for an indefinite time, whatever he was willing to pay ; but if a speaker has to wait half an hour to send his final half-dozen words over the wire, he will probably prefer to write or telegraph.

The Royal Society.—The second reception of this society for the present season was held on Wednesday night at Burlington House, when a large assemblage of guests were received by Sir Joseph Lister, president, and Lady Evans, wife of the treasurer. There was a very large and interesting collection of scientific exhibits. Mr. Herbert Jackson demonstrated the use of phosphorescent materials in rendering Röntgen rays visible, and Dr. John Macintyre exhibited three series of photographs taken by the rays, including photographs of soft tissues, a series including neck, tongue, larynx, heart (normal and abnormal), diaphragm, muscles, etc. Prof. Silvanus Thompson had also some very beautiful experiments and demonstrations with these rays, including the production of electric dust shadows. One of the finest exhibits was that by Mr. R. L. Mond, consisting of the apparatus intended for the Davy-Faraday Research Laboratory at the Royal Institution. Messrs. Siemens Bros. and Co. showed an historically interesting series of apparatus in connection with electric discharges in vacuum. One of these was a fac simile of Dr. William Watson's vacuum tube of 1751—the first apparatus ever constructed for experiments on the electric discharge in a vacuum. Prof. Dewar showed a variety of striking experiments with liquid air, including solid alcohol, frozen soap bubble, distilling mercury and phosphorus, the diamond burning in liquid oxygen, ignition by means of a lens of liquid air. The Lords of the Committee of Council on Education have arranged for the public exhibition in the western galleries of the Science Museum at South Kensington of a number of the objects shown at the soirée. The exhibition will remain open to the public for about a fortnight.

Theories of Magnetism.—One of the interesting points in connection with the recent investigations into the effects of very low temperatures on magnetic properties is the possibility of their throwing some light on what really takes place when iron is magnetised. In his discourse last Friday at the Royal Institution, Dr. Fleming stated that the decreased permeability of soft iron at the temperature of liquid air was explicable on the magnetic-molecule theory, since the cooling of the iron, with its consequent contraction, brought the molecules closer together, and their mutual attractions being thus increased it naturally required a greater magnetising force to collineate them. But the increased permeability of hard iron at the same temperature was more difficult to explain on any accepted theory of magnetism. It is to be presumed, however, that Dr. Fleming's difficulty lay mainly in making the matter intelligible to all his audience within the narrow limits of the minutes to spare at the end of a discourse. For assuming that in soft iron each molecular magnet is comparatively free to turn, the condition of hard iron will correspond to the formation of a quantity of highly stable groups of molecular magnets which have to be broken up in order to secure collineation. But when it is remembered that, though little enough is really known about molecules, the one thing certain about them is that they contain a good deal of motion, it is seen that the equilibrium must be one of a stable system of moving bodies. It is not difficult, therefore, to conceive that the subtraction of a large percentage of the molecular motion consequent on excessive cooling might seriously impair the stability of some of the groups, or, what is the same thing, increase the permeability. What, however, is really wanted for the theory in question is some explanation of how and why the iron molecule can act like a tiny permanent magnet.

From the Gasworks Point of View.—It is always wholesome to see ourselves as others see us, and therefore the presidential address of Mr. W. R. Chester delivered at the thirty-third annual general meeting of the Incorporated Gas Institute held on Tuesday at the rooms of the Society of Arts, Adelphi, is worth some few lines notice. Mr. Chester dwelt on the rivalry between the electric light and the gas industry, and urged that in the race for public favour the former was for many years to come likely to enjoy the equivocal complimentary title of "the light of the future," which no gas engineer would grudge it. The latest returns to the Board of Trade showed that £69,423,431 had been invested in the authorised gas undertakings of the country, which was an increase of £1,750,000 on the previous year. The coal carbonised had been 11,319,301 tons — an increase of 300,000 tons on the previous year. The gas sold had been 105,160,990,000 cubic feet, an increase of 3,274,000,000 cubic feet on the previous year ; while the total receipts amount to £19,408,265, and the cost of production to £13,791,520, thus leaving a margin of £5,616,745 gross profit, sufficient to pay 8·1 per cent. on the total capital employed. As to the electric light, it appeared that the total capital invested in the authorised undertakings of the country was £6,470,942, the output of electricity being 24,145,719 Board of Trade units, the receipts £692,734, and the expenditure to £377,691—leaving a balance of £315,043 as gross profit, which was equal to 4·87 per cent. on the capital employed. The total output of electricity for the whole country was little more than one-half the normal progressive increase in the consumption of gas for one year, or, to put it in another way, nearly two additional installations of electric light plant of equal magnitude to the existing ones would have to be put down each year before the normal annual growth in the consumption of gas would be arrested. All this no doubt sounds extremely comforting to the gas engineer. It is always a difficult piece of business to turn out people who are in possession of the field, and, apart from that point, it would have been very much more to the purpose if Mr. Chester had given us some statistics as to the profits and prices of gas companies in the years when gas lighting was yet a young industry.

The Fastnet Lighthouse.—In the fourth report of the Royal Commission on communication with lighthouses details are given of the method of communicating with the Fastnet lighthouse, which is situated about seven miles off the south-west corner of Ireland. The precipitous rock on which the lighthouse is built is exposed to the full force of the Atlantic seas, and is unapproachable except in calm weather. In 1885 electrical communication by a continuous cable was established with the lighthouse at the instance of the committee of Lloyds, who had received permission to use it as a signal station, but the difficulty and expense of maintaining the connection were so great that it was abandoned at the end of 18 months, after several lengthy interruptions in communication had occurred. Having regard to the difficulty of maintaining electrical communication with the Fastnet by means of a continuous cable, the Commissioners have now tried a non-

Digitized by Google

continuous system since July 18, 1895. A submarine cable of the ordinary type, 7·0288 knots in length, is laid from a small bay called Galley Cove, towards the lighthouse; the sea end is spliced to 17 fathoms of heavy copper wire, insulated with indiarubber and protected by lignum vitæ rings; and this wire terminates in a copper mushroom anchor weighing 4½cwt., which is submerged in 11 fathoms (low water) at a distance of about 60ft. from the Fastnet. The shore end is connected by a subterranean cable with the post office at Crookhaven, from which is laid another cable 200 yards long, terminating in a copper centipede anchor, sunk in about two fathoms of water in the haven on the further or north-east side of the promontory on which the post office stands. At the Fastnet two short copper conductors, connected with the instrument in the lighthouse, are bolted to the sides of the rock, one on the north, or land, side, and one on the south side, each terminating under water in a copper centipede anchor. This is the present arrangement, but one of the conductors having been broken by the action of the sea, it is proposed to protect the exposed parts of both conductors by passing them through holes which will be drilled in the rock for the purpose. The mushroom anchor near the rock and the centipede anchor in the haven form the earth plates of the line, the post office at Crookhaven with its batteries and instruments being intermediate. The circuit is completed by the sea, but part of the current passing through the circuit is picked up by the nearest copper conductor on the rock and actuates the telegraph instrument placed in the lighthouse. It then passes through the other copper conductor into the sea. In the reverse direction part of the current sent from the lighthouse is picked up by the mushroom anchor, and passing along the main cable, actuates the telegraph instrument in the post office at Crookhaven. The instruments used both at the lighthouse and at the post office are a double current speaking-key and a dead-beat d'Arsonval reflecting galvanometer, and the signals are those of the Morse code. Except for a short period when one of the conductors on the rock was broken, telegraphic communication has been maintained throughout the winter, but it has not been possible to apply the ordinary arrangement for calling attention by means of a bell, and it has therefore been necessary for the operators to go to the instruments at stated intervals to ascertain whether there was anything to communicate. Now that the winter has passed, and it has again become possible to work on the rock, no time is to be lost in fitting a call-bell, which will be worked by a specially devised relay.

Communication with Lighthouses.—Some time ago we gave the conclusions arrived at by the Royal Commissioners on electrical communication with lighthouses and light-vessels, which was to the effect that they could not yet make a final report, as though communication with lighthouses was fairly satisfactory, the serious difficulties which continue to be experienced in maintaining electrical communication with light-vessels on the system now employed necessitate further experiments being made in this direction. The Commissioners have, however, issued a fourth interim report, from which it appears that while at the time of the third report electrical communication had been established with four light-vessels, Goodwin (North Sand Head), Kentish Knock, Shipwash, and Hasborough, one pile lighthouse (Gunfleet), two lighthouses on small islands or isolated rocks (Lundy and Tuskar), and 38 shore lighthouses, to this list may now be added the Fastnet and Caldy lighthouses, the Formby light-vessel, Maplin pile lighthouse, and Bidston and Llanddwyn shore lighthouses. There are, therefore, at present five light-vessels, six island, pile, or rock lighthouses, and 40 shore lighthouses around the coasts of the United Kingdom which have been placed in electrical communication with the general telegraph system of the country at the national charge. The Mersey Docks and Harbour Board have also connected for their own purposes five of the lighthouses under their control, and one or two other shore lighthouses have been connected by similar bodies in the United Kingdom, apart from any recommendations from the Commissioners. Details are given as to the troubles experienced with the lightships, the interruptions experienced being apparently due to the impossibility of preventing the electric cable chafing against the mooring cables or the ship itself, and in one case at least there was a breakage due to the ship riding to the electric cable. The Commissioners therefore propose to experiment with a non-continuous system, under which the cable running from the shore is laid in a circle on the bottom of the sea immediately under the light-vessel, the circle having such an area that the vessel will always be within the circumference of it. Round the deck of the light-vessel a number of turns of insulated wire are coiled, which are in connection with a telephonic receiver on board the ship. An intermittent vibratory current is sent through the cable, and is made and interrupted by a Morse key. The vibrations act by induction on the coils of wire on the light-vessel and produce buzzing sounds in the telephone, which, being intermitted by the Morse key, are read as in the ordinary Morse code. By means of a special arrangement a call-bell can be rung. In the same way messages can be sent from the light-vessel to the shore. This system has not yet been subjected to a practical test at a lightship, but the Commissioners regard it as offering greater chances of success than any of the other inventions of the same nature, and meanwhile defer recommending the establishment of electrical communication with any further light stations, awaiting the result of the experiments which are about to be made. In an appendix details are given of what has been done in the Colonies and abroad. With the exception of Newfoundland it may be said that in the Colonies there is, in general, electrical communication to lighthouses on the mainland, but not to outlying lights or lightships, but in Queensland the half-dozen island lights are connected. In India there is hardly any communication. The practice of foreign countries differs widely. In Denmark, which the Commissioners visited, there is a very perfect system. In Germany, Holland, and Russia there is a good amount of connection, and in most other countries there is very little; in France none whatever, and the United States are still discussing the question, but have about half-a-dozen lights connected. None of these countries have any connection with lightships.

The Pacific Cable Conference.—The first meeting of the committee appointed to consider a scheme for establishing direct cable communication between England and Australia, *viâ* the Dominion of Canada, has been held at the Colonial Office. The Imperial delegates were Lord Selborne, Under Secretary of State for the Colonies, and Mr. G. H. Murray, C.B., a principal clerk at the Treasury; the Canadian Commissioners were Sir Donald Smith and Sir Mackenzie Bowell, with whom was Mr. Sandford Fleming, C.E., who is acting as their technical adviser; and the Australian representatives were Sir Saul Samuel and Mr. Duncan Gillies. The proceedings were private. The *Times* has devoted a column and a half to the subject. And after giving an account of the origin and progress of the inter-colonial cable scheme, the present state of things is summed up as follows: "Early in June of last year the agent of the (French) com

Digitized by Google

pany owning the cable from Queensland to New Caledonia entered into negotiations in Honolulu for landing privileges and for a subsidy for laying a cable from San Francisco to Honolulu. Not long afterwards orders were given for the manufacture of a cable to be laid between San Francisco and Honolulu, and in September it was known that the Hawaiian Government had concluded a contract under which a company could be formed for laying a cable from San Francisco to the Hawaiian Islands. The company will be subsidised and will have the exclusive right to lay cables within the Hawaiian Republic. The cable is to be begun not later than May, 1897, and to be completed in November of 1898. Under the contract no cable can be laid from Canada to the Hawaiian Islands for 20 years, thus forcing all Canadian business to pass through the United States, and barring the British groups of colonies from any cable connection *vid* the Hawaiian Islands except through the American company. The contract places the control of the company under the Government of the United States. Thus, as the position stands with regard to the construction of a Pacific cable under foreign control, it is provided that by the end of the year 1898 an American section from San Francisco to the Hawaiian Islands and a French section from Australia to New Caledonia will be in working order. The construction of the intervening portion between New Caledonia and Hawaii will presumably depend upon the rapidity with which the British scheme is now proceeded with. It is not probable that the increase of cable business between the northern and southern hemispheres on that side of the world will for some time to come justify the construction of two complete Pacific cables. From the commercial point of view it is therefore a question of which is to be first in the field. The predominance of British trade interests in those waters would appear to justify the desire of the British colonies to keep the cable connection under British control. It will be the business of the present cable conference to decide in what manner this result can most practically be achieved." Further on it is remarked that as time is of importance to the favourable conclusion of the undertaking, it is to be regretted that the representatives of the Australasian Colonies at the conference should find themselves under the necessity of very seriously delaying the proceedings by absenting themselves from England to attend the telegraphic conference at Budapest. This absence may last six weeks, and during the whole of the time the proceedings of the conference are in danger of being suspended. "At this period of the year a loss of six weeks may mean that no conclusion can be arrived at in time for proposals to be submitted during the present or approaching sessions of the Imperial and Colonial Parliaments. The delay may therefore entail the loss of a whole year, and Australia, to whom the communication to be established is of more importance than to any other of the joint partners in the undertaking, may hereafter be called upon to bear the blame of having at a critical moment impeded the initiation of an enterprise in which the Imperial Government and the Government of Canada had demonstrated their readiness to take part."

Institution of Mining Engineers.—The twenty-first general meeting of the members of the Federated Institution of Mining Engineers was held last week at the Institution of Civil Engineers, Great George-street, Westminster. At the opening meeting on 4th inst. the chair was occupied by the president, Mr. G. A. Mitchell, and there was a large attendance from all parts of the country. The President, in the course of his address, remarked that the history of mining told of a constant [gradual progress, and they must bear in mind the past and remember that as it had been, so it probably would be. Familiarity with electrical transmission of power would probably lead to many changes in the future, and, among others, to the more extensive use of coal-cutting machines. Coal cutting by machinery had not in this country been a great success in the past, notwithstanding periods of activity in the introduction of coal-cutters from time to time. By the use of coal-cutters many thin seams should become workable that had in the past been neglected. It was possible that in the future it might be to the opening up of thin seams, worked by coal-cutters, that they must look for the maintenance of outputs in some districts. With coal-cutters the output might be long maintained. The experience of the past should teach them to be very careful about prophesying the exhaustion of coalfields. Their trouble at the present moment was that both in Scotland and in England and Wales too much coal was being produced, and there was depression in the coal trade in consequence. It was unfortunate that trade was hampered so often by disputes between masters and men. Miners at the present day did not appear to realise in what an immensely better position they were than those who preceded them. Subsequently a paper was read by Mr. H. W. Ravenshaw, in which he dealt with certain precautions which he considered necessary in the use of electricity in coal mines, Although the use of electricity for lighting and the transmission of power in coal mines was becoming more general, and many of the plants had been running for some years, no serious accidents or explosions had within his experience been traced to its adoption. In some districts, where the seams were very fiery, colliery proprietors had refrained from using electricity. Some writers on the subject had inclined to the view that there was little or no risk of the ignition of gas by the spark caused by the rupture of a cable through which the current was flowing. That, however, remained to be proved, and it was much better to guard against a possible danger than to run the risk of losing even a single life. As a matter of fact, the risks were few and easily guarded against, and there was no reason why electric motors should not be used in the most fiery mines if proper precautions were taken in putting down a suitable plant and keeping it in an efficient state of repair. In the evening the annual dinner of the institution was held at the Holborn Restaurant. On Friday, early in the day, the members paid a visit to the works of the Electric Welding Company, Limited, Pimlico, and inspected the Thomson electric welding process. At noon the reading and discussion of papers was resumed at the Institution of Civil Engineers. Mr. Bryan Donkin contributed a communication upon "Powdered Coal for Firing Steam-Boilers by the Wegener and other Systems." Amongst the advantages of using powdered coal firing as compared with large coal, he stated to be the absence of smoke after the firebrick lining had become hot, continuous and automatic fuel supply, less dependence upon the stoker, more perfect combustion, more easy regulation of the exact quantity of air required and of steam generated, saving in cost of labour, economy of coal, no grate or grate-bars, no fire-doors, higher furnace temperatures, and increase of boiler efficiency from 15 to 25 per cent. Amongst the disadvantages were the cost of grinding the coal, which would vary according to the difference of locality and quantities ground, but might be taken from 9d. to 1s. a ton, and repairs to firebrick lining. Visits of inspection were afterwards paid to the Deptford station of the London Electric Supply Corporation and other works.

Digitized by Google

MUNICIPAL ELECTRICAL ASSOCIATION.

The first meeting of the convention of this association has been held in London during the present week. We gave a full programme of the meeting in our last issue. The first meeting, on Wednesday morning, held in the United Service Institution, was well attended, among those present being Sir Courtnay Boyle, Major Cardew, and representatives of all the large electrical manufacturing firms. The papers were read in abstract, and we give below these abstracts, followed by the discussion and replies of the gentlemen reading the papers. The president (Mr. Arthur Wright, of Brighton) took the chair at half-past 10 a.m.

Presidential Address.

Mr. ARTHUR WRIGHT read his presidential address as follows:

You have done me the great honour of asking me to preside at this our first annual convention, and I feel I cannot take up a portion of your time to better purpose than by proving the pressing want of some such association as we are now inaugurating to further and protect the interests of the municipal electricity undertakings, which in the very near future will probably exceed 80 in number, and represent a capital outlay amounting to £4,000,000 sterling. I therefore propose to show how exceedingly numerous are the questions that are being constantly met with in our special branch of electrical engineering, and why, in my opinion, none of the existing societies can really supply our want. I think you will share my regret that the very nature of our problems, and the particular standpoint from which we municipal men have to look at them, prevents us from deriving the great benefit of having among our regular members the numerous experienced managers and engineers of companies supplying electricity.

Although the objects of this association are generally and very tersely stated in the constitution, I may be allowed to amplify the wording there by stating that, in promoting the special interests of municipal electricity undertakings by bringing together, for the purpose of comparing experiences, the men responsible for their management, we hope to succeed in getting the representatives of the ratepayers to participate in our discussions, and to obtain their valuable co-operation and municipal experience in trying to solve our difficulties, so that our recorded conclusions may receive the greater consideration from the head governing bodies. For the purpose of classification, I will divide some of the problems that have already confronted the management of municipal electrical undertakings into three distinct groups—those relating to policy, to commercial, and to technical questions. Although it could be truly said that some of the questions of policy come within the sphere of one, if not more, of the older societies, and that many of our commercial and technical problems could be advantageously discussed from a general point of view before some of them, yet it must surely be to the advantage of the community to have the particular interests of our industry safeguarded and properly represented by an association comprising among its members the representatives of the ratepayers and the technical officers in charge.

The group of "Questions of Policy" must obviously include those relating to what should be the proper period allowed for the repayment of loans. That some decision ought soon to be arrived at is evident when we remember that in London the vestries can get permission from the County Council to repay their capital in periods exceeding 40 years, whereas in many of the provincial towns 25 years is the period fixed by the Local Government Board. There is obviously no reason why posterity outside the Metropolis should be so much more generously dealt with, at the expense of the present generation, or why folks in the provinces, who have to pay all the expenses and suffer from the inevitable troubles incidental to the starting of a new industry, should also have to behave so much more handsomely to people who it must be remembered will have an advantage over us in being born 25 years later in the world's progress. Take, again, the question of assessment of electricty works and mains. The interpretation of the law on this point is so uncertain among experts that it is actually possible, in the case of two municipal electrical undertakings in the South of England, for the relative assessments to be nearly as 10 is to 1, although the capital invested is about equal. At first sight, to anyone not directly interested in the success of municipal electricity works this variation of assessment would probably not be considered very serious, as apparently it is only a question of taking money out of one municipal pocket and putting it into the other; but to the men responsible for the success of this one special department the question of assessment affects the vital results of the electricity undertaking paying or the reverse, and increases or diminishes the near possibility of a reduction in the tariff for supply, which they realise is necessary to ensure the general use of electricity among all classes of ratepayers.

The decision arrived at as to what policy should be pursued in relation to the profits obtained, has a similar effect on the rapid growth of municipal electricity undertakings. The practice of insisting on maintaining high tariffs so as to be able to hand over large profits to the general body of ratepayers, on the ground that they should be handsomely repaid for their risk in mortgaging their rates, is very naturally resented by those ratepayers who make use of their own municipal supply. They contend that by this policy they are being severely taxed, in the shape of having to pay heavy electricity bills, for the benefit of a number of people who we now know ran practically no risk at all, and as non-users do not help their own municipal enterprise. Again, when we remember how prone some municipalities are to pride themselves on the large profits made in their undertakings, and when we remember the policies advocated by some of our friends who would lead us to imagine that the object is simply to supply electricity to those who can afford to pay the necessarily high initial price, it is evident that good must come from our discussing this point, and bringing home to the governing bodies the truth that the criterion of success of a municipal electricity undertaking, trading in what cannot be called a necessity, is not so much the profits made out of the undertaking as the more or less general use the ratepayers make of the supply offered.

Those who advocate putting aside a large proportion of the annual profits to building up a reserve fund for use in case of unlooked-for contingencies are often charged with want of consideration for the general ratepayers who backed the necessary cheque in starting the undertaking; these critics, however, forget that in this matter it is the duty of a corporation not only to start but to continue to supply a cheap and satisfactory service, and to insure against any possible mishaps that may arise in the future. Again, the question of creating a mutual electricity works insurance fund seems a fitting subject for discussion, considering how all our works are now being tarred with the same brush by the fire offices, and classed by them among the same hazardous risks as factories, etc. Again, the practice of the various municipalities differs considerably in deciding whether one or separate committees should manage the gas and the electricity departments. The former practice frequently prevails, and what seems to many of us the inevitably slow progress that results from such a policy is not at present fully realised. In some towns human nature seems to be so over-rated that their corporations have made one manager responsible for these two competitive departments.

Another point in connection with the general policy that is to be followed in carrying out municipal electricity undertakings is one on which electricity works managers are not by any means all agreed among themselves—namely, whether a corporation should make all ratepayers pay a uniform profit on the cost of production of the electricity they individually consume, or charge a uniform price to everybody. I scarcely need add that the two systems cannot both be adopted. The former has the advantage of justice on its side, while the latter has that of greater simplicity; unfortunately, however, it involves the commercially unsound principle of charging the same price for commodities which may individually require capital outlays differing as much as tenfold or more. Again, owing doubtless to the youth of our industry, no definite rule has

Digitized by Google

yet been established among municipalities as to how they should charge for electricity consumed in their street-lighting and public buildings; whether, for instance, this should be done on the sound principle of having only one universal tariff, or should special tariffs be arranged for their own municipal consumption. The latter course, in view of the charges that are constantly being made of some corporations making their electricity profits out of their own pockets, seems difficult to justify.

The wisdom, or the contrary, of municipalities taking joint action in threatened patent litigation, or in view of new parliamentary regulations or restrictions, wants discussion and settlement. The questions whether municipalities should carry out the wiring of private premises in competition with local tradesmen; whether they should have powers to hire out motors, arc lamps, and fittings; the advisability of establishing municipal telephone systems, electric fire-alarms, and electric fire-engines; the possible benefits of combining the water and electricity works; the use of the plant in periods of light load for the production of such by-products as disinfecting fluids, acetylene, and carborundum, etc., are all interesting problems of policy which, I trust, will be ventilated and argued at our conventions.

Another municipal variation of practice is shown by some believing that it is to the interest of the ratepayers to employ a sufficiently strong resident engineer to carry out both the design and the running of their undertaking, on the ground that no one but a resident can properly grasp and retain the local bearings of the problems involved in a distribution scheme of the nature of electricity supply, while others consider that a consulting engineer, owing to his having the opportunity of gaining much more varied experiences from all sorts and conditions of towns, would serve them in better stead. On the answer to the above delicate question of course depends what should be considered the proper remuneration of the resident engineers who have the virtual control, whether their councils fully realise it or not, of property amounting in many cases to hundreds of thousands of pounds. The touring experiences of many of our best electrical engineers is advantageous to the men themselves in gaining fresh experiences, but it increases the unfortunate loss to the corporations when the engineers are snapped up for better appointments elsewhere. The existence of this constant system of changing proves beyond all doubt that many corporations have not yet realised the value of the immense experience these men take away with them, and how impossible it is to replace their experience by even better men until some considerable time has elapsed. Some corporations fully see the advisability of getting their engineers to visit other electricity works for the purpose of keeping up to date. The great extent to which the ratepayers benefit by this policy is not, I am sorry to say, apparent to all the governing bodies.

Although many of our senior brother municipal officers will be prone to think that some of the above questions do not come at all within our province for discussion, I feel that if we obtain the valuable assistance of the chairmen of our committees in discussing and solving them there will be little difficulty in getting the correct principles accepted and adopted by our councillors. All the above, and a host besides, are questions of policy that press for solution, and I think many will agree with me in thinking that if we leave them to the other societies to fight out, we may as well adopt the equally slow course of leaving each corporation to worry for themselves when they are individually confronted with them. The founders of this association saw that co-operation in arriving at conclusions upon these problems would save a great deal of time. and would avoid the repetition of a vast amount of work by the different councils. They also saw the importance of putting in black and white the results of careful consideration by competent men of the different policies advocated, so as to afford help to those among their *confrères* who may be in need of it.

With the second class of problems connected with our work—viz., those requiring consideration from a commercial point of view—it seems to many of us quite impossible to get this class of question satisfactorily and adequately discussed before societies, however influential and well organised, which comprise among their members men representing absolutely conflicting interests, and it appears equally futile to discuss these questions before institutions including among the members the managers of electricity supply companies, whose object in developing their business—viz., to get the biggest return on the capital expended—is so entirely different to ours in trying to supply the greatest number of ratepayers at the smallest possible cost. Moreover, it can hardly be fair or interesting to the majority of the members of existing engineering institutions for us to take up their time discussing problems which can only properly be thrashed out before a special body representative of our particular subject of municipal electricity supply.

Under the heading of "Commercial Problems" must come the important question of the proper organisation of the electrical staff—that is to say, how to so organise a staff and separate the undertaking into separate departments as to be able to define the duties and responsibilities of each member of it, and to ensure against any discontinuity in the business in case of illness or resignation of the chief officers. Whether the principle of giving the staff a bonus depending on the results of the year's working is likely to be to the benefit of the ratepayers or not is a question on which much can be said on either side; and it ought not now to be difficult to decide what should be considered the proper scale of remuneration to the different members of the staff in accordance with their term of service, so as to avoid as much as possible the inconvenience and loss of experience to a corporation of having their officers merely use the undertaking as a sort of training school. I think a very useful purpose will be fulfilled by our association if we could all agree on some proper method of keeping electricity accounts, or, perhaps, I ought to say of properly filling in the Board of Trade regulation form of accounts.

Everyone will now admit the great value electric lighting statistics, financial as well as technical, would be providing they were made on an absolutely uniform basis, and I trust some of our members will early suggest some form which we can all approve and adhere to. The question as to the right method of determining the cost of electricity supply has yet to be thrashed out, as it seems to some of us that the usual method of taking the average cost of all the units delivered is as useless for the purpose of calculating the cost of supplying any one class of consumer as if a land agent were to calculate the cost of a particular plot of ground in a town by dividing the total land value of the town by its total area. On this matter of costs depends the very important question of the actual cost of electrically lighting streets; also whether there is any justification, commercial or otherwise, for the plan adopted in many towns of charging a lower rate for electricity consumed in motors than in lamps.

Another most interesting and still unsettled point is what should be the basis on which to calculate the cost of energy wasted in feeders, transformers, etc., for the purpose of determining the relative cost of different systems of distribution. I have not yet succeeded in meeting two men agreed as to how this should be done. Again, it has not yet been generally recognised, as some think it ought to be, that it pays a corporation to cater in our industry for the same class of people that proves so remunerative to the railway companies—viz., those who choose to travel third class—and that it would probably be very much more advisable for corporations to run mains in their districts than only into the districts occupied by the houses of the rich and often-absent residents or the early-closing shopkeepers. To put it shortly, many of us have still to realise and prove to our governing bodies that it may be far better to get electricity used in a poor man's kitchen and one dwelling-room than it does to get it into many of the drawing-rooms of the wealthy. Again, you will all agree, I feel sure, that it is very important, in order to inspire confidence among the ratepayers, to show as early as possible after the starting of a municipal electricity undertaking that it can be made self-supporting, and therefore independent of the rates. With this object in view it is an interesting problem in electricity supply to find whether capital is better employed in the early days of an under-

Digitized by Google

taking in extending its sphere of operations into all parts of a borough, or in spending money on coal-saving refinements. To point out a danger confronting many of us, I may add that sound business men often express a belief that electricity undertakings would progress much faster if their managers took as much interest in understanding the commercial problems as they do in the over-absorbing engineering details and the fascinating scientific points connected with the industry.

The subject of wiring regulations and fire risks is one that has already received a great deal of attention, and I submit that it is still an unsettled question whether we are not weakening our position by enacting pages and pages of regulations which we have no very practical means of enforcing, and cannot afford to keep a sufficient number of inspectors to see carried out. Although I believe a certain amount of regulation writing is necessary in the early days of any industry, yet, in view of the utter absence of observed regulations concerning the use of paraffin lamps and compo gas-pipes, one may be forgiven for thinking that it is better to realise at once the futility of electricity supply authorities formulating regulations; that the proper people to do this and see them carried out are the fire offices; and that the more thoroughly this is recognised, the more likely these offices will be to fall into line and organise their staffs so as to ensure strict and general inspections. This seems to me to be the only way to improve the character of the interior wiring work, which at present varies much in quality.

With regard to the last group of questions, those of technical interest, which to most of us are infinitely more attractive than those of commercial expediency, it is hardly necessary for me to do more than enumerate many of the most pressing problems. Foremost among these, in my opinion, must surely stand the question of what should be considered the best system of distribution of electricity to any particular town or district. That the present state of things cannot be finality is obvious when we bear in mind how numerous are the different methods at present advocated and in use for towns of comparatively the same class. Owing to the absence of some such association as ours, this vital question has not yet been thrashed out by men who are unconnected financially with particular systems, but I hope we shall not be so very much longer now in settling upon some method of selecting the plant and means of distribution which should be put down by a municipality, so as to ensure an absolute continuity of cheap electricity supply, and at the same time bear the severe practical test of enabling the manager and the rest of the officers who have to work during the day to go home comfortably to their 5 o'clock tea without expecting every moment to be rung up on account of some mishap or other. In connection with this battle of the systems must be decided the proper voltage of supply to be adopted by works to be erected in the future, also whether it is advisable, and, if so, in what state of their progress, for works in actual operation to raise their voltage of supply, and the best method of effecting the change. I only wish I could see a chance of our discussing within the next year or so such specially interesting technical problems as the advisability of earthing the neutral conductor of a low-tension system of supply, the most suitable class of mains to adopt, the proper size of feeders and generating units, the advisability of adopting for commercial, if not technical, reasons one uniform periodicity for alternating-current plant, the wisdom of interconnecting all the low-tension network of a town, etc.

Although the question of the best design for an electricity works depends so much on local circumstances, yet the main considerations affecting this ought now to be determined. The question of locating faults on a system of distribution is another point on which we must all derive benefit by comparing our different methods and difficulties. Up to the present busy men in practice have been apt to keep their various methods too much to themselves, forgetting that probably the combination of other methods with their own would be of great value. As it has now been recognised that the present system of wood casing for interior wiring cannot be considered finality either from an electrical or æsthetic point of view, a paper on this subject up to date would be most interesting and useful to all of us. Again, the best means for lighting streets, wide and narrow, can now, with the experience of many of our members, be advantageously discussed.

Our constitution has been framed on a very liberal basis, and I trust we shall escape the internal troubles which some of the older societies have had. On Friday we proceed to elect from among our members a president, two vice-presidents, three members of committee, a treasurer, and a secretary.

In conclusion, I feel sure that if we can only persuade ourselves to be mutually communicative and ready to exchange our views and experiences, the result will be so beneficial to the community at large that they will be as thankful to the members who first took up the idea of forming this association as we ourselves ought to be to Mr. Madgen, our first very energetic hon. secretary, who by his ability in organisation has done so much towards making this association promise to be a permanent and useful success.

Mr. A. S. BARNARD, M.I.E.E., A.M.I.C.E., borough electrical engineer, Hull, read a brief abstract of a paper he had prepared on

Electricity Supply at 220 Volts.

The author dealt chiefly with the advantages and disadvantages of the use of 220 volts on the distributing mains, and thought it was probable that many engineers whose stations were at present working at 100 to 110 volts would gradually persuade their customers to take a supply of 200 to 220 volts, which would at any rate be an immense gain to the supply works. He considered that in the majority of cases the change likely to be made would be the doubling of the pressure throughout. The advantages of the changes were, briefly, as follows: (1) existing mains can supply twice as many customers, at the same time reducing the percentage of loss in the cables by one-half; (2) variations and fluctuations due to the switching on or off of motors or large groups of lamps, or carelessness in switching dynamos in or out at the station, are all reduced by at least one-half; (3) new customers can be supplied at a much greater distance from the station. After considering the effect the change would have on present systems, the author proceeded to explain how it would affect the wiring and fittings on consumers' premises. As far as present experience went, there was little, if any, increased danger of fire by adopting 220 volts. In regard to the neces sity of a higher-efficiency lamp, he adduced evidence to show that 220-volt lamps could be obtained which compared very favourably with the 110-volt lamp.

Alternating-Current Stations and High-Voltage Lamps.

This was the title of the paper written by Mr. H. W. COUZENS, borough electrical engineer, Taunton, and in alluding to the principal points contained in it, he said it was originally intended for a magazine note on the subject it dwelt with, and that accounted for some of the prefatory remarks, which might otherwise seem to be unnecessary. His object through the paper was to bring before the notice of the association some of the cases in which high-voltage lamps would prove of service to the alternating engineer. In the first place, it would lead to the extension of the sub-station system of distribution to scattered residential districts to take the place of distributed transformers; and, secondly, the substitution of increased pressure in these places would be a comparatively simple matter. Alternating-current engineers had been slower to take up this question as it had not been forced so necessitously upon them. He had every reason to believe that the advantages of increased pressure and reliability of lamps would make themselves felt in the near future.

DISCUSSION.

Mr. R. C. Jackson, the engineer of the Newcastle-on-Tyne Electric Supply Company, said that he thought too much attention had been paid to the saving in mains when 200-volt lamps were used. The more important point, in the consumers' interest especially, was that of the efficiency of the lamps. He thought no

Digitized by Google

one would dispute the fact that 100-volt lamps were more efficient than 200-volt lamps, even as 50 volt lamps were better in this respect than 100-volt ones. He thought the time was coming when the fight between the gas interests and electric light would be even more keen than at present, and the use of small candle-power lamps would be of great service in this struggle. High-voltage lamps were not so economical as those now in use, and he doubted if lamps of 4 c.p. and 5 c.p. could be made to work at 250 volts. This point he considered more important than the saving in mains. He finally would suggest that the association would do well to take up the question of the relative values of different types of lamps for different voltages and decide definitely on their respective efficiencies and life.

Mr. V. A. H. McCowen, of Belfast, considered that the great feature in the 200-volt system of distribution was that of the increased capacity of the mains. If the Westinghouse Company's application for the extension of time for Dr. John Hopkinson's three-wire patent was granted the higher-voltage lamps would be of great value, as with them heavy royalties could be saved. He considered that Mr. Barnard in fixing the limiting area of supply with the 110-volt three-wire system at the square mile had fixed it too low. This limit could be raised considerably.

Mr. J. H. Rider, of Bolton, said it was amusing to see how the "low-pressure men" had been compelled to rush on the high-pressure work with 220-volt lamps on their mains. The supporters of the low-tension system had always said that the high-tension system was an essential one for incandescent lamps, and that arc lamps supplied by it were bad. Now the low-tension gentlemen were prepared to give up single arc lamp or two in series and small motors, and to adopt a system by which four arc lamps were the least possible number in one place unless one consumer cared to have, say, two lamps in series with two lamps in the next consumer's premises, with the objection that his light could be turned out by his neighbour. To the alternating system this 200-volt lamp was in these days of low-tension mains equally useful as the low-tension system, and at the same time by means of a transformer one, two, or any number of arc lamps could be supplied. He considered that the alternating system had none of the disadvantages of the inflexible supply of direct currents at high voltages.

Mr. C. H. Wordingham, of Manchester, said that the works in that city had given the lead in this matter of high-voltage supply, as they had a five-wire system with 400 voltage across the outer wires in working order before anyone else had attempted it. Their success showed the Board of Trade that the higher voltage was safe, and helped, he thought, in obtaining the permission to use 200-volt three-wire systems elsewhere. He had not had much experience of 200-volt wiring, as most of the consumers were supplied at 100 volts, but he would warn those present not to accept the statement that ordinary fittings could be used. He had experimented with some of these, and then showed the charred remains of some porcelain fuses which had failed to break a 200-volt circuit. The fuses had been supplied with three ampere fuse wire, and then a current equivalent to 50 amperes turned on. These fuses would break the circuit, however, if the porcelain covers were not on. He thought the 200-volt lamp had not yet killed the five-wire system, and that the difficulty of using single arc lamps, etc., referred to by Mr. Rider could be got over as follows: in those districts where small shopkeepers were likely to want arc lamps, two additional mains could be run, and two balancing transformers used. This would practically make a five-wire system. As regards Mr. Rider's remarks on the alternate-current supply at different voltages, he did not see why electric lighting undertakers should be obliged to give an infinite number of pressures to the various consumers. This would lead to a large number of different transformers being required, which he thought inadvisable. He did not agree with Mr. Barnard's statement that the 220-volt supply would reduce the cost of starting resistances for motors, as although the current was halved the voltage to be observed by the resistance was doubled.

Mr. C. H. Stearn, of the Zürich Incandescent Lamp Company, considered that it was a fortunate augury that the Municipal Electric Association had placed this high-voltage lamp question in the foreground of their first meeting. He believed that the opposition to the use of these lamps would die away. As regarded the fittings to be used ordinary care must be taken in their selection and although a few short-circuits might occur, he did not think they would be more numerous than with 100-volt pressure. He did not agree with a previous speaker that the efficiency of an incandescent lamp increased as the voltage decreased. A diminution of the section of the filament did not affect the efficiency unless the mechanical strength of the filament was prejudiced. A perfect filament of only two mils diameter could be made equally efficient with any filament to work at 50 volts, and mechanical support could be given to those thin filaments if required. He did not think that high-efficiency lamps were in general use, and considered that the average lamp as now sold required from 3·7 to 4 watts per candle, whereas 230-volt lamps, requiring only 3·5 watts per candle, could be easily obtained. He would recommend that the engineers should be content with a somewhat lower efficiency at first, as those efficiencies had satisfied them at lower voltage.

Mr. H. Gibbings, of Bradford, did not consider the time was ripe for a final decision in these matters. They had used the high-voltage lamps successfully at Bradford, and had found that 3·7 to 3·8 watts per candle was the maximum consumption required. We should be able to decide the matter better in a year's time. At Bradford they had supplied some 380 customers at 230 volts during the past six months without complaint. He did not think that the low candle-power lamps were in demand, as the following figures of lamps now connected to his mains would show: 180 8 c.p., 10,491 16 c.p., 131 25 c.p., 1,084 32 c.p., 166 50 c.p., 120 100 c.p., 3 150 c.p., 5 250 c.p., 12 300 c.p.

Mr. J. E. Stewart, of Derby, thought that trouble might be found in changing an installation over to the other.

Mr. W. Arnot, of Glasgow, said that he had no doubt but that the different objections now found to supplying at the higher voltage would be overcome, and that the 200-volt lamp would be as safe and as efficient as the 100-volt. He referred to a conversation with Mr. Swan some years ago, when the speaker was assured that a 70-watt 16-c.p. lamp would be practical. Everyone knew how much this efficiency had been exceeded, and Mr. Arnot did not doubt but that the high-voltage lamps would be similarly improved. He also thought that the manufacturers would have no difficulty in providing switches, fuses, etc., to withstand the higher pressure. He personally believed in grouping such apparatus as much as possible. He said that the questions raised between high and low tension had been much exaggerated, as both systems had their advantages in different places. The real question in issue was rather whether direct or alternate current systems should be used.

Sir Courtenay Boyle said he was extremely grateful to them for having given him an opportunity of listening to what he considered a most practical and useful discussion. He was astonished at the exceedingly valuable character which had distinguished the remarks which had fallen from the various speakers. He was quite certain that such discussions as were carried on by their association must be useful, not only to the municipalities and not only to the Government and the particular department which he served, but also would be of advantage to that individual whom he had heard referred to in terms of unusual respect—he meant the consumer. Because, after all, they were all of them working in the interests of the consumer—he did not mean to say that the interests of the producer were to be disregarded; on the contrary, they were to be carefully safeguarded, but they were all of them working in the interests of the consumer, and it was to the consumer that they must look for the approval of their action. He had heard the presidential address and the discussion on the papers which had been read, and he only wished his engagements would permit him to stay longer. He was convinced that they who were dealing with the science which was still a young science had much to learn by discussion with each other. He was quite certain—he had heard speakers use language to fortify his opinion on this point—that hereafter we should know more than we do now upon the various points which had come up that day. He was somewhat appalled by the speech of the worthy alderman from Bedford when he said that the regulations of the Board of Trade were still in many respects very defective, and that there were several points which had not been dealt with. He could only say that if they would advise the Board of Trade to deal with them, they would act on that advice. The president, in his address, alluded to one or two subjects which might occupy the attention of the members of the association, and they were essential subjects, and which must be discussed by a body like theirs, but there was one suggestion which he might make, and that was: could anybody find out a name for a Board of Trade unit, which was now expressed in an extremely incongruous and lengthy term. It might be of interest to know that a short time ago he nearly succeeded in getting it called a Kelvin. If it had been, he was sure it would have met with general approval, but Lord Kelvin said he was connected with a supply meter which he was about to bring out, and that therefore it would not be proper to connect his name with a Board of Trade unit. There was another point which was still more important. He thought they at the Board of Trade must look to the municipal electrical engineers who were interested in the localities to guide them as to the behaviour of supply meters. As they knew, the duty devolved upon the Board of Trade to approve the pattern of a supply meter. Up to the present they had had considerable difficulty in discharging this duty, but he hoped some of the difficulties had now been overcome, and that they would be able to do something in that direction, but they must look to the local bodies to tell them how these meters worked in practice. Major Cardew could do it in a laboratory, but that was a work in which he thought a body such as that might offer very useful and very valuable assistance. But all the duties beyond it were sure to be well done, if he might judge from what he had heard that day. He offered them his hearty congratulations, and urged them to continue the work they had so well undertaken. If any assistance could be given to their discussions by the department which he served, it should be heartily at their disposal.

Reply to the Discussion.

Mr. Barnard, in replying to the discussion, dealt first with Mr. Rider's remarks, and said the points which he had depended on were small candle-power lamps, the use of single arc lamps, and the inflexibility of the 220-volt system generally. He thought the system could not be quite inflexible when it was so easily altered in central streets or central districts by the five-wire system by means of the motor transformers. This had been done in Bradford, and it was what he proposed doing in Hull in one particular district. It got over the objection of their being unable to supply 100 or 50 volts for a single lamp of the power of arc lamps. With regard to small candle-power lamps, Mr. Gibbings said they had a proportion of only 180. He believed that in Hull theirs was a smaller proportion than that. He did not think they should have 2½ watts for an 8-c.p lamp, and he did not think the consumers desired it. With regard to fire risks, Mr. Wordingham certainly managed to get a fine show of broken fuses, but he had succeeded

Digitized by Google

in making as big a result with finer fuses. (**Mr. Wordingham**: I congratulate you.) He thought they would find that they could rely on the makers to give them fuses, with very little alterations, that would answer for 200 volts.

Mr. Cousens said one predominant question seemed to be that of lamp efficiency raised by Mr. Jackson. He believed Mr. Jackson was engineer to a supply company, and probably the company supplied lamps to the consumers, but that, he believed, was not the general practice among corporations. They left the consumers to get their own lamps, and the consequence was that the consumer preferred a lamp that would last a long time to a lamp with a short life and a merry one. The consumer found a 3½-watt lamp the best, and that was precisely what he would get if he had a 200-volt instead of a 100-volt.

Municipal Control of Wiring.

The next paper to be discussed was that of Mr. C. H. Wordingham, city electrical engineer, Manchester, on "The Control by Municipal Authorities of Consuming Devices, and the Wiring connecting them to the Mains." Mr. Wordingham gave a short abstract, in which he pointed out that much doubt existed as to what power municipal authorities had for making regulations for the control of wiring, and although it was greatly to be desired that the Board of Trade should assist municipalities he showed that there did not appear to be much prospect of this being done. The authority given by provisional orders was found not be sufficiently definite for the purpose, and other orders must be obtained. Having mentioned the course adopted by the Glasgow Corporation, he said, although that was good, something more was wanted, and advocated the appointment of the municipal electrical engineer as a kind of consulting engineer. He also advocated a fee being charged. This fee would be small in the case of a very small consumer, and, of course, larger for a larger consumer. Among advantages which would accrue from such a course he enumerated that of the security to a consumer in being able to obtain impartial and good advice, and of having his work done under proper supervision, instead of the consumer being left to the interested advice of contractors. He felt this was a better alternative to the corporation carrying out the wiring themselves, which course would be far more likely to cause friction. The author proceeded to suggest the various headings under which these rules might usefully be framed, and the paper concluded with two suggested resolutions to be proposed for adoption at the convention for the carrying out of this object. The resolutions were as follows:

Resolved—That this convention of the Municipal Electrical Association is of opinion that the need of a standard set of regulations for controlling the fixing and connecting of consuming devices supplied from municipal electric supply stations is urgent, and that such regulations should be drawn up and adopted by members of this association.

Resolved—That a sub-committee of members of this association be formed to draw up a draft set of regulations, and to enquire what powers exist for enforcing such regulations when made, and also to ascertain how further powers for this purpose may be obtained if necessary; the sub-committee to have power to confer with any person or body of persons having special knowledge of or interest in the matter, and, subject to the approval of the council of this association, to obtain legal advice on the matter. The sub-committee to present a full report of the work to the next convention.

Discussion.

Mr. Lister Taylor, on behalf of a fire insurance company, said that at Liverpool he had found the installation work done by the local supply company most satisfactory. In fact, where he knew the company had done the work his duties in inspecting would be considerably lightened. He believed that Mr. Wordingham's proposals would work well, but he and Mr. Wordingham could not agree on the meaning of the proposals in the paper. In small installations, the speaker said that the cost of inspection was more than the premium obtained, and he seemed to think that it was safer to take the risk without inspection in these cases.

Mr. R. Hammond congratulated the association on the good attendance and success of their first gathering. The subject before them was a most important one. He had had experience of bad contractors, and had found it necessary to refuse two or three installations in each town to prevent the use of bad work. He did not consider Mr. Wordingham's proposal likely to injure the consulting engineer, as anything tending to raise the standard of work meant, in the long run, work for the expert engineer.

Mr. Chamen was to speak on behalf of the contractors, but said he could not claim to represent the wiring contractors, and certainly hoped he would not be taken to represent the bad contractors referred to. He believed in a code of good rules being enforced, but did not think the corporations should take up wiring work themselves.

Mr. J. S Raworth said that that was the only subject before the meeting in which he could claim to have no personal interest. He thought the tendency was to err on the careful side, as it took great premeditation to cause danger with an electric light installation. He considered that the worst installation of electric light was far and away better as regards safety than the very best gas installation. In fact, a previous speaker had stated the fire offices' views of the case to be that with small installations it was best to take the fees and not to bother with an inspection, as there was no need. He did not believe that any rules empowering a central-station official to enter an Englishman's house could be enforced. The consumer would prefer to go back to the gas and be blown up.

Mr. E. Manville believed in getting the general opinion of all the engineers, and then adopting one good all-round set of rules, rather than having several individuals each drawing up his own. He believed that it was hardly advisable for the corporations to do wiring work, but the penny-in-the-slot system with gas had necessitated a similar course with the gas undertakings.

Mr. W. Arnot, of Glasgow, said that all industries had suffered in the same way, and he had seen some gasfitting work in Glasgow disgracefully done. He was adverse to making the corporation responsible, as the public then would expect to be compensated for all defects in installations passed by the corporation officials. He quoted an amusing case where a man in Glasgow walked over a barricade as high as his chest and claimed £5 damages. He thought the officials had at present sufficient responsibility without taking up this new department, and also pointed out that the Continental practice was worse than that in England.

Mr H. Talbot, of Nottingham, believed in having rules and enforcing them. He had found by refusing to pass one or two installations that he could keep up the character of the work.

Mr. Panton, representing the Electric Light Committee of Bolton, thought if the corporation did the work themselves it would give the consumer a guarantee. He enquired if there was more than one town in which installation work was done by the corporation.

Alderman Carey, of Cardiff, supported these views, and **Alderman Higginbottom**, of Manchester, opposed them, and said he preferred the "authorised workman" system in use in Manchester.

Mr. Faraday Proctor, of Bristol, said that the corporation had not legal power to enforce the regulations. He had made a rule that if the installation did not come up to the required standard a charge of half a guinea should be made for the second test. He had imposed this charge some 50 times in the last few years and found the contractor preferred to pay rather than lose his credit.

Mr. J. E. Stewart, of Derby, had found that the fire offices often wrote asking particulars of installations he had passed, and he thought in future of charging 10s. 6d. for information so given.

Alderman Talbot, of Huddersfield, raised a most important point. If the corporation had the monopoly of the wiring, the increase of consumers due to the personal influence of rival contractors would cease. He considered that much of the success of central stations was due to the energy of the wiring contractor.

Mr. Albion T. Snell thought that the inspection of the work in progress by a consulting engineer was more likely to give satisfactory results than one inspection when the work was completed. He thought the consulting engineer would lose largely by the change proposed by Mr. Wordingham.

Mr. T. P. Wilmshurst, of Halifax, thought that they had power to make regulations, as Section 6 of the Act empowered them to make by-laws. The town clerk and himself were busy drawing up such laws, as their authority had been set at defiance by a contractor in Halifax who was also a tobacconist.

Major Cardew said, before speaking to the paper, he must be allowed to congratulate them on the extremely satisfactory attendance and the prosperous appearance of this convention. It was very satisfactory to the Board of Trade to see that that association had shown their confidence as usual in the Board of Trade by coming next door! As regards the paper, he would have thought from his experience that they would almost have had enough of regulations; it was quite a new feature to find them so satisfied with the regulations that had been made that they proposed to add a few of their own. That spoke well for the way in which the regulations were working out. There seemed to be a doubt first of all whether, assuming that it was desirable to make regulations, they would have any power to enforce them. He did not speak as a lawyer, nor did he attempt to interpret Acts of Parliament, but it seemed that somebody had discovered that there was a power of making by-laws. That was in the first Electric Lighting Act, but the power to make those by-laws was subject to the approval of the Board of Trade. These by-laws were to be for regulations for the protection of the public safety, but then how far that would enable municipalities to make wiring regulations was very doubtful. Wiring regulations were bound to be more or less dictatorial. They were to do this, or they were not to do that, and not merely to enunciate principles. So long as they could enunciate and enforce principles he thought that would be satisfactory to all parties, but the tendency was rather for the corporation electrical engineer—of course he would not have fads, but to have his own ideas as to how a house ought to be wired, and these ideas might be more or less expressed in the by-laws. Then, of course, first of all, it would be for the Board of Trade to consider whether such regulations should be approved or not. It

Digitized by Google

would be most injudicious to say now how they would consider anything of that sort until a case had been submitted to them, but obviously it would be undesirable to tie up the freedom of the consumer any more than it was absolutely necessary to secure the result which they wanted—that was to say, safety for himself and avoidance of interference with the safety of others. At the meeting of the Board of Trade when they last discussed the issue of regulations they were rather pressed to make the regulations dealing with house installations more stringent than they had been, and they did move in that direction as far as they could while still preserving to the consumer a sufficient amount of freedom, as was obviously indicated in the eighteenth section of the Electric Lighting Act of 1882, in which there was a clause on wiring which debarred the undertakers from enforcing any particular kind of lamp, etc., on the consumer. That clause clearly indicated a certain fear on the part of Parliament when this Act was settled lest the undertaker should assume too much power over the consumers, and thus perhaps to some extent to deprive the consumer of the benefit of the new systems, and perhaps to leave him at the mercy of one particular view as to how electricity might be supplied, which might not be satisfactory. To sum up this question of by-laws, he should say it was desirable in many cases that by-laws should be made. The Act gave the power and enunciated the purposes for which these by-laws should be made, and therefore in any case, whether the corporation found it necessary or desirable, on the ground of public safety, to add to the regulations of the Board of Trade generally, he thought it was advisable that they should make those by-laws, but that they should be of as general a nature and as far as possible enunciate the true principles and avoid particularising as to the particular kind of wires. As regards inspection, he should say certainly that they were not only entitled, but that the Act suggested that they should inspect before any connection was made. It seemed to him that it was intended that they should by the expression in the Act, "reasonable satisfaction," make some sort of inspection, and that any consumer who refused such permission would have only himself to thank if they refused to supply him. The general feeling was that an "Englishman's house is his castle." It was difficult in some cases, and it was not quite satisfactory to inspect after all the work was covered in; therefore, where they had early enough intimation—where the application had been made before the wiring was carried out, it seemed to him very reasonable that the engineer should call round and see the work while it was in progress, and just have his eye on it. No consumer with any sense would object to such an inspection. He concluded by again expressing his pleasure at being able to attend that day.

REPLY TO THE DISCUSSION.

Mr. Wordingham, in replying on the discussion, said a great many points had arisen on his paper, and it was very difficult to adequately reply to all the speakers. He was sure he was expressing the feeling of the meeting and of the whole association in saying how gratified they felt at having Sir Courtenay Boyle and Major Cardew with them that day, and it was most gratifying to have heard their speeches. As regards Major Cardew's remarks, they quite appreciated the difficulty of a corporation interfering too much in any consumer's premises, and also insisting on very minute details as to the system of wiring to be adopted, and that was why he brought forward his suggestion that the borough electrical engineer should be allowed to advise on these points. He would then be more in a position of a consulting engineer, but the work would be more personal than municipal. There would not be the irritating feeling of the corporation interfering. His idea was not to shut out the consulting engineers, but to have one man for every installation however small. A small fee should be paid for a small installation and a larger fee for a larger installation As to Mr. Snell's remarks about the consulting engineer personally inspecting all the work, he could not believe that a good consulting engineer could possibly personally look after every detail. He must have assistance, and so would the corporation engineer require competent assistance to go thoroughly into every question. His experience was that consulting engineers did not hanker after those wiring instal lations. It was most satisfactory to have Major Cardew's opinion as to their right to draw up certain by-laws and to inspect. He thought it was quite clear they were required to inspect, and the association might draw up a model set of by-laws, which should be on the lines Major Cardew had suggested. The Act was right in precluding the corporation from forcing any particular lamp on the consumer. Once the corporation had found a fault in a house, there their responsibility ended. With regard to the installation test, he thought that was absolutely misleading, more particularly in the case of a new building. As to the liability of corporations interfering too much with the wiring, that was his reason for proposing that they should be a distinct body through their engineers. As regards landlords and fittings, he found in Manchester that the landlord always did the wiring, and no doubt he charged it to the tenant. The uncon trolled contractor was very apt to put in twice as much light as was wanted in order to make plenty of work but that was very much to be deprecated. He did not oppose 200-volt lamps; he advocated them, but he felt that great care must be exercised in putting in the fittings for that pressure.

An adjournment was here made for lunch: after which a visit was made to inspect the Deptford station of the London Electric Supply Corporation, Limited.

THURSDAY.

The proceedings were resumed at quarter past ten, the chair being again taken by the president, Mr. Arthur Wright.

Letters of Regret.

The SECRETARY read letters from Lord Kelvin, Prof. Kennedy, and Mr. Kapp expressing their regret at not being able to be present at the convention, and congratulating the association on inauguration; and also letters from Mr. A. W. Heaviside (Newcastle) and Mr. George Wilkinson.

Cost of Electricity Supply.

The PRESIDENT then read a brief extract of his paper on "Cost of Electricity Supply." He pointed out that at present no very definite basis had been decided upon by which to calculate the cost of electricity supply, and illustrated the uncertainty on this question by the fact of so many different tariffs being still in existence. He discussed the usual methods of averages and that of Dr. Hopkinson, and as no one had hitherto published the results of applying the latter to actual figures, he proceeded to do so with those of the Brighton undertaking for the year 1895, using two methods, which he submitted were based on Dr. Hopkinson's method. In analysing the accounts he pointed out what he considered should be taken as constituting the cost of supplying electricity, and how the different items could be divided into the two classes of running and standing-by costs. He showed how a curve of total monthly expenditures could be analysed and fairly represented by an empirical formula. He then called attention to an obvious corollary of the ascertained low cost of continuing to supply electricity compared with the heavy charges for getting ready to do so, and that there was a greater necessity for differential tariffs in towns where coal was cheap than where it was dear. He then discussed how each consumer's proper proportion of the standing charges should be apportioned, and gave the method adopted by the Brighton Corporation in ascertaining this. Having agreed on a basis on which to estimate the cost of supply to any one consumer, he then pointed out that it was possible to make a profit and loss account for each year showing those consumers who proved profitable and the reverse. He then recorded some important conclusions which followed from this analysis of electricity costs, among the most important being that he considered that it was the duty of a municipality to charge on a system of uniform rate of profit than a uniform price. He stated that the extremely low price at which electricity could be supplied on the former basis more than compensated for its comparative complication. He urged the advisability of maintaining the initial price at the highest possible figure until the standing charges were covered, and then the reduction to as low a figure as was compatible with a small safe annual profit. He also stated, in his opinion, that it was erroneous to suppose that the cost of supplying short-time consumers, such as offices, etc., would very much diminish as the business increased, as the cost of this class depended almost entirely on the standing charges, and not on the running costs. As an illustration of the effect of these standing charges, he pointed out that it cost 2½ times as much to supply a unit to a consumer who used his light on the average one hour per day as it did to another who used it three hours. It was far easier, in his opinion, to reduce the average cost of producing electricity by improving the load factor than attempting to make the same reduction by economising coal. It was also the small householder and his shopping districts which afforded a more promising field for electricity supply than the residential quarters of the rich, and he pointed out that one of the most important corollaries from this theory of the cost of electricity was that streets could be lighted by electricity cheaper than by any other form of illuminant of the same candle-power, and probably the cost per unit for supplying this class of consumer and basements would not much exceed 1½d.

DISCUSSION.

Mr. H. Mavor said he agreed with Mr. Wright's paper, and strongly supported the differential rate of charge. He had devised

Digitized by Google

a method with which, although simple, he was not entirely satisfied. He took the total units used per annum and divided them by the total number of lamps installed. This gave the average hours each lamp was used. The charges were then varied by giving the following discounts: lamps used 1,000 hours, 10 per cent.; lamps used 2,000 hours, 20 per cent.; lamps used 3,000 hours, 50 per cent. With this system, profit could be shown when the charge came under 3d. per unit. As regards street-lighting, he thought that arc lamps could not compare with gas as to cost, whereas incandescent light could so compete. Still, it must be borne in mind that a gas plant to supply streets only would not pay at present prices.

Mr. H. M. Sayers, of Bournemouth, said he had adopted the Wright system of maximum-demand indicator, and found by it that the total value of the energy supplied had increased in spite of the reduction of the rate to good consumers. He did not believe Mr. Mavor's system to be at all feasible, as it tended to prevent the complete wiring of premises. At Bournemouth he found the cost of supplying an extra unit to be $\frac{4}{10}$d., including all standing charges. Again, at Bournemouth the maximum demand in 1894 was 168 amperes at 2,000 volts, while in 1895 it was only 163 amperes, although the units supplied had increased 18 per cent. Some 40 consumers who got substantial credit notes had taken 24·6 per cent. more units.

Mr. Alexander Siemens said the differential rate was most satisfactory and fair to the consumer. He regretted that he had not had time to read the paper thoroughly. In his own house he had installed the light everywhere, and had to pay 8d. per unit. The price of gas previously used had been 3s. per thousand, and he had found that the bills for gas and electric light fairly compared, and with all accessory illuminants added did not vary appreciably—in fact, the bill for electric light was slightly under that of gas. He did not see how wall plugs would be reckoned on the Mavor system. The great feature in a private house tending to keep the electric light bill down was that of having the switches placed handy so that the light could be switched off as one leaves the room.

Mr. A Ellis, of Bolton, said he had introduced a maximum demand system at Southport which had been most successful. He charged 7d. per unit for the first two hours' supply, and 4d. per unit afterwards. It had answered so well that now they charged all units after one hour's supply at 4d. The result had been an increase of 18 per cent. in the revenue.

Mr. C. H. Wordingham, of Manchester, claimed that the practice of charging a differential rate was first introduced at Manchester. They made a fixed charge per lamp per annum, and then charged the supply at 2d. per unit. This, however, discouraged the complete wiring of premises. He did not agree with Mr. Wright that all wages should be reckoned as standing charges.

Mr. Dawbarn believed that the load-factor was a most important point in the determination of fair charge. He thought there should be a unit for this quantity called the "Wright."

Mr. W. Geipel laid great stress on the importance of keeping the first cost low, and pointed out that if the cost per kilowatt at Brighton, which was some £125, was reduced to £50 per kilowatt, as at Leicester, the standing charges constants in the paper would be largely reduced. He thought too much money was often spent in steam-pipes and in condensing plant. He also thought that Liverpool could claim the lead in the matter of differential charges.

Mr. Faraday Proctor, of Bristol, thought that the maximum-demand indicator did not meet all the requirements of the case, as it took no account of the time when the load occurred. He believed in encouraging rather the day load, as the extra cost then was least. He did not consider Mr. Sayers's figures as to the effect of the maximum-demand indicator conclusive, as the same effect was found at Bristol, where these indicators were not used. He had used the Kapp meter for differentiating the day and night loads. By this one-third of the current was shunted past the meter in the daytime. The only objection of this was that the total unit supplied was not indicated.

Mr. Hammond dealt largely with the costs of production, and said the principle that Mr. Wright laid down was a very important one for the industry. Mr. Wright told them they should not divide their costs with their total number of units and apply that figure, as they found it in one of the technical papers called *Lightning* that had been referred to, where they found that the total cost and the cost per unit were so much. Without wishing to detract from the value of these figures, he would point out with regard to them that they were simply a reproduction of the Board of Trade returns. With this apology for the tables, he said they found them very misleading. It was misleading to say with regard to Hastings that its cost of production was 3·88 Well, now, the directors of the Hastings company were offered some arc lighting, and they found it could not be produced under 2·5, so they said they could not take it because their average cost was 3·88. He should advise them to take it at the price, because it could be done far below the average cost, which they thought was the cost of supply. They owed a great debt to Mr. Wright that he had drawn attention to the fact that it was erroneous to say that the arc lighting had been carried on at a loss, and that the incandescent light had got to bear the loss on the arc lighting. In making their comparisons of cost between one works and another they had not taken into account the cost of producing the extra units. In Brighton in 1894, as compared with 1893, the cost of producing extra units was 1·33 per unit as compared with the total cost of production 1·81, and it was by taking the cost of the additions that they really got at the cost of production. He could not follow the president in the way in which they should divide it. He agreed with Mr. Wordingham that it was not fair to put on the running charges only a portion of the coal bill, etc.

Mr. Andrews (Hastings) said for the past two or three years they had been getting £25 per lamp annually. That meant that they had received £1,300, and the capital outlay on lamps had been £6,500. They paid 6 per cent. for their money, and allowing 4 per cent. for depreciation, that made a total of 10 per cent. on the capital outlay, which must be deducted from the £6,500. Carbons, trimming, etc., cost £350 a year, so that in the end they had £300 for the 110,000 units, and they could not possibly supply it at that. He had had some difficulty with regard to the charge, but he had adopted a system similar to Mr. Wright's. Each consumer would be charged a uniform price—6d. per unit for all current, and an additional charge of 1s. per lamp per quarter for each 8-c.p. lamp demanded, but the demand must be indicated.

Reply to Discussion.

The **President** replied briefly to the discussion, and said his fuller reply would appear in the *Proceedings*. With regard to Mr. Mavor, Mr. Wordingham had pointed out that there was a very great "nigger" in the system he suggested, and he gave an illustration where a man only had to burn a very little more to get a big reduction in his bill. A system which permitted that was undoubtedly wrong. He was very glad to see that Mr. Sayers had found the running cost per unit to be ·8d., which it was the object of the paper to advocate. With regard to Mr. Siemens's discovery that 8d. a unit was practically equivalent in a house to gas at 3s., he should like to point out that 4½d. per unit would eventually become universal, and would prove how utterly gas was out of it if the 3s. gas was equal to electricity at 8d. a unit. Perhaps Mr. Ellis would state in his written notes whether the lower charge would reduce the profit. With regard to debiting the whole of the wages to standing cost, that was a question of stations, and it was very easily determinable whether this system was right by the analysis he had proposed. At Brighton they found that for three years their wages charges did not diminish in May compared to January. That was the test. This was the result of experience, but any station could test it and find out whether the wages were less in the three lightest months of the year than in the three heaviest. He knew his salary was not less in May than it was in December, and with regard to his clerks they had as much correspondence and meter reading in January as in December. With regard to the wages again, he did not see what he could do with his men. He could not send them away as the load went off. Mr. Hammond seemed to imply that the wages load varied in proportion to the ampere load. If they divided the total amount of wages in the three heaviest months by the difference of units, that would give them the running cost of wages. He wanted to get rid of arbitrary assessment in the matter of cost. With regard to Mr. Dawbarn, he would give the figures he suggested in his written reply. He quite agreed with Mr. Geipel as to keeping capital down first, but he lost sight of the fact that they must take into account the miles of streets supplied by electricity. In Leicester the cost per kilowatt was much less than at Brighton. At Brighton there were 85 miles of mains, and he did not suppose there were so many at Leicester. They must take the area of the district supplied in estimating the capital cost; and the capital cost per kilowatt was not sufficient. It ought to be capital cost per kilowatt multiplied by the miles of streets supplied, and, therefore, Mr. Geipel's deductions as to the alterations in this curve due to lower capital cost would be slightly modified if they took the number of miles of streets supplied. Mr. Proctor suggested that the cost of supplying electricity in the daytime was less than at night, because there were no capital charges to provide for; but why should they not charge day consumers with the station charges as much as the night consumers? Why should they not debit the day consumers with the cost of continuing to run? They could not supply them without capital. [**Mr. Proctor:** If they got day consumers their capital charges would be reduced all round.] In conclusion, the president said their time was very limited, and he would reply further to the discussion and Mr. Andrews in the *Proceedings*. At Hastings it seemed that they studied their items much more carefully than they did elsewhere.

Mr. Andrews: I wish they didn't.

Cable Specifications and Tests.

This was the title of the paper written by Mr. Joseph A. Jeckell, borough electrical engineer, South Shields. The author said he was of opinion that it was fairer and better both for contractors and corporations if it was clearly stated in the specifications exactly what cable was required, and the tests could then be more conveniently specified. Tinned copper wire having 100 per cent. conductivity could now be obtained. The best way to get over the difficulties of difference between the conductive resistance of cables was to specify the resistance the cable has to have, and the number of strands of which it is to be composed, leaving it to the manufacturerers to put in 100 or 98 per cent. of copper as they liked. If a concentric cable was required, care should be taken to specify that the copper resistance of the outer conductor should be the same as the inner. High insulation was not necessary *per se*, but it was necessary in the

Digitized by Google

case of rubber cables to ensure good material and workmanship. The pressure test was advisable in all cables, but more especially compound ones. The bending test was advisable in specifications for compound cables. With regard to the laying of cable mains, he felt it was an advantage that the makers should lay their own, but should not do the trench work, which would be more conveniently done by the corporation. Whatever tests were specified as having to be conducted at the maker's works should be repeated as far as possible after the cables had been laid and jointed up. The insulation tests would be made after one month's electrification, but there was no reason for this generally accepted time limit. It was advisable, but awkward at times, to obtain a long time guarantee.

DISCUSSION.

Mr. Wordingham said the mains were the vital part of the electric lighting system, and therefore they must have them all in good order. Although they wanted a good system of mains, they not only wanted a good article, but a cheap one, and they should give manufacturers an opportunity of showing the best they could do. They must have a perfectly definite specification. If they wanted rubber they must specify for rubber, and if they wanted anything else they must specify it. The material, if it was good of its kind, must have an exceedingly high resistance. If the insulation resistance was low, it was bad; but if it was high, it did not necessarily follow that it was also good. He did not attach much importance to insulation tests (although he acknowledged that they were necessary), in so far as they showed that the rubber was bad. They ought to have mechanical tests with all cables. It was perfectly easy to get a bad cable with a high resistance. He did not quite agree that it did not matter what the purity of the copper was, because if they had to put in more material to get a higher resistance they would have a heavier cable. As to stranding altering the resistance of the cable, no doubt it did; if the copper was well in contact it lowered it, but if the strands were insulated, more or less, then it would increase it. As to pressure tests, he thought the small end from the cable should be subjected to a breakdown test and then that a moderately high pressure should be put on the cable itself.

Mr. A. B. Mountain, of Huddersfield, said that in certain cases the contractors could not be responsible for damage. Thus, where faults occurred in street boxes or manholes, he believed that most of the faults in cables were caused by the drawing-in process, and considered that lead-covered cables laid direct in the ground were the safest.

Mr. Hardie McLean, of Oxford, was of opinion that the resident engineer should superintend the drawing-in process and thus find the faults as they were caused.

Mr. H. Talbot, of Nottingham, believed in the guarantee system. He had some £8,000 worth of cables laid in Nottingham three years ago, and still held some £800 of the contractors' money. If contractors would thus guarantee their work, the municipalities were safeguarded.

Mr. Alexander Siemens, speaking from a consumer's point of view, commended Mr. Jeckell on his excellent paper, which, however, did not go quite far enough. The author spoke of rubber and impregnated jute cables as if they were the only types of cables existing. We were indebted to a representative of one of the fire insurance offices for the demand for pure rubber cables, as the pure rubber next to the copper enabled the manufacturer to obtain easily the unnecessarily high insulation resistance demanded. Pure rubber had been proved to be most unserviceable and unable to withstand alternate wetting and drying, as often required in practice. Of course, for house wiring those objectionable conditions did not apply. He thought much damage had been done to the industry by the crazy desire for extremely high insulation resistance. Still, it must be remembered that pure rubber on the cables raised their price, and hence the maker's profit. Greater stress, he thought, should be laid on the uniformity of the insulation used. Another instance he noticed in the paper was that the author recommended cables of 5,000 megohms per mile without specifying the size of the cable. That was useless and unscientific. Impregnated jute cables gave satisfactory results, but generally could not withstand a spark discharge so well as the rubber. He gave an example of a cable in the Charing Cross-road which had stood 2,400 volts for the last five years, but which when installed could not take 3,000 volts without sparking across. His firm, in search after a non-hydroscopic insulator, had produced a material which, when placed on a ·25 square inch cable to a thickness of $\frac{3}{32}$in., stood a pressure of 60,000 volts for half an hour. By the Board of Trade regulations this thickness should only stand 7,500 volts. It was afterwards wrapped round a bar of 3in. radius several times and straightened out again without injury as it stood 50,000 volts after it. The after processes consisted of stripping the lead off, wetting, baking, and boiling without breaking the cable down under 50,000 volts. He believed that all specifications should contain a clause for suggestion on the part of the contractor and for alternative tenders.

Mr. Stuart Russell did not consider that the insulation test was of great value, except as a means of showing how the mechanical treatment of laying affected the electrical condition of the cable. He would also emphasise the value of uniformity in the insulation as a guide to the selection of good cables.

Mr. W. Arnot agreed that the specification of the insulation resistance per mile without giving the dimensions of the cables was absurd. In an old specification he had seen it stated that the insulation resistance of $\frac{1}{4}$ square inch cable should be 2,500 megohms and that of a $\frac{1}{2}$ square inch cable should be 5,000 megohms, which were the converse of what should be. He thought the resistance per mile should be specified rather than the section of the copper.

Mr. Nesbitt said the paper before them was an excellent one. He thought a fourth class of engineers should be added to those enumerated by the author—*i.e*, those who did not care what they had so long as it did what they wanted it to do. He, too, believed that lead-covered cables laid directly in the earth were the most reliable. The thickness of the lead covering had not been referred to, and it was an important subject, as corrosion often took place. Mr. A. H. Preece specified that the thickness of the lead should be a certain definite proportion of the diameter of the finished cable over the lead. As regarded paper cables, they had supplied some low-tension cables to Manchester to stand 100 volts, these had a thickness of only ·07in. insulation and had stood 10,000 volts after being wrapped round a 2ft. barrel and straightened out again.

Mr. T. Callender objected to engineers specifying definitely what they wanted and then taking something else. The engineer should be bound over to take what he had specified, or to insert a clause giving the contractor option to send in an alternative price. He agreed that there could be a great difference of resistance between the inner and outer conductor of a concentric cable due to outer conductors not being in contact. Under the Board of Trade regulations a wire smaller than 20 gauge could not be used, hence this want of contact was bound to occur. As regards the durability of pure cables, he had supplied some to Mr. Crompton in 1882, which he believed had given satisfaction ever since and been in constant use. He approved of Mr. W. H. Preece's specification of specific resistance of the insulating material used. He thought that more attention should be paid to the quality of the material used in the armouring of cables.

Mr. R. E. Crompton believed that the main cause of failure in cables was that of chemical action. This was especially so in vulcanised cables, where a slight modification of vulcanising process seemed to make all the difference between a good and bad cable. He thought that the experience gained in tropical countries was most useful in this respect, as the trying nature of climatic conditions accelerated the faults. He thought they would get help from the cable manufacturers in drawing up their specifications, and could assure the meeting that the cables referred to by Mr. Callender had given no trouble.

Mr. Raworth said that Mr. Jeckell had drawn out the manufacturer in a wholly unexpected way. That was the first meeting he had ever attended in which the cable manufacturer had given any information. He personally believed in specifying the quality of the insulating material in resistance "per acre of 1in. thickness."

The reply to this discussion will be given by Mr. Jeckell in writing, as the time at the disposal of the meeting had practically lapsed.

Electricity Works Records.

The paper by Mr. A. B. MOUNTAIN, A.M.I.E.E., borough electrical engineer, Huddersfield, on this subject was next taken. In this paper the author said he only attempted to give an idea of the chief records required. Some such records must be kept by almost every engineer, and in certain electricity works the necessary clerical assistance was not provided, so that the engineers had not the means of getting the items of expenditure in detail which enabled them to make comparisons with other works. The forms illustrated in the paper were the general records that were absolutely required in the works. The cost-sheet showed the several items to be recorded for one month's expenditure. The time-sheet showed the time of any man, and the cost of such time and the work on which he was employed. The engine-room cost-sheet would give the details required from the engine-room, with the general stores required and the chief points which it was desirable to have a record of. There were also tables to give records of high and low tension mains and plant testing, and a daily log-book, a line-test record, and a consumers' register. There were many engineers, said Mr. Mountain, who had devoted considerable time to the matter of keeping these records and tests, and he thought it would be very desirable for the executive committee to obtain further information as to how electricity accounts should be kept so that a comparison between works might be more accurately made. He suggested that it would be better to get a committee appointed to go into the matter, and bring up again at the next convention a more complete form covering the whole of the points in connection with the subject of his paper. He moved a resolution to that effect.—Mr. STEWART seconded, and said he thought it was a subject well worth enquiring into.—The resolution was agreed to.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

MUNICIPAL ELECTRICAL ENGINEERS.

One of the ablest of municipal electrical engineers, discussing the questions of the most important information required by this branch of the profession and the best way in which they could serve each other, contended that it was in the consideration and explanation of details. The broad principles of central-station design are fairly well known, but each station has certain details characteristic of itself, the examination of which will stamp the engineer as original and capable or fashionable and incompetent. There is no need to disguise facts which are well known, for already some of the engineers have placed themselves a head and shoulders above others, mainly because the first class know their work—are able men with original ideas; while the second class fear to proceed upon their own responsibility, and have to consult others in times of difficulty. The same thing holds good in every branch of every profession, so that there is no singularity in finding the condition amongst electrical engineers. It has been also found among other professional men that associations for the purpose of reading and discussing professional papers and the periodic meeting of members conduce to a levelling up process, whereby the average type of the professional man is raised. The benefits that accrue from such an association are both direct and indirect. The direct action is in the direction of raising salaries. The better the men the wider their experience, and the greater their knowledge the easier can they command higher salaries. It pays the employer to give a higher salary to the better man, because he thereby gets his work turned out more cheaply. He saves more in better organisation and attention to details than he pays in higher salaries. This is the human way of looking at the matter, and it is no good pretending that men will go out of their way and spend time and money in making themselves more valuable to their employer without a hope of adequate return. We then assume it proved that associations of this kind do increase the average value of men's work, and that they are better paid for the services rendered. So far as we have been able to gather, this first convention (why not call it meeting?) has produced a number of good papers and excellent discussions. Nothing previously, for example, has brought out so clearly the arguments for and against 220-volt lamps, or the position of municipalities in regard to internal fittings. As regards the former question, its want of flexibility is its principal opposing force, in that it does not lend itself to the general use of lamps of small candle-power, while such lamps are held to be necessary to enable suppliers to compete with gas. The supporters of the higher pressure may, on the other hand, say that the makers of lamps will probably find a way out of their difficulty, and that, assuming the move to be in the right direction, the lamps will be forthcoming when it is found they must be. They contend that finality is not reached even in the making of incandescent lamps. So the matter rests at present. If any maker can satisfactorily provide lamps of small candle-power, there seems to be little doubt but

Digitized by Google

that many stations would quickly adopt the higher pressure. The second question mentioned is one of exceeding difficulty. We do not think powers will ever be given to permit of house-to-house supervision and dictation, and we are of opinion that the resolutions proposed by Mr. Wordingham, however desirable from one point of view, will lead the new association into difficulties which at the present time they would do well to avoid. Let us just glance at one point which has probably been overlooked by the members. They are in the position of being officers in places where the electric light has been adopted. They little know the difficulties encountered by those go-ahead members of town councils who desire their towns to adopt the light. By introducing any system of dictation and espionage these difficulties will be increased, and ratepayers will have their backs set up to oppose tooth and nail any attempt to municipalise the light. It is the interest of the profession generally to avoid everything that may tend to prevent an increased rate of progress. But we will not dwell upon the matter. Another subject admirably debated was that of cables. Almost all, if not quite all, the makers were represented, and probably the discussion elicited in a shorter time more information of a practical character than has ever been given before. We must congratulate the association upon its successful meeting.

MUNICIPAL ELECTRICAL ASSOCIATION.

(Concluded from page 657.)

DISCUSSION.

Mr. McLean then proceeded to criticise the paper. He said there was no mention in it as to goods taken back to the store which had previously been taken from it. In the revenue account no details were given as to the different items of revenue. The author gave the total at the end of the month, but did not tell them how his revenue was got—whether from arcs, from charging, from accumulators, or from incandescent lighting. All these points ought to be made quite clear. He did not think it was a good idea to have so many small forms when they could have in their engine-room one form to include them all. There were some forms that were not mentioned in the paper, notably a comparison sheet for the consumers, which he thought would be very useful. The author made a good point when he said that the mains should be entered in such detail that the cost of any extension might be at hand for ready refesence. In conclusion, he said he would forward to the committee one or two forms useful in getting out the list of records.

Mr. Wordingham thought the only possible way of showing the mains was on large maps. He did not think that simply recording the length from box to box was of very much use as a record. He did not think it was possible to have a weekly record of expenses. They did not incur them weekly, neither did they pay them weekly.

Mr. Jackson suggested that in these various records, both public and private, a little more attention should be paid to the units generated.

Mr. Hammond thought this was essentially a paper to be discussed in committee. The matter was one of the very greatest importance, and he should be glad to place his set of books at the disposal of the committee.

REPLY TO THE DISCUSSION.

Mr. Mountain briefly replied to the discussion, and said he thought it was not necessary for him to go into all the points now that the matter would be considered by a committee. In a paper like this he did not think he could have gone into every detail; he only touched upon the more important, and therefore several were left out. It would be noticed that in the engine-room cost-sheet he had mentioned ashes. He thought that it was a very important point. In Brighton, for example, they were paying a good deal for coal, and it was very good and with little ash. In the North, where they got it much cheaper, it was of a common quality and made a lot of ashes.

This concluded the morning business, and the meeting adjourned.

Visit to Islington.

The afternoon meeting was held in the Vestry Hall, Islington, where Mr. VARLEY, in the absence of Mr. Lambert (the chairman of the Electric Lighting Committee), received the members with a congratulatory speech on the successful programme they were getting through. The vestry hall, however, was not so convenient for the meeting as the theatre of the United Service Institution, and the street noises prevented certain speeches from being heard. The first paper was by Mr. John Hesketh, A.M.I.C.E., M.I.E.E., electrical engineer to the Queensland Government, late borough electrical engineer, Blackpool, and Mr. John H. Rider, A.M.I.C.E., M.I.E.E., borough electrical engineer, Plymouth, on

Combined Electric Lighting and Traction Plant.

Mr. RIDER stated that he felt his position keenly, as his partner in the paper had been compelled to leave the country, though he was happy to say, not for this country's good, but for his own. The most important question dealt with in this paper was that of increasing the day load in the electric lighting station by supplying tramways with the current they required. The undertaking would thus reap the benefit of having a certain amount of the standing charges spread over the two departments, and the plant could be available for the double purpose. He referred to the Continental practice and to the towns which had already adopted the combination of electric light and traction plant. In the paper two systems were suggested—the first to have one station containing two distinct plants and to economise coal and the staff required; the other to use the lighting machinery to supply the tramways, and to provide for the overlapping demand by accumulators. The first would tend to increase the peak of total output, while the other would enable the engineer to level up the curve considerably.

DISCUSSION.

Mr. Gay, of Islington, was the first speaker, and he congratulated the authors on the excellency of their paper. The great advantage of the day load so obtained by traction demand could not be over-estimated, but he did not think the plan feasible in London. The Board of Trade would not allow a vestry to supply outside its own area, and the number of authorities therefore concerned in the running of a tramway system would prejudice the smooth working of the same. Still, in provincial towns the extra demand would be of great value, and enable the gas interest to be even more keenly fought than at present. If a special plant and special staff were required he could not see such a great saving, but he thought that motor transformers with heavy flywheels would enable the lighting machinery to be employed. Even then he was not sure that the fluctuation of load would not affect the pressure on the lighting mains. He did not think that storage batteries would be able to stand the sudden and heavy fluctuations without deterioration.

Mr. S. Z. de Ferranti agreed with the last speaker that the difficulties in introducing the combined working in London would be very great. In provincial towns the difficulty would be only in electrical matters, which could be overcome. Still, at Manchester, where they had 440 volts across the outer mains, he doubted if trams could be supplied from these mains without affecting the lighting service. Motor transformers with heavy flywheels would, he thought, overcome this difficulty, and accumulators would also assist. If the original supply was by alternating currents, non-synchronous motors should be used to give the transformers a range of speed, and these motors should not be designed to give too strong a drag for a slight variation of speed. The advantages would be very great, as practically 14 hours' heavy load could be added to the present lighting load.

Mr. C. H. Wordingham agreed with Mr. Ferranti that the traction work could not be supplied by the same mains at Manchester. This was specially debarred, as the centre wire of the five-wire system was earthed, so that two trolleys would have to be used, as an earth return would not be possible. He did not believe in saddling the system with inefficient constant-current transformers, but advised the use of distinct generating plants supplied from the same boilers as the lighting machinery.

Mr. E. Manville thought it would be difficult to overcome the divided interests existing in London, but it was not so in the provinces. He was concerned in two undertakings where they had guarantees of heavy day loads before the stations were opened. The first was at Shoreditch, where the Vestry will supply some half a million units per annum to an underground railway company at the low rate of 1½d. per unit. This was only a day load, as the supply would be discontinued when the ordinary lighting load came on the station. Again, at Swansea the Corporation had agreed to supply the local tramway company with current at the following rates: the total amount per annum

Digitized by Google

to be not less than 400,000 units nor more than 750,000 units, at a price varying from 2d. to 1½d. per unit. This load would be continuous, and would be supplied during the heavy lighting loads by stationary accumulators. He referred to the Hamburg station, where the tramways were supplied by the electric light company with six million units per annum at 1d. per unit. The total cost of generation of this amount was ·710d per unit, and the remaining fraction covered the interest and depreciation on the plant.

Mr. W. Arnot could not see the objection to the different London vestries each supplying the trams in their own parishes if the charge was by meter. He also had seen the Hamburg station when his committee made their memorable tour of inspection There the direct-current generators at 600 volts, direct coupled to triple-expansion engines were used for the traction work, and similar machines at 390 volts for lighting purposes on the three-wire system. Two of these 300-volt machines were connected in series if the traction plant was pressed. Separate feeders and mains were used for each purpose, and he did not think it possible to combine the two sets of mains without upsetting the lighting pressure.

Mr. Philip Dawson said there was no objection on the tram way engineer's part to the suggested combined working so long as the distribution was kept separate. At Rome where alternate currents were used, batteries were employed to take the load where the two supplies overlapped. He thought that the corporations supplying traction work from their electric light stations should be bound under comparatively heavy penalties to give a regular and constant supply. Storage batteries in the station could well be used to take the load at times if they were provided amply large.

Mr. Jacobs said that the batteries at Rome had given satisfaction, and the current taken from them varied from 20 to 400 amperes, as the gradients in some parts were very steep, going up to 1 in 12. He thought a flywheel might be put on the motor transformer, which might help the sudden leads, and which, however, did not hurt the accumulators. He considered that secondary batteries should be more used in light circuits to prevent small fluctuations.

Mr. Higginbottom said there had been a good deal of debate in Manchester as to whether they should use their electric light station for traction purposes, and one thing only had been decided, which was that the trams should be worked by electricity.

Mr. Mordey said that the last time he heard the authors of the paper speak on the subject Mr. Hesketh said that he had given up all ideas of getting a decent day load, and was turning his attention to perfecting an arrangement by which the very small day load could be economically supplied. He understood that Mr. Rider had put in batteries with a small alternate-current transformer to take this day load at Bolton. He was glad to see that they were again taking up the subject. He considered that two sets of plant must be used to meet the great fluctuations He then explained the great advantage the alternate-current motor had over the direct-current as regards ease in preventing a large starting current, and regretted that the alternate-current motor at the present time was not sufficiently advanced to be easily applicable to traction purposes. He would also point out that the use of motor generators on the supply stations in London would enable them not only to work a general system of tramlines, but also would assist each other in the lighting loads in case of breakdown.

Alderman Ellis, of Portsmouth, said that they had a scheme for combined working under consideration, and proposed to charge 1½d. per unit for traction supply.

Mr. Wilkinson stated that his experience of similar work in Canada showed that the two systems of feeders must be kept totally distinct. He would point out that the motor generators in sub-stations helped to meet the Board of Trade requirements as to drop in the return circuit. The density of this current in America often gave rise to various inconveniences. He was not at all sure that sufficient flywheel action could be obtained to prevent the reaction on the engines through the transformers if both traction power and light were supplied off one machine.

Mr. Pearson, of Bristol, as chairman of the Electric Lighting Committee, regarded with jealousy any other suppliers of electric energy in his district. At Bristol he had recommended that the Council take the matter up and supply all tramway extensions from their station. Unfortunately, the Council would not go to that length, but they decided to consult Mr. W. H. Preece on the subject, and he opposed extension of the electric tramways until they had his report on the subject. He had taken great interest in all electric questions, and keenly felt that he had only up to the present discovered his own ignorance of this subject He thought that the sooner his *confrères* on the Corporation shared his feeling of ignorance the better. They had at Bristol allowed ample room for the traction machinery in their extensions. He hoped the scientist would help them in some such way to transform science into sovereigns for the benefit of the ratepayers, as unless the ratepayer was pleased the speaker might lose his opportunity to continue his electrical studies. Still, it was a purely business matter, and if the electric light stations could not supply the tractive power more cheaply than could be done by a separate power station, it would be most unfair to force them to take the supply.

Mr. Ruthven Murray remarked that they had a good day load at Worcester, and that the chairman of the Electric Light Committee had done everything to encourage this load. Unfortunately the price charged—only 1d. per unit—was too small to admit of profitable working, and a considerable amount of money was lost last year on this account.

A Gentleman from Liverpool then addressed a few remarks to those around him, and he was inaudible on the other side of the room.

REPLY TO DISCUSSION.

Mr. Rider, in the course of a brief reply, gave Mr. Ferranti the credit of introducing the flywheel on the motor transformer shaft, which he first heard of about a year ago. [We believe Mr. Kapp proposed the same idea in a debate before the Civil Engineers in 1893.—ED. *E. E.*] Mr. Rider also pointed out that nothing in the paper would suggest that their system of mains would do for both electric lighting and traction purposes. Mr. Hesketh and himself had no idea of making that suggestion when they wrote their paper.

On the Organisation of an Electricity Works Staff.

Mr. E. T. RUTHVEN MURRAY, city electrical engineer, Worcester, read the following abstract on this subject: As the success of an electricity works depends in no small degree upon the staff directly engaged in running the plant, the organisation of this staff requires considerable judgment on the part of those responsible for their engagement. It behoves the engineer to be particularly careful and far-seeing in engaging a staff to keep the wages item of the standing charges as low as is consistent with safety, since when the output is small this item is a heavy burden on the young station. No hard-and-fast rules can be laid down as to the number of men necessary on the staff, as this will depend upon the individual characteristics of the electricity works. Among other matters to be considered which have a direct bearing upon this are the size of the works, their designs, the system employed, whether a direct-current battery station or an alternating-current supply, and, of course, whether the supply is constant or intermittent. Unless there be a large demand throughout the night for public lighting, or an intermittent demand both by day and by night for motors, the small battery station may be able to give a constant supply with only one watch of men, whereas the alternating-current station will require three eight-hour watches. How many men are required for a watch will depend upon the size of the works; but probably it will be necessary to have at least one engineer in charge, one driver, and one fireman. Regarding assistant engineers, it seems only right and proper to employ them, as one can hardly expect either the engine-drivers or switchboard attendants to have the necessary technical training to enable them to take entire charge of the works during the absence of the chief engineer; moreover, it is obviously necessary to give some one man the general responsibility of the proper working of the station during each watch. In organising the staff, it is most important that the engineer be allowed to choose or recommend men for appointment, and that the men know to whom they are responsible. It is the greatest mistake for the committee who have charge of the department not to allow their chief engineer a free hand in this respect, and internal troubles in electricity works have often been due to this cause.

DISCUSSION.

Mr. Albert Gay considered the subject was too much affected by local conditions to admit of general conclusions. The reduction of the staff should not be pushed to extremes, as a stand-by should be provided. Longer hours and two shifts instead of three did not mean a saving, as the men would demand overtime after eight hours at the rate of time and a half. He considered eight hours amply long enough for any man to work in an electric light station. He did not believe in fitter-drivers, and thought one man to spare should always be provided in the all-night shift in case of sudden illness on the part of any one man.

Mr. Dawbarn advised that electrical connection should be made from the station to the houses of the officials and men, as was now the case with fire stations, but his remarks did not obtain the approval of the resident engineers, who objected to be called every time a gauge glass or a fuse went.

Mr. J. F. L. Crosland asserted that the firemen should be most carefully selected, and that the idea that any man was fitted to put coals into a furnace was very erroneous From his experience of boiler work he would say that nothing was more detrimental to the boilers or wasteful in fuel than employing inefficient stokers. The same remark as to inefficiency applied, of course, also to engine-drivers.

Mr. Arnot contended that the staff should all be under the direct control of the engineer-in chief, and that the committee should exert no influence in this matter. He had seen the fruits of an engineer being obliged to employ the inefficient and insubordinate friend of an individual committeeman.

Digitized by Google

Mr. A. B. Mountain advocated the continuity of policy with the staff, and always preferred to train up youths for the subordinate positions. He believed in having pupils who could take a shift when required, and in educating his own meter men, etc., and at the same time paying them a fair wage.

Alderman Higginbottom said that at Manchester they had fought out this trouble, and after some inconvenience had left the matter for six months in Dr. John Hopkinson's hands. He had sent them their present engineer, Mr. Wordingham, for the time and since then matters had been left entirely in the latter gentleman's hands. All but the second and third engineers were responsible only to the chief engineer, and the system had worked admirably.

Alderman Norman supported the above view, and said that no one on his committee would dream of interfering with the authority of their engineer over his staff.

Alderman Pearson did not agree with the last two speakers. The Electric Lighting Committee were alone responsible to the Corporation, and, as chairman, he would not waive his rights under this responsibility. He of course would not in any way interfere with the duties of his respected resident engineer in the selection of the staff in the ordinary way. The fact of the appointment being finally in the hands of the committee rather strengthened the engineer's position when an inefficient man was recommended by some member of the Corporation. He would then be relieved of the personal refusal, which otherwise might lead to trouble.

REPLY TO THE DISCUSSION.

Mr. Ruthven Murray replied that he had not recommended a reduction of the staff, but rather wished to point out the minimum staff which would be required in one watch in a new electric light station. He also had only advocated the use of the fitter-driver in the early stages, when the output at the station did not warrant a larger staff.

The meeting then terminated, and arrangements were made for certain of the members to go over the Bankside station of the City of London Electric Lighting Company, and also over the Davies-street station, after they had inspected the works at Islington.

A vote of thanks was passed by acclamation to Mr. Varley for his kindness in presiding, and also to the Islington Vestry for lending their hall for the purposes of the meeting.

To-day (Friday) a general meeting of members and associates will be held, after which a visit will be made to Brighton, where the convention will terminate.

ELECTRIC AND MAGNETIC RESEARCH AT LOW TEMPERATURES.*

BY J. A. FLEMING, M.A., D.SC., F.R.S., M.R.I.

During the last four years much time has been spent by Prof. Dewar and by me in the prosecution of a joint research on the principal electric and magnetic properties of metals at very low temperatures. Some reference has already been made in previous discourses by Prof. Dewar to portions of this work,† but the special object of the present lecture is to extend these descriptions, and put you in possession of the latest results in this department of the low-temperature investigations. It will be convenient to discuss the several divisions of it in the order in which they have engaged our attention.

One hundred and sixty-seven years ago, Stephen Gray, pensioner of the Charterhouse, in conjunction with his friend Granvile Wheler, stretched a packthread 300ft. long over silk supports and demonstrated that an electrification of the thread at one end spread instantly over the whole mass, but that if metal wires replaced the silk no electrification of the thread was possible. This experiment undoubtedly formed the starting point for the first definite recognition of the necessity for a classification of bodies into insulators and conductors, a distinction which Gray's brilliant contemporary, Dufay, extended and confirmed, and for which he and Desaguiliers coined these familiar terms.‡ Gray's contributions to knowledge as an epoch-making discoverer have received less notice from scientific historians than their real value deserves. It is less easy to state who first noticed that the powers of conduction and insulation were greatly affected by temperature. Cavendish in 1776, however, was perfectly familiar with the fact that warm solutions of salt conduct electricity better than cold,* and made measurements of the relative resistances of an iron wire and a salt solution marvellously accurate when we consider that his means of measurement was the comparison of electric shocks taken through the bodies to be examined.

Not until after the invention of the battery and galvanometer was it clearly proved that differences exist between the conducting powers of metals; but by Davy, Becquerel, Ohm, Pouillet, Fechner, and others all the fundamental facts were ascertained, and the classical researches of Wheatstone and, later, of Matthiessen gave us the accurate laws and constants of electrical conduction. By these investigations it was shown that in the case of electric conduction through metallic wires of uniform sectional area their total resistance was proportional to the length inversely as the cross-section, and also proportional to a specific constant for each material called its *resistivity*. Moreover, it was found that this resistivity was considerably affected by temperature, generally being increased in metals by rise of temperature and decreased for carbon, electrolytic liquids, and many badly-conducting bodies.

Although much knowledge of the behaviour of pure metals and alloys in regard to electric conduction has thus been accumulated, we considered that it would be of great scientific interest to examine with care the changes occurring in the conductivity of these bodies, or reciprocally in their resistivity, when cooled to temperatures of 200deg. or more below the Centigrade zero by the aid of liquid oxygen and liquid air.† Knowing the great influence of very small quantities of impurity on this quality, our first attention was directed to obtaining samples of alloys and metals in a state of great chemical purity, in giving to wires drawn from them a suitable form, and in devising a convenient support, or holder, by which the electrical resistance of the wire might be measured when immersed in liquid oxygen or liquid air, either in quiet ebullition in an open vessel or under reduced pressure in a closed one. It will be unnecessary to dwell on difficulties surrounding the preparation of these accurately-drawn metallic wires of pure metals. Suffice it to say that our obligations to Mr. George Matthey, Mr. Edward Matthey, Mr. J. W. Swan, and other friends were very great with respect to this portion of the work. The final outcome of all failures was the production of a resistance coil of the following form: Two thick wires of high-conductivity copper about 3mm. or 4mm. thick are bent, as shown in Fig. 1, and wrapped round the lower part

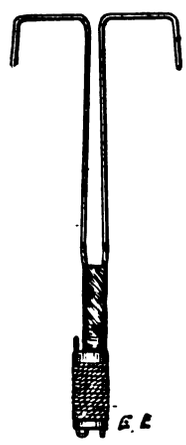

FIG. 1.

with a cylindrical sheath of thin vulcanised fibre laced to them by a silk thread. On this sheath, which generally had the form of an oval cylinder, a paraffined silk cord was spirally wound so as to leave a helical groove. In this groove was coiled the resistance wire of known length and section, and its ends were attached by solder to the ends of the thick copper leads. The wire was wound a little loosely in the groove so as to allow for the great contraction which takes place on cooling, and yet the wire was exposed so as to take up instantly the temperature of the bath, whilst at the same time the mass of material to be cooled down was rendered as small as possible. The length of wire employed was generally about one or two metres, and the diameter from about one-twelfth to half a millimetre (·003in. to ·02in.). These mean diameters were measured by the microscope micrometer at about 50 to 100 places for each metre length of the wire. Having thus prepared a great collection of resistance coils of pure metals and alloys each in the form of a wire

Transactions*, 1720, vol. 31, p. 104; 1731, vol. 37, p. 18; 1732, vol. 37, p. 285; 1735, vol. 39, p. 16; 1736 vol. 39, p. 400. See also Dufay, *Phil. Trans.*, 1733, No. 431, p. 258.

* See "The Electrical Researches of Cavendish," edited by Clerk Maxwell, p. 324.

† Almost the only experimental work previously done in this subject seems to have been that of Cailletel and Bontz (*Journal de Physique*, July, 1885) on the resistance of metals at – 100deg. C., using ethylene as a refrigerating agent, and a research by Wroblewski on the resistance of copper at very low temperatures (*Comptes Rendus*, 1885, vol. ci., p. 161).

Digitized by Google

of known length and mean diameter, the next operation was the measurement of their resistance at definite temperatures. For the sake of those not fully familiar with the details of electrical measurement, a moment's digression may be made to explain two of the principal methods in use. Becquerel's work was chiefly conducted with the differential galvanometer. In this instrument two coils of wire of exactly equal length are coiled on one bobbin, in the centre of which hangs a small magnetic needle. The current from a battery divides at one point and flows along one path through the conductor under examination and through one coil of the galvanometer. The other portion of the current flows through a wire of variable length, called a rheostat, and through the other coil of the galvanometer, equal in every respect to the first coil, but circulates round the needle in an opposite direction to that of the current in the first coil. Hence, if the currents are of equal strength, the needle is not disturbed at all from its zero position. We can make these currents equal by adjusting the length of the wire of the rheostat so that its resistance is equal to the resistance of the coil being tested. By this means it is easy to verify all the ordinary laws of conduction. We can, for instance, show at once that by warming an iron wire in hot oil its resistance is increased, whereas in warming the carbon filament of an incandescent lamp its resistance is decreased.

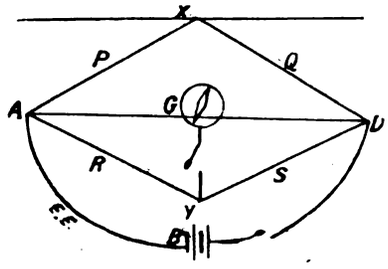

FIG. 2.

This method is not generally so convenient as the arrangement first described by Mr. Hunter Christie to the Royal Society in 1833, redevised 10 years later by Wheatstone, in 1843, and which has been always curiously misnamed the "Wheatstone's bridge," even in spite of Wheatstone's own declaration that he did not invent it.* In this arrangement (see Fig. 2) the current from a battery, B, has two paths open to it by which to complete its circuit, and we employ a galvanometer with a single coil to discover two points on these two circuits which are at equal potentials. When these two points are connected the galvanometer needle is undisturbed, and it is a simple matter to show that under these circumstances the numerical values of the electrical resistances of the segments of the two circuits are to one another in simple proportion—that is, P is to Q as R is to S. In actual work, one form which this arrangement takes is that known as the slide-wire bridge (see Figs. 3 and 4), and which is before you. In this construction the battery current flows partly through a uniform wire stretched over a scale and partly through a standard resistance, S, and the resistance, R, to be tested placed in parallel with it. We employ a galvanometer to connect the middle point between R and S with some point on the slide wire, and we can always find a point on the slide wire such that no current flows through the galvanometer. The ratio of the unknown resistance, R, is to that of the known standard resistance, S, in the ratio of the lengths of the two sections into which the contact-piece divides the slide wire. Hence, R is determined in terms of S. Another form of this appliance, in which all three arms of the bridge consist of coils of wire capable of being joined in series with each other by plugs, is most commonly used, and it was a most carefully adjusted Elliott bridge of this last pattern which we employed.

All our resistance measurements have been reduced to express them in terms of the international ohm as defined by the Board of Trade Committee and obtained by reference to standard coils carefully standardised for us at Cambridge. By this means the whole of our wires were measured at five definite temperatures—viz., at about 200deg. C.; at the temperature of boiling water, 100deg. C.; at the temperature of melting ice, 0deg. C.; at the temperature of solid carbonic acid melting in ether, which gives a temperature of about 78deg. C.; and at the temperature of liquid oxygen boiling under a pressure of 760mm., which gives a temperature at − 185deg. C. In this last case the coils were immersed in liquid oxygen contained in suitable vacuum-jacketed vessels. In this connection I should like to express with due emphasis the opinion that none of this low-temperature research would have been possible at all without the assistance of Prof. Dewar's most valuable invention, the glass vacuum-jacketed silvered vessel. For much of this work it has been necessary to employ many litres of liquid oxygen and air at a time and to be able to keep it for hours in a state of perfect quiescence and absolutely constant temperature, and in no way could this have been done without this beautiful and scientific device.

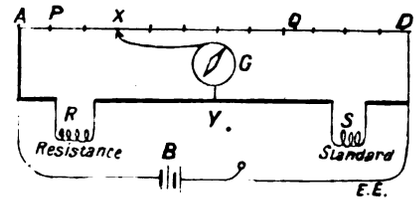

FIG. 4.

Before describing the results of these experiments it may be interesting to exhibit a few of the principal facts. The most striking of them is the very great reduction in electrical resistance or increase in conductivity experienced by all the pure metals when cooled in liquid air. Here, for instance, are two coils of iron wire. Balancing them on the bridge, we find them to be of exactly equal resistance; but if one of the coils is cooled in liquid air, its resistance is reduced to about one-tenth of its resistance at the ordinary temperature of the air. We may also compare the resistance of these two similar iron coils when one is placed in boiling liquid air and the other in boiling water. The resistances, instead of being in the ratio of 2 to 1, are now in the ratio of 1 to 12. Again, if we take two wires, one of pure iron and one of pure copper, of exactly equal length and equal section, we find that at ordinary temperatures (15deg. C.) the iron wire has about six times the resistance of the copper; but if we cool down the iron wire in liquid air to 186deg. C., still keeping the copper coil at the ordinary temperature (15deg. C.), we now find that the iron coil has actually become a much better conductor (about 30 per cent. better) than the copper.* On the other hand, if we examine the behaviour of this coil of German silver, which is a copper-zinc-nickel alloy, or of this platinum-silver coil, we find that the cooling through 200deg. has but little effect upon its electrical resistance. We thus see that whilst pure metals have their electrical resistance immensely decreased by cooling to the temperature of liquid air, alloys generally do not experience anything like so great a change. A word or two must next be said on the manner in

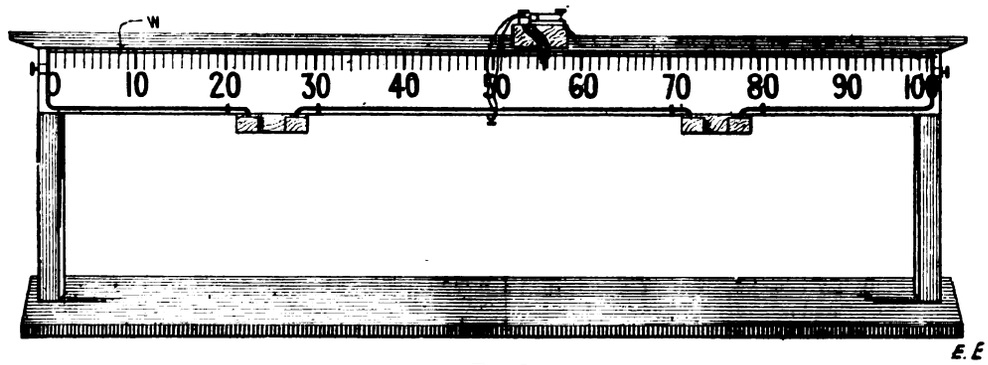

FIG. 3.

* See *Phil. Trans.*, 1833: Mr. S. Hunter Christie on "The Experimental Determination of the Laws of Magneto-Electric Induction." See also Wheatstone's "Scientific Papers," p. 129, "An Account of Several New Instruments for Determining the Constants of a Voltaic Circuit" (*Phil. Trans*, vol. 133, p. 303, 1843).

* The exact resistances of the coils used for the experiment were as follows: Iron at 16deg. C. = 7·003 ohms and reduces to 0·711 ohm at − 186deg. C. Copper at 16deg. = 1·169 ohms; reduces to 0·2033 at − 186deg. C.

Digitized by Google

which we have represented graphically all the results of our experiments. We desired to delineate lines on a chart so as to express the change in specific resistance of all our metals and alloys in terms of temperature, and the question then arises, How was the temperature measured? You already know that an ordinary thermometer, whether mercury, alcohol, or air, would be useless to measure temperature at temperatures at which even air liquefies under ordinary pressure.

The employment of the constant-pressure hydrogen thermometer with reduced pressure would have given us temperature readings very approximately those of the absolute thermodynamic scale, but the experimental difficulties of its use would have been enormous. We preferred to use the platinum resistance thermometer and to express our temperatures in platinum degrees, as follows. Our experience has shown us that a pure, soft annealed platinum wire may be cooled as often as necessary to the lowest attainable temperatures, and yet will always have the same resistance when measured again at other constant temperatures. Availing ourselves of this fact, we have used in all this work a low-temperature platinum thermometer made in the following way: A well-annealed platinum wire is made into a resistance coil, as already described. Its resistance is carefully measured at the temperature of boiling water (100deg. C.) and melting ice (0deg. C.). From these measurements we construct a scale of temperature as follows: A horizontal line (see Fig. 5) is taken on which to mark off temperature, and any two points are taken on this line and divided into 100 equal parts. At these extreme points perpendiculars are set up proportional to the resistance of the platinum wire at 0deg. C. and 100deg. C. respectively, and through the tops of these perpendiculars a sloping straight line is drawn until it cuts the axis of temperature. The graduation of the horizontal line is continued in both directions on the same scale as the sub-division of the line between the points marked 0 and 100. To measure and define any other temperature—say, for instance, the boiling point of liquid oxygen under a pressure of 760mm.—

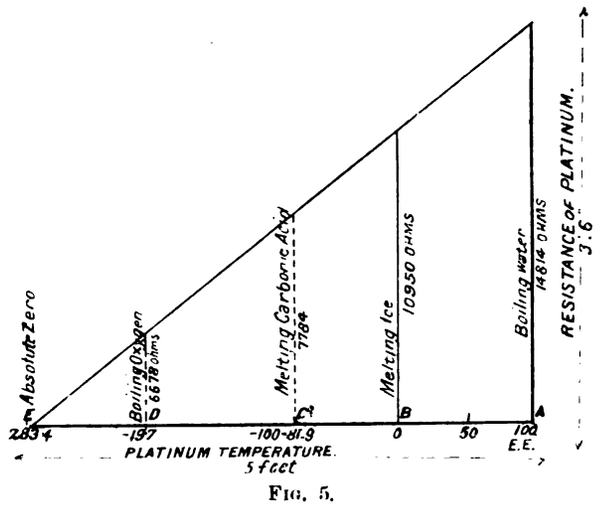

FIG. 5.

we have simply to measure the resistance of the platinum wire in the oxygen. We then look out on the chart the ordinate which has the same numerical value as the resistance of the wire in the oxygen, and at the foot of that ordinate we find a number—viz., (−197)—which is the temperature of the liquid oxygen on this platinum scale. Two questions then arise: first, Do all annealed platinum wires give, when used in this way, the same numerical values for definite and identical temperatures? The answer to this is, Nearly, but not quite. In the case of two thermometers much used by us the difference was about half a degree at −100deg. C., the boiling point of liquid ethylene. Into this matter it is not possible here to enter more fully; suffice it to say that we have invariably reduced our temperature measurements to one standard thermometer. The second question is equally important; it is, What is the relation of the scale of temperature so defined to the absolute thermodynamic scale, or, which is very nearly the same thing, to the scale of temperature defined by a constant-pressure hydrogen thermometer? If the air thermometer and platinum thermometer readings are made to agree at 0deg. C. and 100deg. C., then a temperature which would be called 50deg. on the Centigrade scale would be denoted by 50·4 (nearly) on the platinum thermometer scale, and corresponding to the −78deg. on the Centigrade scale, which is the temperature of carbonic acid melting in ether. The platinum temperature by our standard is −81°·9, and corresponding to −182deg. C., which is very nearly the Centigrade temperature of liquid oxygen boiling at the normal pressure of 760mm.; the platinum temperature by the same standard is −197deg. The conversion of these numbers representing low temperatures in platinum degrees into the numbers representing the corresponding absolute thermodynamic temperatures is a work we have reserved for a future research*, but meanwhile it may be said that there is no method of measuring low temperatures which is so easy of application and so accurate as that depending on the use of a platinum thermometer. All our work has been ultimately referred to one standard platinum thermometer, which we call P_1. A suggestion may here be made. There is no reason why the Board of Trade electrical laboratory should not possess a standard platinum thermometer defining officially platinum temperatures, or absolute, for all time, and with which other platinum thermometers could be easily and very accurately compared.

(To be continued.)

AN ANALYSIS OF TRANSFORMER CURVES.†

BY CHARLES J. HUGUET.

This paper describes a number of experiments in regard to the distortion of primary current curves on open secondary. This was one of the most noteworthy features of Prof. Ryan's paper on "Transformers," read before the institute, and Prof. Ryan ascribed this distortion to hysteresis. The same opinion seems to have been held by Fleming, Steinmetz, and every other writer since that time, with the single exception of Prof. Rowland.

Dr. Sumpner had previously shown that, assuming hysteresis absent, a variation in the value of the permeability will superpose on the sinoidal magnetising current a system of higher harmonics, causing it to become a symmetrically peaked curve. Prof. Rowland, however, went further, and declared that the presence of the distorting harmonics is due, not to hysteresis, but to change in permeability, the effect of hysteresis being capable of representation as a simple resistance. However, he simply expressed this theory mathematically without giving any experimental verification, and it is doubtless for this reason that the results of this paper have not been accepted in their entirety. This apparent conflict of opinion seemed to warrant further investigation, and it was the object of experiments conducted by the writer at Tulane University in June, 1895, to throw light on this question by analysing the current curve into its various components.

The method employed in the measurement of the instantaneous values was essentially similar to the telephone method described by Prof. Nichols in his "Laboratory Manual," a galvanometer being substituted for the telephone. Runs were made at different voltages and rates of alternations from which the data were sufficient to discriminate the eddy from the hysteresis losses. By dividing the watts lost by eddies by the E.M.F. applied, the effective current due to eddies is obtained, and the ratio of this to the aforesaid E.M.F. is the conductance due to eddies.

If the instantaneous values of E.M.F. be multiplied by this conductance, and the resulting eddy-current curve be subtracted from the original current curve, the remainder will be the hysteresis curve—*i.e.*, the curve that would be derived from the hysteresis loop. If in the same way we determine the conductance due to both eddies and hysteresis—*i.e.*, if we represent the hysteretic loss as one due to a simple constant resistance, and subtract the effective current curve thus determined from the original current, the remainder will be a true wattless current, since the curve subtracted itself accounts for the watts lost. The wattless remainder is very fairly symmetrical with respect to the flux curve, and is of the peaked character to be expected with permeability variable and hysteresis absent. A similar treatment of Prof. Ryan's curve yielded a wattless remainder of similar character. These results seemed to verify Prof. Rowland's theory, at least approximately. But equally strong proof is afforded by several curves in the paper of Steinmetz, "On the Laws of Hysteresis" (Part III.).

The writer concludes that for sinoidal E.M.F.: (1) Hysteresis may in all respects be replaced by a constant resistance if the hysteretic characteristic be the quadrant of an ellipse. (2) This condition is approximately satisfied

* Callendar has shown that over a wide range of temperature, from 0deg. C. to 700deg C., the difference between the platinum temperature and the air thermometer temperature is a parabolic function of the absolute temperature.

† Read before the American Institute of Electrical Engineers, May 20, 1896. Abstracted by the *Electrical Engineer* (New York).

for moderate ranges of magnetisation (such as are used in practice), in reasonably good iron, and the higher harmonics are negligible. There will usually be a particular range that will give a nearly perfect approximation. On contraction of the range, the hysteretic current becomes more pointed than the sine, and on expansion beyond the critical range more flattened than the sine. (3) The increased distortion of the hysteretic current for higher ranges will cause an increase in the higher harmonics, but the rapid diminution in the permeability on approaching saturation will cause a much greater increase in these harmonics, so that even at higher ranges the distorting influence of hysteresis is comparatively slight.

As a final conclusion, then, we may say that Prof. Rowland's hypothesis that the higher harmonics in the transformer for sinoidal E.M.F.'s are due, not to hysteresis, but to variation in permeability, and that the effect of hysteresis may be represented by a constant resistance, is approximately correct, for reasonably good iron, is very nearly correct for the moderate ranges used in practice, and may, under certain conditions, be absolutely correct.

RESULTS ACCOMPLISHED IN DISTRIBUTION OF LIGHT AND POWER BY ALTERNATING CURRENTS.*

BY W. L. R. EMMET.

(Concluded from page 634.)

Fig. 6 shows diagrammatically the distribution of voltage with a given balance load on a two-phase four-wire circuit, and on the same circuit with one wire discarded, the third being used as a common return for the two sides of the system. S F and E G represent the two generated voltages on the four-wire two-phase system. F F′ and G G′ represent the E.M.F.'s of self-induction in the lines of the separate two-wire branches of the circuit. F′ F″, G′ G″ represent the resistance drop in the two branches. E F″ and E G″, which are still at right angles, represent the two voltages at the end of the line. The other diagram in Fig. 6 shows the condition on the three wire circuit. A B and A C represent the generated voltages in quadrature.

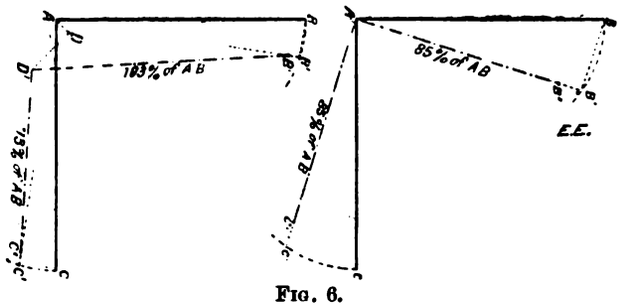

FIG. 6.

C C′ and B B′ represent the volts of self-induction in the outside conductors. C′ C″ and B′ B″ represent the volts' drop by resistance in these wires. A D is the resistance drop in the third wire and D D′ is the E.M.F. of self-induction in the third wire. Since this wire carries 40 per cent. more current than the others, A D is 42 per cent. greater than C′ C″, and B′ B″ and D D′ bear the same proportion to C C′, and B B′. The length of D′ B″ and D′ C″ represents the voltages on the two sides of the system at the end of the line. The angle C′ D′ B″ is the phase relation of these two circuits, and is less than 90deg. Thus with balanced load the sides of the system are neither equal or in quadrature.

The figures are so proportioned as to represent a circuit of "O O" B. & S. wire operated at 125 cycles with 10 per cent. resistance drop on the four-wire system, and the same load and the same distance with three wires. With 1,000 volts at the generator in both of these cases, we would have 850 volts on each side with the four-wire system, and with the three-wire system 730 volts on one side and 1,030 on the other. This assumes aerial lines with ordinary spacing of wires. In addition to the systems above described for distributing power by induction motors, we have other means of power distribution by alternating current. The synchronous motor, for certain classes of work, is highly efficient and reliable, and is extensively used, although it will not fill all the requirements of general power distribution. The rotary converter also fills a very important place in the engineering work of the day.

A synchronous motor is simply an alternating dynamo whose functions are reversed. They may be used either on single-phase or polyphase circuits. In its simple form, a synchronous motor has no power of starting itself on a single-phase circuit. On a polyphase circuit it starts with more or less torque as an induction motor, and will come to synchronism. As a rule, the starting of synchronous motors is not vigorous, and is accomplished by a large draught of current; hence their applications are limited. A rotary converter is a synchronous motor of suitable construction, whose armature windings, besides being connected to collector rings, are also connected to a commutator. As the machine revolves at synchronous speed, brushes collect direct current from the commutator, this current being partly rectified and partly generated by the machine. This machine deals in direct and alternating currents and mechanical power; supply it with any one of the three, it will deliver either one or both of the others. It is most efficient when filling its functions as a converter from alternating to direct currents. Its capacity is then greater and its efficiency higher than when it runs as a generator or as a motor.

To illustrate the use of the rotary converter, I will describe an application now under consideration. The company in question is operating three stations. One of these is very large and centrally situated, with condensing water and every facility for the cheap generation of current. Each of the other stations is about two miles from the main station; both work non-condensing. One of these stations delivers current only on the direct-current three-wire system, while the other, in addition to similar work, carries a considerable arc light load. In this case the following plan is considered:

At the two smaller stations rotary converters would be installed, and would deliver only direct current in one case, while in the other they would also act as motors to operate arc machines through a countershaft, to which they would be belted with clutch pulleys. Suitable step-down transformers would connect the rotary converters to a high-tension line leading to the main station. At the same station three-phase generators of large capacity would be installed. These generators would be designed to deliver both three-phase alternating currents to step-up transformers and also direct currents at about 250 volts to the outside conductors of the three-wire system. They would be directly coupled to engines. These machines would deliver current simultaneously, in any proportion, to the direct-current three-wire system, to the rotary converter, or to lines distributing three-phase power. It is proposed to operate these machines at a frequency of 25 cycles per second, this being well adapted to the direct-current work and also to three-phase power distribution. In this plant an entirely independent control of direct-current pressure within a wide range would be necessary at the main and sub-stations. This would be effected without the introduction of idle currents by the use of a novel form of three-phase induction regulator connected to the alternating leads of each rotary converter. These regulators would give a wide range of adjustment without any moving connections, and would greatly simplify the operation of the plant, and also increase its economy, since the losses introduced by the regulators themselves are very small, and since conditions of general economy are always maintained. Thus a single engine could carry the whole load of the city at certain times.

Another interesting illustration of a combination of alternating and direct currents is found in a case now under consideration. A company controls about 3,000 h.p. in water at a distance of 11 miles from a large town. It is proposed to instal three-phase 60-cycle generators in 600-kilowatt units. The current from these generators will be transformed to 10,000 volts and carried over three wires to a city sub-station centrally placed. Here large step-down transformers will be installed, delivering current to

* Paper read before the Nineteenth Convention of the National Electric Light Association, May 5, 6, and 7, 1896.

Digitized by Google

2,000-volt lines, which extend all over the city and carry motors and lights in outlying parts. In the same station two large Corliss engines are now in operation, and are belted to clutch pulleys on a countershaft, which operates some arc machines and other load. To this countershaft it is proposed to couple with a clutch a large synchronous motor which will be connected to the 2,000-volt lines. When the water supply is ample, the engines will be shut down and the motor will run the shaft. When the water is low, or more power is required, the engines will be run and the synchronous motor will then act as a generator, running in parallel with the transmission line. In the central part of the town it is proposed to instal a system of three wire mains and a large storage battery. This battery would be installed in a second sub-station, conveniently placed. It would be charged from a pair of direct-current machines, directly coupled to a synchronous motor operating from the 2,000-volt lines. The direct-current machines would be used in connection with the batteries for supplying the three-wire system. The plan here outlined has many very positive advantages.

The pressure on the 2,000-volt system can, within certain limits, be controlled at the sub-station by adjustments of the field of the synchronous motor. With telephone communication to the power-house, the control will be perfectly easy. The peak of the lighting load being borne by the battery, the generators can be loaded nearly to their full capacity with motors during the day. At night they will charge batteries, using water which would otherwise run to waste. In both the plants described the cost of labour would be very small, one man being enough to operate each of the sub-stations mentioned. The saving of labour in operation should be kept constantly in view in all engineering plans. Some of the greatest advantages in modern apparatus lie in its adaptability to such saving.

An infinite variety of conditions exists in different cities, and the question of electrical distribution must be carefully studied in each case in order that money may be invested to the best advantage. An intimate knowledge, both of the apparatus available and of the commercial conditions, is necessary to an intelligent decision in such cases. It is only through the exercise of intelligence and judgment of a high order that the best results can be obtained.

LEGAL INTELLIGENCE.

THE SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

In the Chancery Division on Tuesday, Mr. Justice Romer gave judgment in the case of the Electric Construction Corporation *v* South Staffordshire Tramways Company, which came before the Court at the latter end of April, and occupied five days in the hearing. The action was brought to recover certain sums due under an agreement dated February, 1892, and the defence set up was that the Court could not enforce specific performance. The defendants further counterclaimed that the agreement was not binding upon them, asking for rescission and relief by way of damages.

Mr. Eve, Q C., and Mr. Theobald were for the plaintiffs; and Sir F. Lockwood, Mr. Oswald, Q C., Mr. C. E. E. Jenkins, and Mr. T. D. Munns were for the defendants.

His **Lordship** said that, seeing how disastrously to the defendants the contract in question had resulted, he was not surprised that the shareholders should view it with reluctance, and endeavour, if possible, to escape from its provisions, and, having regard to the way in which the defendants had been, as it would appear, defrauded by their officer, Wain, and their solicitor, Ebbsmith, that they should imagine it was brought about by sinister influences and dishonest purposes, and that it was not in the true interests of the defendant company. But the contract had been carried out by the plaintiffs, and ought not to be set aside unless the defendants established a case that would justify the Court in refusing to hold it binding upon them. That the defendants had not done to his satisfaction, and, notwithstanding his sympathy with the company, he must hold the contract binding upon the defendants. The main defence was that the contract was fraudulently brought about, and was unfairly onerous on the defendants and impossible to be carried out by them. It was also suggested that the contract was *ultra vires* of the defendants, but no sufficient reason for this had been shown. The defendants also relied on the fact that debentures were parted with by the defendants before the plaintiffs had made any payments or done any work under the contract. But, although that might have shown imprudence, it could not be laid hold of as invalidating the contract after the plaintiffs had made the payments and done the work contracted to be made and done by them. As their main contention the defendants had broadly urged that the contract was brought about as part of a far-reaching fraudulent scheme of Wain and Ebbsmith, but they had not established that the contract was fraudulent or fraudulently brought about by Wain and Ebbsmith or by any other person or persons. Its terms were the subject of careful consideration by both companies and of considerable negotiations, which had been fairly and honestly conducted. The contract was not a profitable one for the plaintiffs, and, although it was onerous on the defendants, they could not have inaugurated a system of electric working without aid or without entering into some such contract. The defendants were advised in the matter by their engineer, Mr. Dickinson, a gentleman of great experience and skill, and, notwithstanding the reflections which had been made on him on behalf of the defendants, his Lordship saw no sufficient reason for holding that Mr. Dickinson did not honestly advise them at the time. The only provision in the contract to which strong objection could be made was that enabling the plaintiffs to bring the agreement to an end if the then directors of the defendant company, or any of them should, otherwise than by death or voluntary resignation, cease to be directors. But at this time the frauds of Wain were not known, he being then generally recognised as a gentleman of high character and of great experience and skill as a tramway expert. The provision might have worked very hardly against the defendants but it had not been acted on, and it was impossible, therefore, to make the existence of this provision a ground for upsetting the contract. As regarded Clause 3, his Lordship said he did not think the payments made to Mr. Dickinson were a bribe to him. There was no ground for thinking Mr. Dickinson did not fairly do his duty by the defendants. The defendants said that as the cost to the plaintiffs of working the electric tramways was about 3d a mile, the 4½d. mentioned in Clause 16 was excessive, but if the plaintiffs had been obliged to exercise the power given to them by Clause 16 of bringing the agreement to an end the risk and loss to them would or might have been very great, and his Lordship thought the 4½d. might fairly be taken as a sum properly compensating them under the circumstances. His Lordship accordingly declared the contract binding on the defendants, and that under Clause 16 it was ended on December 14, 1894 and on that footing he directed the account to be taken, the defendants undertaking to account for all costs occasioned by them. He would adjourn further consideration to chambers, with liberty to apply and with liberty to apply generally. As to the costs up to and including trial, the defendants must pay the plaintiffs' costs of the action. The counterclaim wholly failed, except as to the sums the plaintiffs had undertaken to account for; he therefore ordered the defendants to pay the costs of the counterclaim, except so far as they had been increased by the plaintiffs not admitting the sums to be accounted for by them, and in respect to those he ordered the plaintiffs to pay them and for them to be a set off.

Mr. Oswald said that as this was a matter of life and death to the defendant company, he would ask for a stay of execution, if the appeal was brought in reasonable time

Mr. Justice Romer then directed the account to proceed; but if taken before appeal was heard, gave liberty to apply again.

ELECTRIC LIGHTING AT EXETER.

In the Chancery Division of the High Court last week, before Mr. Justice North the case of Franklin and Gould *v.* the Exeter Electric Lighting Company, Limited, was heard.

Mr. Jenkins, for the plaintiffs, the trustees for the debenture-holders in the company, said the company had entered into an agreement with the Exeter Corporation for the sale of their undertaking to the Corporation for £7,500, which agreement would take effect on 30th inst. The only assets of the company cutside this sale to the Corporation consisted of book debts and a few chattels, amounting altogether to about £1,000, so that the whole assets of the company amounted to £8 500 As the debentures amounted to £12,000 there was a considerable shortage. The company was in difficulties, and there were debts which it could not pay. One of the unsecured creditors was suing the company, and the debenture-holders' trustees had brought this action to enforce the security under the debenture deed and to ask for the appointment of a Mr. Knill as receiver with power to manage until the sale to the Corporation was carried into effect.

Mr. Broughton Edge said he was instructed to offer no opposition on behalf of the company.

Judgment was given for the plaintiffs for the amount of the security, Mr. Knill being appointed receiver and manager of the company, with power to act at once.

COMPANIES' MEETINGS AND REPORTS.

ELECTRIC TRACTION COMPANY, LIMITED.

An ordinary general meeting of this Company was held on Friday at 16, Great George street, Westminster, Mr. R. E. Farrant presiding.

The **Chairman**, in moving the adoption of the report, which has already been published in our columns, said that the business of the Company to which the directors were at present devoting their attention was the construction and equipment of the Central London Railway, which would run through the heart of London, from Shepherd's Bush to the City, a distance of 6½ miles. This

Digitized by Google

work was undertaken in pursuance of a contract with the railway company, dated June 18, 1895, under which the Traction Company was to acquire the necessary land and to construct and equip the railway with rolling-stock, to be worked by electrical power to the satisfaction of the railway company's engineers, the whole to be completed and delivered by December. 1898. The dominant feature of the report was that, having settled the price to be paid for the bulk of the property to be acquired, and having let the contracts for almost the whole of the heavy work, they were satisfied that the undertaking could be carried out within the original estimates, and they had no reason to doubt, unless something altogether unforeseen occurred, that they would complete the railway within the contract time The stations would be 14 in number, and were placed in the best positions to secure the greatest amount of traffic along the line of route. The Act of Parliament authorising the construction of the line prohibited the making of any openings in the roadways, so that all shafts must be sunk at the station sites Their first work, therefore, was necessarily the acquisition of the property required for the stations and the depôt at Shepherd's Bush. The acquisition of valuable property having frontages on what Mr. J S. Forbes once described as the greatest traffic thoroughfare in the world was by no means a simple matter, because of the many interests involved—freeholders, lessees, sub-lessees tenants, trade interests The work of dealing with these claims had been pushed forward with such energy that at the present time more than four fifths of the total number of claims had been settled or had been adjudicated upon by an arbitrator or a jury. He did not think it expedient to state publicly what these settlements had cost them, for there were still about 20 cases to be dealt with. The land estimates were originally framed some years ago, and since then the cost of investments had increased largely, and they had consequently had to pay very heavily for some of the properties of an investment character. Of course, the settlement of the amount of a claim did not mean that they at once got possession. In about half of the total number of cases the purchases had been completed, and they now had complete possession of three station sites, so that there was nothing on this score to prevent the actual work of construction from being very shortly commenced. The line from Shepherd's Bush to the Bank had been divided into six sections, and it was decided to ask for tenders for each of these separately, and a list of responsible contracting firms was settled with the engineers who should be asked to tender. They had had a good reply to the invitations. and they had given the sub-contracts as follows: Sections 1, 2, and 3 Shepherd's Bush to the Marble Arch Mr. J Price; sections 4 and 5, the Marble Arch to the Post Office, Messrs. Walter Scott and Co.; and section 6, the Post Office to the Bank, Mr. G. Talbot. Shareholders would remember that in connection with the railway there was to be constructed under the open space in front of the Mansion House and the Royal Exchange a system of public subways, which would also give access from the public streets to the Bank Station. The general idea of this system of subways was approved by the City authorities some time ago, but before they could invite tenders for the work the detailed plans had to be settled. This was a work requiring the utmost care and attention, but they had succeeded in presenting plans which secured the acceptance of the Commissioners of Sewers. The sub-contract for this work had been given to Mr. G. Talbot. The station in the vicinity of Davies-street and the extension from the Bank to Liverpool-street were receiving their attention, but he would not dwell on these matters as they were still in the stage of negotiation.

Mr. T. Davidson seconded the adoption of the report, and it was carried unanimously.

The chairman and retiring directors having been re-elected, resolutions confirming the arrangements as to their remuneration were carried without dissent.

IMPROVED ELECTRIC GLOW LAMP COMPANY.

A meeting of this Company was held on Saturday at Cannon-street Hotel, but the Press were not admitted. The improved glow lamp, it may be mentioned, is one in which there is a mirror deposited on the stem portion of the lamp so as to reflect the light downwards.

BOURNEMOUTH AND DISTRICT ELECTRIC SUPPLY COMPANY, LIMITED.

The fifth ordinary general meeting of this Company was held at Bournemouth last week, Mr. Aymor H. Sanderson presiding.

The **Chairman**, in moving the adoption of the report and financial statement, said that the great increase in the use of electric light in Bournemouth was, he thought, due in some measure to the steps taken from time to time by the directors to cheapen and popularise the light, while at the time sparing neither trouble nor expense in order to ensure its quality and reliability. For the purposes of the expansion to which he had made reference he said considerable loans to meet the capital requirements of the Company had been obtained from the County of London and Brush Provincial Electric Lighting Company, Limited, and the time was not far distant when, in the opinion of the directors, it would become advisable to incorporate the amount of these loans into the permanent capital of the Company by readjustment of the capital account. When this took place, Bournemouth investors would be afforded an opportunity of further increasing their interest in the Company. In a well-to-do place like Bournemouth there was no reason why the greater part of the Bournemouth Company's capital should not be held locally, and he thought local investors would do well to embrace the opportunity of subscribing for the Company's shares and debentures when the opportunity was afforded them, so that the Company might continue to be a local company in fact as well as in name.

Dr. J. A Hosker seconded the adoption of the report, and it was unanimously carried.

Dr. Hosker was re-elected a director of the Company, and Mr. R. H. Marsh, chartered accountant, was re elected auditor.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ecija (Spain).—The Municipal Authorities of Ecija want tenders by July 2 for a system of electric lighting for the town.

Cherbourg.—The French Ministry of Marine are asking for tenders, by June 18, for the supply of a quantity of electric fittings.

San Sebastian (Spain).—The San Sebastian Tramway Company ask for tenders, by July 1, for the application of electric traction to their line.

Benevento (Italy).—A concession for installing and working the electric lighting of the town of Benevento is open to be tendered for up to June 20.

Bucharest.—The Municipality want tenders by July 1 for the electric lighting of a portion of the Boulevard Coltzea. The estimate is about £3,680.

Utrera (Spain)—Tenders are wanted by the Municipal Authority of Utrera for the installation of electric lighting. The last date for receipt of tenders is July 1.

Lisbon.—The South and South-East Railway Company, Largo de S. Roque 22, Lisbon, want tenders by June 15 for 12 tons of galvanised iron wire for telegraphs.

London, S.E.—Tenders are required for complete installation of electric lighting. For particulars apply by letter to Mr. H. Freeman, 44, Knatchbull-road, Camberwell, S.E.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years Tenders should be sent in by August 31.

Brussels.—The Belgian Telegraphic Department want tenders for the purchase of old telegraphic instruments and stores (31 lots). Particulars obtainable at the Brussels Bourse, and tenders to be in by June 24.

Spandau.—Tenders are wanted at the Royal Small-Arms Factory for 900 incandescent electric lamps by July 17. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21) Spandau.

Ocana (Spain).—The Ocana Municipal Authorities are open to receive tenders, up to June 30, for the electric lighting and water supply of the town. The annual payment suggested is 10,000 pesetas (about £400). Ocana is in the province of Toledo.

Paris.—Tenders are wanted for the supply of a dynamo for the municipal generating station at the Buttes Chaumont. Application for permission to tender must be made at the Hotel de Ville before June 14, and tenders must be in by June 17.

Brussels.—Tenders will be received shortly (the exact date is not yet announced) at the Brussels Bourse for the material and work necessary to start an electric lighting installation at the fifth section of the central locomotive construction works at Malines.

Brussels.—On June 17 there will be a reallotment of contracts for the conversion to a system of electric traction of about 12½ miles of local light railway. Application for particulars (price 1fr.) should be made to la Société nationale des chemins de fer vicinaux, rue de la Science 28, Brussels.

Paris.—Tenders are wanted by the French Government Telegraphic Department for the supply of about 125 tons of galvanised iron wire, 3,000 cross-pieces (iron), and 100,000 screws and various accessories. Particulars are obtainable at Rue de Grenelle 103, Paris, and application for permission to tender must be made before June 15. Tenders must be in by June 25.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Burnley.—The Corporation invite tenders for the supply and delivery at their electric lighting station, Burnley, of armoured concentric underground cables. Specification, schedule of quantities, and form of tender may be obtained on application to Mr. W R Wright, borough electrical engineer, on payment of £1. 1s., which will be returned on receipt of a *bonâ fide* tender. Sealed tenders, endorsed "Tender for Cables," and addressed to the Chairman of the Electric Lighting Sub-Committee, Town Hall, Burnley, must be delivered on or before the 24th inst.

Huddersfield.—Tenders are required for the supply and erection of a 92-unit direct-current dynamo and of a 3½-unit combined steam-engine and dynamo at Trafalgar Mills, Huddersfield, for Messrs. Learoyd Bros. and Co. Copies of specifications and general conditions can be obtained from Messrs. Shepherd and Watney, engineers, 71, Albion-street, Leeds, on receipt of a cheque for

Digitized by Google

£1. 1s., which will be returned on receipt of a bona fide tender. Tenders, endorsed "Electric Lighting," must be addressed and delivered to Messrs. Learoyd Bros. and Co., Milnsbridge, Huddersfield, before noon on 19th inst.

Glasgow.—Tenders are invited by the Caledonian Railway Company for the supply of telegraph and electric appliances, etc., for 12 months from August 1, 1896. Specifications and forms of tender and any other necessary information may be obtained on and after June 1 from Mr. Jas Lorimer, superintendent of stores, Caledonian Railway, Charles-street, St. Rollox, Glasgow. Patterns may be inspected on and after June 1 from 9 a.m. till 5 p.m. at the Company's Stores, Charles-street. St Rollox (Saturdays 9 a.m. till 1 p m.). Tenders, endorsed "Tender for Stores," to be lodged with Mr J. Blackburn, secretary, 302, Buchanan-street, Glasgow, by June 15.

Leeds.—The City Council invite tenders for an electrical installation sufficient for the working by the overhead system of haulage, a double track of tramway seven miles long. The work will be divided into the following contracts: (1) poles for supporting trolley wire; (2) underground conduits and conductors; (3) trolley wire and attachments; (4) motorcars; (5) accumulators and switches; (6) steam engines; (7) dynamos, switchboards, and accessories Tenders, endorsed with the number of the contract, must be sent in, addressed to the Town Clerk, Town Hall, Leeds, by June 22 Particulars, plans, forms of tender may be had (on payment of a deposit of £2 2s. for each contract, which will be returned on receipt of a bona fide tender) from the City Engineer, Municipal Buildings, Leeds; or from Dr. John Hopkinson, F.R S., 5, Victoria-street, Westminster, S W.

Hampstead (London).—Tenders are wanted for the extension of the electric lighting station in the parish stoneyard, Lithos-road, Finchley-road, N W., for the Vestry of St. John, Hampstead. Drawings and specification can be inspected, and bills of quantities and form of tender obtained, on application to Mr. Arthur P. Johnson, vestry clerk, Vestry Hall, Haverstock-hill, Hampstead, N.W., on and after 15th inst., between 10 a.m. and 4 p.m., and upon payment of £2. 2s, which will be returned if a bona fide tender is sent in. The person or firm whose tender is accepted will be required to enter into a written contract and to provide two sureties for the performance of contract. The expenses of contract and bond are to be paid by the contractor. Sealed tenders, endorsed "Tender for Extension of Electric Lighting Station," must be delivered at the vestry clerk's office by 4 p m. on 25th inst.

Shoreditch.—The Vestry invite tenders for the supply and fixing of insulated conduits, cables, switch and fuse boards, and all sundry fittings and materials for installing the electric light in their new dust destructor and electricity supply station, Coronet-street, Shoreditch. Specifications, with forms of tender, can be obtained from the consulting engineers Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, on payment of three guineas, which sum will be returned on receipt of a *bonâ fide* tender. Contractors whose tenders are accepted will be required to enter into a formal agreement, under seal, with sufficient sureties for the due fulfilment of their respective contracts. Trade union rates of wages and hours to be observed. Sealed tenders, endorsed "Electric Lighting—Tender for Wiring," to be sent by 4 p.m. on June 16 to Mr. H. Mansfield Robinson, clerk and solicitor, Town Hall, Old-street, E C.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following: (*a*) the amount of capital which the applicants are prepared to subscribe; (*b*) the system which it is proposed to establish; (*c*) the mileage of lines to be laid; (*d*) the fares to be charged; (*e*) the frequency of the service; (*f*) the length of the license required by applicants; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about 12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

Bucharest.—The result of the enquiry into the tender of contracts held on March 26, 1896, having led to no definite approval, notice is given that a fresh enquiry will be held on June 24, 1896, at 10 a m. in the Town Hall Bucharest, when sealed offers and tenders will be received for the lighting of the outlying zone of the town, by such a system as will not necessitate any canalisation, and which may be adjudged to be most advantageous of all the systems proposed, with a view to replacing the 3,265 petroleum lamps now lighting the streets and squares of the outlying districts of the town The enquiry will take place in accordance with the conditions of contract established by the management of the Public Works Department and approved by the Town Council at its meeting held on January 24, 1896. Particulars of the conditions may be obtained at the offices of the Agence Havas, 96, Queen-street, Cheapside, London, between 11 a.m. and 4 p.m. The contract will be granted for a period of five years dating from the time of its approbation and acceptance by the Board of Enquiry, or for a longer period, according to the proposals and conditions of tenders submitted. Competitors must indicate in their tenders the points provided for in clause 6 of the conditions of contract respectively. Intending competitors are requested to attend on the day and at the hour above mentioned at the Town Hall, prepared with a deposit in 15,000fr. in cash or in Government stock to be placed in the Public Pay Office, in order to be admitted to take part in the competition.

RESULTS OF TENDERS.

Paisley.—The Town Council have accepted the Brush Company's tender for wiring the Clark Town Hall at £844.

Edinburgh.—The tender of Messrs. J. Waldie and Sons for the supply of coal to the electric lighting station has been accepted.

Rochdale.—For installing the electric light at the free library, for the Town Council, the tender of Messrs. Peers and Co., Manchester, has been accepted. The amount is about £500.

Perth.—The offer by Messrs. A. Westwood and Son, Perth, to put up telephones from the gasworks to Princes-street Station, in connection with the working of the oil-gas contract, and the conveyance by the oil-pipe of tar from the works to the station for £17. 18s. has been accepted.

Newington (London).—The tender of Messrs. J. F. Clarke and Sons, 49, Moorgate-street, amounting to £6,579, has been accepted for engineering work and electric lighting at the new public baths and wash-houses in course of erection in Manor-place, Walworth, for the parish of St. Mary's, Newington.

Egremont.—The Wallasey Urban District Council have alloted the contracts for electric lighting requisites as follows: British Insulated Wire Company, Limited, Prescot, Lancs., high and low tension concentric cables; Electric Construction Company, Limited, Wolverhampton, transformers; S Z. de Ferranti, Limited, 27. Charterhouse-square, London, E.C., engines, dynamos, etc. The Council do not make public the amounts of their accepted tenders

Colchester.—The result of the tenders for the electric lighting was given briefly last week. The firms tendering were:

	A.	B.	C.
Brush Company	£12,076 15 0	.. £12,442	.. £186 0 0
Christy Bros.	12,881 0 0	... 13,092	... 187 0 0
Electric Construction Company (accepted).	10,675 0 0	.. 10,940	... 257 10 0
Siemens Bros. and Co... Limited	11,477 0 0	... 11,708	... 375 0 0

A. 80 per cent. on completion, and balance after six months. B. Six months after completion. C. Loan of plant for military hospital The figures under this heading are calculated by the engineers on the assumption that 250 40-watt lamps are used three hours per day for, say, 30 weeks, equalling a demand of 6,300 units.

The following is from the particulars of requirements of the Council and conditions to be observed by the contractors: Each party tendering shall submit a complete scheme and tender for the whole of the plant, machinery, mains, feeders, street work, and everything that may be necessary (except buildings, foundations, and water). The total number of lamps assumed to be wired is 6,000; and although the distributing mains and feeders should be large enough for a maximum demand of 240 kilowatts, the plant and machinery need not at first have a larger working output than 150 kilowatts. Having regard to the compactness of the area to be lighted, and to the amount of private lighting already being carried on in Colchester, it is not thought desirable now to supply current for anything except 110-volt lamps; but it would be well, in view of probable extensions in the neighbourhood of the infantry barracks and in other directions, to take into account the possibility of using a higher pressure hereafter. Parties tendering must state what efficiency in pounds weight per hour of dry steam per Board of Trade unit they would be prepared to guarantee at the dynamo terminals during the last four hours of a 24 hours' test run As the War Office Authorities require current immediately for 250 40 watt lamps (100 volts) at the military hospital, parties tendering should state the terms upon which they would be prepared to lend a suitable temporary plant, and to run it for this purpose, until the permanent works are established. Payment will be made on the joint certificate of the borough engineer, acting for the Council, as follows: either (1) 80 per cent. as soon as the whole of the work has been satisfactorily completed, and the balance six months after; or (2) the whole of the moneys due to the contractors in one sum when the works have been run by them for six months.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,540.

Commercial Cable Company.—The Commercial Cable Company have declared a quarterly dividend of 1¾ per cent. on the capital stock.

Bromyard.—At the meeting of the District Council a draft agreement from the General Post Office for extension of the telegraph to Bishop's Froome was approved.

Digitized by Google

Ballymena (Ireland).—A meeting has been held and a deputation appointed to obtain, if possible, telephonic connection between Ballymena and Belfast with a local exchange.

Edinburgh.—Prof. Kennedy's report on the condition of the mains and plant has been published. Prof. Kennedy finds everything satisfactory. We hope to give the report next week.

Fulham (London) —The Vestry's Electric Lighting and Dust Destructor Committee have appointed Mr. W. R. Sayer as chairman and Mr. A. Cook as vice-chairman for the ensuing year.

Canterbury.—Mr R. Hammond, M.I C.E , has been appointed by the Town Council electrical engineer for the installation of the electric light, at a remuneration of 5 per cent. on the total cost of the works.

Cupar (Fife).—The Fife County Road Board have appointed a committee to examine and report in reference to the position of affairs with reference to the Board's contract with the Telephone Company.

Appointment Vacant.—The Electric Lighting Committee of South Shields want an assistant and draughtsman in the electrical engineer's office, at a salary of £100. Applications should be made to the Town Clerk.

Queen Anne Mansions.—The Queen Anne Mansions Electric Light and Heating Company, Limited, is to be absorbed in the newly-registered Queen Anne Residential Mansions and Hotel Company, Limited.

Swansea —The advisability of lighting the market by electricity is being seriously considered by the Corporation, and steps have been taken to ascertain the cost as compared with the existing system of lighting by gas.

Dundee.—The Works Committee have received a report by the burgh engineer upon the question of the twin-wire system of telephony and its probable introduction into Dundee, and deferred consideration of it to next meeting.

City of London Company.—The Board of the City of London Electric Lighting Company, Limited, have declared an interim dividend on the preference shares at the rate of 6 per cent. per annum for the half-year ending June 30.

Crosby.—At a meeting of the Urban District Council, the clerk produced a copy of the Bill in Parliament in reference to the electric lighting of the district, which he reported carried out the terms comprised in the provisional order.

York.—A meeting of the ratepayers has been held for the purpose of protesting against the adoption by the Corporation of an electric lighting system under municipal management, or the financing of any company with the ratepayers' money.

Halstead (Essex).—It has been reported to the Urban District Council that the meeting of the committee had not yet been held to consider the report on electric lighting, as the various members had not been able to fully digest the report on the matter.

Harrogate —At a meeting of the Town Council the electrical engineer was instructed to have the cable laid up Princes street and square to Victoria-avenue, in Albert-street, Market-place, and Cambridge-street, and to prepare a scheme for street-lighting.

Liverpool.—At the meeting of the Mersey Dock Board the proceedings of the Committee of Works, which contained a recommendation to accept a tender for an electric light installation for the new wool warehouse, Great Howard-street, were confirmed.

Carbon Contracts.—In the parliamentary return of contracts for articles of home manufacture made by Government departments last year with contractors outside the United Kingdom, the Admiralty is scheduled for £219 worth of carbons for electric lights.

Brazilian Submarine Telegraph Company.—The directors of the Brazilian Submarine Telegraph Company, Limited, have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ending March 31.

Lahore.—The Municipality are contemplating the lighting of Lahore by electricity. The city and station have been surveyed, and it is probable that a company will be formed to take the work in hand so soon as the Government can secure the necessary legislation.

Ripley.—This town has just been constituted an intermediate telephone call office. The Government having taken over the trunk lines, Ripley has been connected with Nottingham and Mansfield, and will doubtless receive further connections, including Derby.

Wells (Somerset).—The question of the adoption of the electric light was under consideration at a meeting of the Town Council. It was moved that Dr. Hopkinson be instructed to prepare plans and specifications for an installation of the electric light. The resolution was carried.

Ludlow.—At the Town Council meeting considerable correspondence was read on the question of the National Telephone Company and wires across the streets. Mr. T. Roberts moved, and Alderman Weyman seconded, that the wires be removed at once, and this was carried.

Stowmarket.—Through the enterprise of Messrs. Peddar and Prentice, who have erected works and wires in Ipswich-street and the Market-place at Stowmarket, the public and private residents there now have the opportunity of using the light in their business establishments and houses.

Paisley.—The Town Council have decided to appoint a resident electrical engineer at a salary of £200. Several offers of ground for the lighting station have been submitted to the Electric Lighting Committee, but they have decided to let the matter of site lie over till the engineer be appointed.

Eastern Extension, Australasia, and China Telegraph Company.—The directors have declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share, free of income tax, payable on the 15th prox. The share register will be closed from July 7 to July 14, both days inclusive.

Britannia Motor Company, Limited.—This is a new company formed to take part in the development of the horseless carriage industry, and to acquire the patent rights of the Britannia motor. The purchase price to be paid to the vendor is £50,000, payable as to £10,000 in cash and the balance in shares or cash.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending June 7 amounted to £1,152, as compared with £1,671 in the corresponding week of the previous year, being a decrease of £519. The comparison is, however, only formal, as the corresponding week last year was Whitsuntide.

Morecambe.—At a meeting of the District Council it was resolved that Mr. Thos. Parker, electrical engineer, Wolverhampton, be instructed to prepare the necessary plans, etc., for the proposed public electrical installation, at an estimated cost of £25,000, a site for the works having been provisionally secured.

Telegraph Clerks.—The annual conference in connection with the Postal Telegraph Clerks' Association has been opened at Exeter. Mr. Doyle (Dublin) moved a resolution protesting against the policy of reducing the male and adding to the female establishments of many of the large and small offices. The motion was carried.

Cardiff.—At the Town Council meeting a question arose as to the occasional failure of the electric light at the market in St. Mary-street, and eventually Mr. John Jenkins proposed, Mr. W. Evans seconded, and it was agreed, that a full report of the position should be prepared for presentation to the next meeting of the Council.

City and South London Railway.—The returns for the week ended June 7 were £930, compared with £904 for the corresponding period of last year, being an increase of £26. The total receipts for the half-year terminating as above were £21,465, compared with £21,437 in the same period of the preceding year, being an increase of £28.

Leamington.—At a meeting of the Town Council the report of the Watch and Lighting Committee was read, stating that the committee had asked Mr. Jones (manager of the Midland Electric Lighting Company) to give an estimate for lighting the parade with arc lamps of the pattern of one which they had recently inspected The report was adopted.

Rye —The report of the Technical Instruction Committee states that 13 students joined the electricity class. The students had made excellent attendances. On examination, Mr. Arnold King, reported that the result was creditable to the instructor, and that Mr. Milsom's paper was exceedingly good Three students in the electricity class were awarded certificates.

Birmingham.—The Public Works Committee have sat from 10 o'clock in the morning until nearly four in the afternoon to consider the recent proposals with respect to the renewal of the leases of the lines of the Central Tramways system to a syndicate. The committee determined to communicate nothing to the Press, but it is understood that they came to no decision on the matter.

Rotherhithe.—At the Vestry meeting, on the recommendation of the General Purposes Committee, the Vestry offered no objection, subject to a few minor conditions which had been accepted, to the intention of the London Electric Supply Corporation, Limited, to lay trunk mains in Rotherhithe New-road and Bush-road, in exercise of the powers conferred by their provisional order dated 1889.

Dewsbury (Yorks).—At a meeting of the Town Council it was decided to reduce the charge for electricity for heating and motive power. The electrical engineer was directed to lay mains for the supply of electricity to the Dewsbury and District Technical School at a cost of £540. The Town Council also decided to increase the salary of Mr. J. B. Mitchell, the Corporation electrical engineer, from £175 to £200.

Leeds.—The Tramways Committee have had under consideration the advisability of extending the tramway system in two or three different parts of the city. The feeling of the meeting appeared to be generally in favour of steps being taken to secure the necessary powers for this purpose, and it was resolved to hold a special meeting of the committee at an early date, when it is expected some definite recommendation will be made on the subject.

Whitehaven —The Electric Lighting Committee have reported to the Harbour Commissioners that they had received a letter from Mr. J. S. Brodie, borough engineer, intimating that the electric lights of the harbour would be altered and reduced. The committee agreed, with one dissentient, to allow the suggested alterations to be proceeded with Mr. Black, in moving the adoption of the report, remarked that the lighting had not been altogether satisfactory.

Simla.—*Indian Engineering* says that tenders for lighting the town hall and principal thoroughfares are being daily received by the Municipality, but it is scarcely expected that any will be accepted owing to the cost and to the little encouragement given to the idea by the tradespeople and private individuals. The engine-shed connected with the theatre is nearly completed, and the light will soon be used. This concern is entirely an enterprise of the Simla "A.D.C.," and the Municipality are not in any way responsible.

Digitized by Google

Dublin.—The electric tramway appears to be a great success so far as traffic is concerned. The whole of the rolling-stock has been in regular work, and the traffic is daily becoming larger. To meet this the company is already augmenting the rolling stock. Five motorcars will arrive during the week, and 15 more a little later. By the time horse show week comes round there will be 30 trains (60 carriages) of electrical cars at work. This will enable the company to despatch cars from the terminus at two-minute intervals.

Douglas.—Rapid progress is being made with the work of the southern electric tramway from Douglas Head to Port Soderick. It is expected by the promoters that the line will be completed by the early part of July. The date for the opening has been fixed for Saturday, July 4, and it is understood that Lord Kelvin has consented to visit the island for the purpose of inaugurating the electric tramway. It is stated that negotiations are in progress and are almost completed for the purpose of extending the tramway to a point quite close to Port Soderick. The line will be four or five miles in length.

Worcester.—The new Hope-Jones electric organ will shortly be completed in the cathedral One of the features of the electric apparatus is the provision of a "stop-switch," so that any combination of stops and couplers may be prepared in advance and brought into play at the moment desired. In order so far as possible to get expression, the great, swell, and choir keyboards will each be furnished with a "double-touch." The wind will be supplied by a new form of blowing-machine driven by an alternating current electric motor. The air will be drawn from the cathedral, compressed, and then stored in a portion of the crypt till required.

Milwaukee Electric Railway and Light Company.—Some 5,100,000dol. 5 per cent. 30 year consolidated mortgage gold bonds of this Company are to be put on the English market. This is part of a total issue of 7,000,000dol., of which 400,000dol. are in the hands of the public and 1,500,000dol. are retained to cover outstanding bonds. The Company in question is formed by the consolidation of various city railways and lighting companies, and owns and operates all the street railways in the city of Milwaukee. The price of issue is 102 per cent., or £204 per bond of 1,000dol., and the issuing firm is Messrs. J. P. Morgan and Co

Portsmouth.—In future the Portsmouth swimming-bath will be provided with a continuous supply of salt water, new electric motors having been erected for pumping purposes. The Electric Light Committee have decided to recommend the Town Council to purchase a new engine of 1,000 h.p. for the electric light station, and to borrow £10,000 with which to cover the cost of the engine and ot cable required for the extension of the mains. The engine itself is estimated to cost £6,200. The present boiler power will suffice to run this new engine, which will be adequate to meet the increasing wants of private consumers for a considerable time to come.

Tunbridge Wells.—The Town Council have decided to place incandescent electric lamps in Grove Hill-road in lieu of the existgas lamps. The town clerk has been instructed to apply to the lady of the manor for permission to lay mains across parts of the common. The tender of Messrs. Babcock and Wilcox for two large boilers at £543 each, a small one at £264, and a feed-water heater at £147 has been accepted, and tenders invited for the purchase of the present rectifier, to be replaced by a larger one The borough surveyor is preparing a report on the best site for stores and offices at the central station. The buildings are to be insured for £3,000 and the machinery for £4,000.

Simplex Tramway.—Under the title of the Simplex Electric Tramway Conduit Syndicate, Limited, a new company has been registered by T. T. Hull, 22, Chancery-lane, W.C., with a capital of £30,000 in £1 shares (5,000 A and 25,000 B), in order to acquire from J. B. Atherton a certain invention for improvements in the means of and appliances for distributing and collecting electricity for the propulsion of vehicles; to adopt an agreement with the said inventor, and to own and work tramways, railways, etc. The first directors, of whom there shall not be less than three nor more than seven, are E. K. Muspratt, A Adam, T. Snape, and J. B. Atherton. Remuneration, £150 each per annum.

A Lamp Supply Dispute.—At the Westminster County Court, before his Honour Judge Lumley Smith, Q.C., Messrs. Dodge and Fraser, Charing Cross, sued the London and Provincial Supply Corporation, Edgware-road, for £11. 10s. for two arc lamps and some repairs to dynamos on the defendants' premises. When fixed, the lamps did not work because the dynamos were not sufficiently powerful. The defence practically was that the plaintiffs ought to have told defendants this would be so. Plaintiffs' reply was that they understood the dynamos would have nothing else to do but to drive the lamps. The defendants had paid £5 into court, and his Honour ultimately gave judgment for £1. 7s. 6d. more.

Transformers.—The Consolidated Telephone Construction and Manufacturing Company, Limited, have devoted a portion of their extensive new works at Coventry to the construction of alternate-current transformers, and also main switchboards. Some new features are to be introduced to make the machine one of the most economical in the market, and the works manager is Mr. S. Sudworth, who was long associated with Mr. Gisbert Kapp. The company's manufacture will be distinguished by the registered trade mark and the words "C.T C. and Manufacturing Company." There is every possibility of the company having to build on the piece of freehold ground belonging to them, their present workshops being fully engaged.

Llanelly.—At a meeting of the Property Committee of the Borough Council an estimate was submitted by Mr. J. C. Howell for electrically lighting the principal streets of the town. The Surveyor said he had gone into the proposal with Mr. Howell, and the latter stated he would light up the additional streets suggested by the Council and include them in his scheme. The surveyor calculated that the saving to the town would be £400 or £500 per annum. The question was deferred. At a meeting of the Town Council a letter was read from the National Telephone Company, quoting £9 per annum on a five years' agreement for telephonic communication between the town hall and company's exchange. The terms were accepted.

Continental Metropolitan Tramways.—A provisional agreement has been entered into between the Continental Metropolitan Tramways Company, Limited, and the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston for the sale of the interest held by the former company in the Compagnie Générale Parisienne de Tramways, and also of the freehold property belonging to the company in Paris, for the sum of £392,800, together with the net profits of the company to June 30, 1896. The Board recommends, as a fair and equitable approximate scheme of distribution, to pay to the preference shareholders £5. 10s. for every £5 share, to the preferred ordinary shareholders £5 per share, to the ordinary shareholders £3 per share.

Coventry—At the Coventry County Court, before his Honour Judge Ingham, a petition for the winding-up of the Coventry Electrical Engineering Company, presented by Messrs. B. Verity and Sons, Birmingham, was called on. Mr. Masser, who appeared for the petitioning creditors, said he had received a notice from Mr. F. Thomas Jackson, a creditor, that he should oppose the order. Mr. Wilks represented Mr. S. T. Peirson, the liquidator of the company. He (Mr. Masser) had seen both Mr. Wilks and Mr. Maddocks (Mr. Jackson's solicitor), and an arrangement had been made that the matter should be adjourned till next court day. There was a receiver appointed for the debenture-holders and a voluntary liquidator, so that the estate would not be affected. His Honour granted the application.

Bristol.—The Electrical Committee having received applications from Mr. Harold Faraday Proctor, the electrical engineer, and Mr. John Rutherford Blaikie, the chief assistant engineer, for an increase of their salaries, recommend the Council to increase Mr. Proctor's salary to £400 per annum, increasing by annual increments of £25 to £500 per annum, it being understood that he will not seek to determine his engagement for three years from the time of the increase being granted; Mr. Blaikie is recommended for an increase of salary to £175 per annum, increasing to £200 per annum at the expiration of one year, on similar terms; and Mr. Thomas Henry Gait, the book-keeper in the office of the secretary to the electricity department, is recommended an increase to £120 per annum, rising by annual increments of £9 to £156 per annum.

Shoreditch (London).—The Vestry have amicably settled the dispute with the County of London and Brush Electric Lighting Company as to the rights of both parties in laying mains in certain streets originally bordering on the parish and now in the parish of St. Luke which is covered by the company's order. Messrs. Manlove, Alliott, and Co. have obtained a design from Messrs. Babcock, Wilcox, and Co. for special apparatus for blowing dust from the tubes of the boilers, involving an extra cost of £22 net on each of the six boilers The Vestry have, on the advice of the engineers, decided to purchase the apparatus. Forty-one applications have been received for the post of resident electrical engineer. The committee have selected six, and presented the name of one for appointment to the Vestry, but it was decided to instruct the committee to bring up the whole six to the Vestry.

Plymouth.—At the Borough Council meeting the Electric Lighting Committee recommended that with a view to prevent the necessity of reopening Old Town-street, Ebrington-street, and Ham-street after the street improvements now in progress were completed, application be made to the Local Government Board for authority to borrow the sum of £1,000, the cost of laying electric mains in those streets, and that the mains be laid prior to the completion of the street works. Mr. J. Willoughby, in moving the adoption of the recommendation, explained that the scheme of electric lighting had not been fully prepared yet, but in the judgment of the committee it was desirable to proceed with the laying of the mains in the streets mentioned, in order to avoid pulling up the thoroughfares again after the present improvements were completed. Mr. Jinkin seconded the proposition, which was carried.

Colchester.—The Electric Light Works Committee reported that schemes and tenders for establishing an installation for lighting certain portions of the borough by electricity had been received from the Brush Electrical Engineering Company, Limited, London; Messrs. Christy Bros., Chelmsford; the Electric Construction Company, Wolverhampton; and Messrs. Siemens Bros. and Co, Limited, Charlton. Messrs. John Fowler and Co. (Leeds), Limited, had written that as they were so busy they could not tender for execution of the works in reasonable time; and Messrs. Parsons and Co. had not sent in a tender. The tenders and conditions are given elsewhere in our columns. It was decided to accept the tender and scheme of the Electrical Construction Company, and to apply to the Local Government Board for sanction to the borrowing of £15,000 for the purposes of electric lighting.

Burnley.—The Town Council have approved of the appointment of Mr. W. R. Wright, of Manchester, as electrical engineer of the borough in place of Mr. Thursfield, resigned, at the salary of £200 per annum, to be increased to £250 per annum at the end of 12 months, providing his duties are carried out to the satisfaction of the Corporation. At the last meeting of the Council, Councillor Mercer (chairman of the Gas and Electric Lighting Committee)

Digitized by Google

moved that the Council authorise the committee to lay electric cables along Church-street and Ormerod-road of a sufficient capacity to supply 2,000 lights, at an estimated cost of £1,000. There were promises for 12 consumers, representing about 460 lamps. The income from those promises was estimated as follows: the gas bills at present were £180 per annum, the interest and sinking fund on the new main would be £60, cost of supplying the current £72, and they estimated a profit by the transaction of £48. The motion was carried.

London.—At the Court of Common Council, Mr. Brooke Hitching asked the chairman of the City Commission of Sewers whether, in view of the high charges made by the City of London Electric Lighting Company for the electric light in the City—viz, 8d. per Board of Trade unit as against 6d. and 5d. in other parts of London—the Commission had reserved to itself the right to purchase the undertaking from the company on equitable terms, or, if not, what notice would be required to be given to the company in the event of the Commission desiring to acquire the supply. Mr. B. Turner, the chairman, replied that the Commission had power to acquire the undertaking compulsorily at the end of 21 years on terms specified by the Act, so far as the public lighting was concerned. As regarded private lighting, the Commission could at the same period agree with the company for the acquisition of their powers, and failing an agreement, there were provisions for arbitration.

Lincoln.—At a meeting of the Special Electric Lighting Committee, letters from the Board of Trade were considered, and it was resolved "that application be made to the Board of Trade for a provisional order enabling the Corporation to put in force the provisions of the Electric Lighting Acts, 1882 and 1888." The committee recommended that advertisements be issued for applications for the appointment of electrical engineer, at a salary of £300 per annum. The committee had further resolved "that a provisional contract be entered into with Mr. C A. Harrison for the purchase of 1,750 square yards of land on Brayford side, at the price of 17s. per square yard, in order to provide for the generating station of the proposed electric lighting works." The committee further explained that Mr. Harrison had provisionally agreed to take £1 500 for the 1,750 square yards of land (about 17s. 1½d. per square yard) and the vendors' costs to be paid by the Corporation. The minutes have been confirmed by the Council.

London Tramways.—At Tuesday's meeting of the London County Council consideration was resumed of the report of the Highways Committee recommending that the County of London Tramways Syndicate should be informed that the Council, having given full consideration to the proposals of the syndicate as to arrangements being entered into between the Council and the syndicate for the immediate transfer to the Council of all the tramways in the county of London, were not prepared to enter into any such arrangements. The Hon. E Hubbard M.P., thought there was considerable feeling outside the Council with regard to the scheme, and it was well that it should be considered in all its bearings. He therefore moved as an amendment, "That the further consideration of the committee's recommendation be adjourned, and that the Finance Committee be instructed in the meantime to consider and report on the financial bearings of the syndicate's proposals." Mr. T. W. Williams seconded, and the amendment was carried by a majority of 19.

Yarmouth.—The Electric Lighting Committee have reported that additional applications had been received for 152 lamps, bringing up the total number of lamps to 8,143. The income last month was £133. 2s. 2d., and the expenditure £128. 17s. 8d., £4. 4s. 6d. being earned beyond cost of production, while repayment of capital, interest, rates and insurances amounted to £100 per month. On this report coming before the Town Council Alderman Wiltshire said one would have thought that the larger the number of consumers the larger would be the profits, but from the report it appeared that it was in an inverse ratio. The ordinary outlay for carrying on the work nearly balanced the income, while the ratepayers were left to pay £100 a month, or £1,200 a year, for the privilege of those persons who had the electric light. Alderman Martins replied that naturally in May, when the days were longest, the profits were materially reduced as compared with the winter months, and it was quite untrue that a loss of £1,200 a year was being incurred. At this time of the year business establishments used the light very little, but the applications from private houses were more numerous each month.

Electrical Copper Company, Limited.—This is a new company registered by Tatham and Lousada, 17, Old Broad-street, E.C., with a capital of £500,000, divided into 500,000 shares of £1 each, in order to carry into effect an agreement bearing date April 8, 1896, and made between Emilien Dumoulin and R. M. Moir and Co., on behalf of the Company, for the purchase of patents relating to industrial electrolysis of metals; to acquire any other patents for inventions capable of being used in the manufacture or treatment of copper or other metals; and to develop them in such manner as the Company shall see fit. The signatories are: H. M. Matheson, 3, Lombard street, E C.; C. A Fould, 35, Avenue Monceau, Paris; E. Dumoulin, 19 Rue Miromesnill, Paris; A. McKechnie, Ditton-road, Widnes; R M. Moir, 1, St Swithin's-lane, E.C; R. Lorimer, 1, St. Swithin's-lane, E.C; L S. Johnson, 197, Dalston lane; and the first directors are H. M. Matheson, A. Fould, W Jacks, Alex. McKechnie, Robert M. Moir, and E. Dumoulin, with a qualification of 400 shares and remuneration £2,000 per annum and a percentage of the profits, divisible. The registered office is 1, St. Swithin's-lane, E.C.

Malaga Electricity Company, Limited.—This Company has been registered by Ashurst, Morris, Crisp, and Co., 17, Throgmorton-avenue, E.C, with a capital of £57,000 divided into 10,000 ordinary shares of £5 each and 7,000 deferred shares of £1 each, in order to adopt and carry into effect an agreement expressed to be made between Zulueta and Co. and the Company, and to carry on the businesses of electricians, producers, and suppliers of electricity for light, heat, power, or otherwise; as manufacturers of and dealers in every description of electrical apparatus, and as electrical and general engineers, ironfounders, etc., at Malaga, Spain, or elsewhere. The signatories are: J. M. de Zulueta, 41, Moorgate-street, E C.; R. C. Wyatt, 41, Moorgate street, E.C.; A. Hill, 5, Tokenhouse-yard, E C.; F. S. Isaac, 22, Great Winchester-street, E.C.; A. Fowler, 6, Lombard-street, E.C.; L. Floersheim, 4, Bank-buildings, E.C; T. W. Bernard, Malaga, Spain; and the first directors—of whom there shall be not less than three nor more than four—are R C. Wyatt, G. von Chauvin, and A. Fowler with a qualification of 50 shares, and a remuneration 5 per cent. of the net profits, divisible, with a minimum £400 and maximum of £800 per annum.

Bury St. Edmunds.—The report of the Electric Lighting Committee, the substance of which has already been given in these columns, has come before the Town Council. The committee unanimously recommended that Mr. Medhurst's scheme be adopted and that he be appointed consulting engineer at a fixed fee of £1,000, with an additional £100 for clerk of the works. Mr. Ashton asked if the town clerk (Mr. C. E. Salmon) had considered the question as to the position of members of the Council who were shareholders in the gas company. Could they take part in the discussion and vote? The Town Clerk saw no reason to modify an opinion he had previously given in favour of their doing so. Mr. Turner moved, and Mr. C. Oliver seconded, the adoption of the report. Mr Ashton urged that Mr. Turner had not gone into the financial aspect of the question. The figures which had been submitted were purely an assumption. No guarantee was given that the suggested 2,500 lights would be taken. He disapproved of engaging a consulting engineer at such an exorbitant retaining fee, and moved that a poll of the ratepayers be taken on the electric lighting question. Mr. Lacy Scott seconded this. After a good deal of discussion this amendment was lost by 12 to 10, but ultimately further consideration of the question of adopting the scheme was adjourned for a month.

Aberdeen.—At the meeting of the Town Council, the Streets and Roads Committees recommended the Council to intimate to the National Telephone Company—"(1) That from and after June 30, 1896, the company will be required (*a*) to pay to the Council a sum of 10s. per annum in respect of every telephone pole erected or to be hereafter erected in any street or public lane within the city, such payment to be subject to revision by the Town Council at any time on giving the company six months' previous notice; and (*b*) to grant the Council a reduction of 25 per cent. per annum upon the charge made by the company for all telephone connections belonging to the Town Council, such reduction to take effect from the several dates at which the respective charges are payable; and (2) that in other respects the conditions relating to the erection of telephone poles and wires are to remain as at present." The report was adopted. A letter from Mr. R. Gordon Nicol, harbour engineer, as to electric lighting at the quays, was remitted to the Gas and Electric Lighting and Watching and Lighting Committees. The communication suggested an arrangement whereby the Council would light the foot pavements at the docks and the Harbour Commissioners would light the quay sides. It was mentioned that about 80,000 Board of Trade units would be required. An offer from the National Telephone Company, Limited, to establish communication between Invercannie Reservoir and the city at a yearly cost of £15 has been refused by the Water Committee

Keswick.—The Urban District Council having at a special meeting offered to purchase the electric lighting company's works for £2,000, the company replied with a counter proposal that the Council should hand over the working of their provisional order to the company on the latter agreeing to lay down new plant and mains immediately, in accordance with the joint recommendations of the Council's and the company's engineers, at a cost of from £2,500 to £3,000, and to pay the expenses of applying to the Board of Trade for the provisional order, and from time to time make such additions as may be required to this plant in order to meet the extending requirements of the district, and generally to put and keep the undertaking in satisfactory order; also, the Council should give the company at once the lighting of their street lamps and all other lighting under their control at a price of 6d. per unit or such other contract sum as may be agreed upon. At the end of 5½ years the company agree to sell the undertaking as a going concern, the price to be paid being calculated as follows: (*a*) £2,000, the price now offered by the Council; (*b*) the amount expended by the company on the provisional order and in alterations and additions as considered necessary by the engineers on commencing to work the order; (*c*) the amount subsequently spent by the company in providing for the extending requirements of the district; (*d*) a sum for goodwill which shall be 10 years' purchase on the amount of profit being realised by the company at the time of taking over by the Council over and above an amount sufficient to pay 5½ per cent. per annum upon the capital arrived at by adding (*a*) and (*b*) together. After a great deal of acrimonious discussion the matter was adjourned for three weeks.

London Extensions.—The Highways Committee of the London County Council have reported having received notice under Electric Lighting Acts and Orders from the Vestry of St Pancras, who desire to lay pipes for telephone wires from the Fitzroy-road electric lighting sub-station along Fitzroy-road and Kingstown-street, and from the Cobden sub-station along High-street to a

Digitized by Google

court adjoining. There appeared to the committee to be no objection to these pipes, which are for the Vestry's own use, being laid in the streets named. Also a notice from the St. James and Pall Mall Electric Light Company of intention to lay mains in Shaftesbury avenue subway, and in Wardour-street and Coventry street was reported unobjectionable A notice received from the House-to-House Electric Light Supply Company of intention to lay low-tension mains in Collingham-place, was recommended for the sanction of the Council, and also a notice of the same company to lay mains across Brompton road and to construct a transformer-box Other notices sanctioned were from the Charing Cross and Strand Electricity Supply Corporation to lay mains and construct street boxes in Oxford-street, Sutton street. Charing Cross-road, Cambridge-circus, Old Compton-street, Greek-street, Frith-street, Soho square and street, Dean-street, Carlisle-street, Little Chapel street, and to join the mains in Shaftesbury-avenue subway at three places; of the Kensington and Knightsbridge Electric Lighting Company of intention to lay mains in Burden-mews, Kensington; a notice given by the Westminster Electric Supply Corporation of intention to lay mains in Artillery-row and Howick-place; a notice from the Notting Hill Electric Lighting Company to lay mains across and along a part of Argyle road and along Stafford-terrace; a notice from the Metropolitan Electric Supply Company of intention to lay mains along the south side of St. John's Wood road (part) and the west side of Northwick-terrace; and, lastly, from the London Electric Supply Corporation of intention to lay mains in St. James's-place and Brook-street.

Bradford.—The work of the Corporation in the way of supplying electricity for lighting and other purposes has proved a success from the beginning, and an extension of the plant has become imperative. The present building could not contain all that was necessary, so it has been decided to erect another station. A site was purchased in Valley-road at a cost of £2 500, and on this a building is to be placed, the tenders for which amount to £11,588. The boilers, engines, dynamos, machinery, and plant to be fixed thereon will cost £17,593, thus bringing the total expenditure in connection with the new installation up to £31,368. The ceremony of laying the corner stones of the building has been performed, and the Mayor (Alderman W. W. Wood), in his remarks, claimed for the Corporation of Bradford the distinction of being the first municipal authority to set up an installation for electric lighting. It was seven years since the first station was opened, and they started with but three engines, three boilers, and 10 miles of cable. In the first year of the venture the financial statement showed a loss of only £1,250, which was decidedly encouraging. At the end of the second year it was £490, and during the third year they had a profit of £1,385 That was satisfactory, and he was pleased to say that from an estimate made it would appear that the profit during the year now closing would be something like £3,280. Their plant to day consisted of seven large boilers, 11 engines with over 2,100 h p., and 25 miles of cable. They had 402 customers, and their present supply covered an area of one square mile. When the new installation was completed, however, they would be able to cover nine square miles. It may be added that the works of the new station will be in one block, and will be divided into office buildings fronting Valley road, engine and dynamo room behind the offices, and a boiler-house running parallel with Lionel-street The ground floor will comprise the electrical engineer's office and general offices, opening out of a large tiled entrance-hall, with staircase leading up to the next floor. On the first floor will be a large committee-room, with windows overlooking the engine and dynamo room, and a storeroom and offices. The basement will be utilised for condensing plant The engine and dynamo room will be 85ft. long by 61ft wide and 28ft. high. It will provide accommodation for 12 engines and dynamos. It may be mentioned that the contractors have had to go some 10ft. below the surface of the ground to get a solid foundation. A travelling crane will run the whole length of the engine-house for moving any part of the plant. All the switches will be controllable from a platform which will run across one end of the engine-house. The plans for the building have been prepared by Mr. Thomas Barker, A.M.I.C.E., of Bradford, and the various contracts have been let as follows: masons' work, Messrs. J. Moulson and Sons, £7 350; joiner, Mr. Henry Thirkill, £810; ironwork, Messrs. Roberts and Co., £1,248; slaters, Messrs. Hill and Nelson, £267; plumber, Mr. R. Townend, £333; plasterer and concretor, Mr. Thomas Bolton, £414; painters' work, Mr. G. J. Walton, £116; wood-block flooring, Wood Block Flooring Company, £54; reservoir and tank, Messrs. J. Moulson and Sons, £890; gates and railings, Coalbrookdale Company, Limited, £123; and the condensing plant, Messrs. Cole, Marchent, and Morley.

Eccles.—At the Local Government Board enquiry, before Mr. G. W. Willcocks, into the application by the Town Council for power to borrow £20 000 for carrying out an electric lighting scheme and £11,348 for other works, Mr. G. W. Bailey, town clerk, represented the Corporation, and Mr. Overend Evans appeared for the Eccles Property Owners' Association, who opposed the electric lighting scheme; Alderman Spary opposed the grant of the order on behalf of a number of ratepayers; Mr. F. S. Hindshaw opposed on behalf of the Monton Green Ratepayers' Association; Mr. W. Broughton, a member of the Eccles Town Council, opposed as a deputation from a public meeting of the ratepayers; Mr. S. Hooley, Patricroft, for the Eccles Ratepayers' Association; and Mr. Alderman Mellor for the ratepayers of Patricoft. The Town Clerk, in support of the application for power to borrow £20,000 for electric light works, said the borough did not make its own gas, but obtained it from the Salford Corporation, and the charge at present was 2s. 4d. per 1,000ft. Therefore there was no question of setting up the works in opposition because of a dear supply of gas. Several companies, he said, had from time to time made application for powers to come into the borough and set up electric lighting works, and the local governing authority in order to prevent that had obtained provisional orders to carry out such works themselves. Some little time ago the Town Council, feeling that something ought to be done called in Dr. Hopkinson, who advised them that they could set up works and light the street lamps, etc, with electricity at practically the same rate as that paid to Salford for the supply of gas, and that, if that were done, within 25 years they would be able to redeem the cost of the works. A committee charged with the consideration of the scheme had ultimately adopted one designed by Mr. Clirehugh, which was on a different principle to that proposed by Dr. Hopkinson. This scheme was also opposed, and in order to find its cost tenders were asked for. The Manchester Edison Swan Company offered to carry out the whole of the works as regarded lighting for £13 792. Adding to that the tenders for buildings and other things the total was brought to £18,671, and that sum allowed 10 per cent. for contingencies. That showed that the work could be done for £200 less than Mr. Clirehugh's estimate. The scheme, he believed, was a moderate and reasonable one. Under it the Council proposed to light all the streets in the borough, and to adapt the present street lamps to incandescent electric lighting purposes. The Council also proposed to supply private consumers either for lighting or motive power. There would be a compulsory area, with separate wires, but the street-lighting throughout the borough would be all under one system. Mr. Alderman Kendall, chairman of the Electric Lighting Committee, gave evidence in favour of the scheme. Mr. Clirehugh, electrical engineer, in evidence, stated the works would have a capacity for lighting 750 public lamps of 20 c.p. and 3,750 private lamps of 16 c.p. A little over 21 miles of street cable would be laid. His estimate of the cost of the scheme was £18,971. The witness was cross-examined to show, amongst other matters, that his scheme differed entirely from that suggested for Eccles by Dr. Hopkinson. He said that Dr. Hopkinson's system was scarcely calculated to reach the smaller houses and there were many occupiers of small houses who now took the electric light. There were no accumulators in his scheme; he did not want them. Mr. Fawcus, of the Manchester Edison-Swan Company, gave evidence in support of the scheme, and the enquiry was adjourned.

Glasgow.—A discussion took place at the meeting of the Corporation as to the motor power to be used for the tramways. Treasurer Gray said that statements had appeared in regard to it, and he certainly expected that a report would have been laid on the table that day. He wanted to know if people might assume that the report which had already been submitted was complete, and that the committee had now travelled over the ground, and there would be a report at next meeting of Council, or, perhaps, in the middle of the month. Mr. Walter Paton stated that the matter was too important to be decided either in a week or a month even. It required very careful consideration in all its bearings. At present the Motor Committee were fully considering the matter, and he thought that within a reasonable time they would be able to give to the Council a report which he thought would be generally satisfactory. He did not think that there was any necessity for the committee to visit any other places to see anything more. Treasurer Gray gave notice to move at next meeting that, in view of the possible alteration of the tramway motors within the next few years, and after providing for all expenditure already incurred by the Town Council, the balance of the tramways surplus be applied first to a substantial reduction of the debt already incurred, and the balance be paid over by the Financial Committee to the Police Department in relief of the police rate. The Tramway Committee have received from the Simplex Electric Tramway Conduit Syndicate, Limited, drawings and estimates for the application of the conduit system of traction in Glasgow. According to the system, the conduit is formed under one of the track rails, a slot ⅜in wide giving access to the conduit, replacing the ordinary rail groove. A flexible conductor is supported at intervals of 30ft. on hook-shaped arms carried on insulators These insulators are placed in small chambers formed at the side of the conduit. The collectors consist of insulated conductors provided with U shaped contact-shoes carried in shanks, two collectors being attached to each car. The conductor is allowed to glide through these shoes, which pass over the supporting arms, the conductor being lifted during their passage and falling back again after the car has passed. The whole of the roadway can be constructed before any of the electrical appliances are placed in position, and when the line has been completed the insulators can be readily placed in the side hatchways by lifting the lids provided for that purpose. Assuming that the existing tramway is in good repair, the cost of the work is estimated at £3,000 per mile single line of track, or £6 000 per mile double line of track. In cases where the tramway rails are not in good repair the cost is estimated at £4,000 per mile of single line of tramway, or £8 000 per mile of double track. The company suggest, for demonstration, the Springburn route, and offer to carry out the whole work at their own expense. Should the installation give satisfaction, the Corporation will pay the cost of the work as per tender, but should the work not be satisfactory they will only pay for so much of the work and rolling-stock as they may be able to use for the purposes of an overhead installation, should they decide on its substitution for the conduit system. The reconstruction could be carried out without interruption of the existing traffic, and the permanent way provided would be

Digitized by Google

suitable for the overhead system. The necessary power could be supplied from the existing electric light station, so that the existing plant might be utilised during the day, when there is but little demand for light, for the purpose of working the tramways.

PROVISIONAL PATENTS, 1896.

JUNE 1.

11858. Improvements in portable electrically-driven pumps. James Compton Merryweather, Greenwich-road, Greenwich, London.

11891. Improvements in automatic grip clutch for straining wires for telegraphic, telephonic, and like or similar purposes. William Phillipps 76, Chancery-lane, London.

11894. Improved means for opening and closing doors by electricity. Solomon Cambie, 76, Chancery-lane, London.

11903. An improved frictional electric machine. Heinrich Sobersky, 6, Lord-street, Liverpool.

JUNE 2.

11973. An improved movable platform for electric lamp-posts. Albert Dalolry, 1, Grove-place, Broadway, Ealing.

11981. Improvements in and connected with electrical indicating apparatus. James Grieve Lorrain, Norfolk House, Norfolk-street London. (Mathias Pfatischer. Edward S Hosmer, and Harold Binney, United States)

11985. Improvements in and connected with electric arc lamps. Charles Edward Harold Edman, 23, Coleman-street, London.

11999. In or relating to marine telegraphy. Richard Joseph Crowley, 58, Lincoln's-inn-fields, London.

12028. Improvements in and relating to caps for electric incandescent lamps. Reuben James Bott, 11, Southampton-buildings, Chancery lane. London.

12039 Improvements in transmitting electrical impulses and signals and in apparatus therefor. Guglielmo Marconi, 24, Southampton-buildings Chancery-lane, London.

JUNE 3.

12070. Improvements in transmission dynamometers. William Ernest Dalby, Engineering Laboratory, Cambridge University.

12149. Improvements in electrolytic apparatus. Trevenen James Holland, 6, Bream's-buildings, Chancery-lane, London.

JUNE 4

12178. Tamplin's new electric bicycle lamp. Archibald Hubert Tamplin, 29 St. George-street, Leicester.

12183. An improved method of electric traction by means of the conduit system. William Cope, 127, Bristol-road Birmingham. (Complete specification.)

12187. A new or improved shade and reflector for electrical and other lighting. George William Pridmore, Thomas John Sturgeon, and Edwin Yorke, 2 Broad-street buildings, London.

12227. An improvement in secondary voltaic batteries. Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London

12244. New or improved electrical lighting apparatus. Ernest Oldenbourg, 115, Cannon-street, London.

12248. Improvements in or connected with automatic switches for controlling electric lamps. William James Davy, 40, Chancery-lane, London.

12249. Improvements in electric arc lamps. William James Davy, 40, Chancery-lane, London.

12250 Improved plates for secondary galvanic batteries and a method of producing the same. Carl Marschner, 45, Southampton-buildings, Chancery-lane, London

12259. Improvements in or connected with dynamo-electric machines. Valerè Alfred Fynn, 47, Lincoln's inn fields, London.

12266. Improvements in electricity meters. William Morris Mordey, 46, Lincoln's-inn-fields, London.

JUNE 5.

12275. Self-lighting and part driving of vehicles by electricity. Michael Twomey, 42, Pope's-quay, Cork. (Michael Twomey, ———.)

12312. A new or improved apparatus for electrically smelting metals and for other purposes. John Laskey Dobell, 57, Chancery-lane, London.

12329. Improvements in electrical switches. Gustav Binswanger, 73 St. Stephen's-road, Upton Park, London

12330. Improvements in electrical switches. George Wilkinson, 73, St. Stephen's-road, Upton Park, London.

12344. Method of indicating at a telephone station whether the telephone lines are engaged or not. Emil Naglo, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12345. Automatic apparatus for the working of telephone stations. Emil Naglo, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12360. Improvements in or connected with variable gearing applicable to wheeled vehicles driven by electricity, petroleum, steam, or other motive power. Frank Frederick Wellington and Edwin Percival Allam, 33, Chancery-lane, London.

12362. Improvements in and applicable to electrical accumulators. Joseph Tabrar, 57, Crampton-street, Newington Butts, London.

JUNE 6.

12398. A flexible crystal covering for electrical conductors. Lewis Davis 36, Spital-square, Norton Folgate, London.

SPECIFICATIONS PUBLISHED.

1892.

2329*. Bleaching by electrolysis. Imray. (Montgomery.) (Amended specification)

1895.

9372. Electric oven Middleton and Neale.

9433 Electrically signalling on locomotives. Burn and Tate.

9882. Electric conduits Safety Tread Syndicate, Limited, and others.

10155. Telephone systems Freudenberg.

11085. Arc lamps Andrews.

11951 Telephonic exchange system Berditschewsky (called Apostoloff)

12417. Secondary battery plates. Weise

12690. Electrically-propelled vehicles. Brault and Jeantaud.

13619. Electric railways and tramways. Wetter. (Elektrizitats Aktien Gesellschaft vorm. Schuckert and Co)

23250. Electric accumulators. Schneider.

1896.

2501 Conveying electricity to railway cars. Krotz and others.

3627 Telephones. Russell and others

5171 Arc lamps, electroliers, etc. Baker.

5951 Electric cars. Devonshire. (Bassett.)

6576. Microphones. Hardegen.

7794. Incandescent electric lamp shade holders. Hellyer.

7881. Electric current transformers Devonshire. (Moody).

7884. Electric current power systems Devonshire. (Berg.)

NOTES.

Institution of Electrical Engineers.—We may remind our readers that the annual conversazione of the Institution takes place on the 25th inst. at the Institution of Painters in Watercolours.

Hartlepool Tramways.—In consequence of extreme pressure on our space, we are compelled to hold over the description of the Hartlepool tramways which we hoped to have given in this week's issue.

Book Received.—We have to acknowledge the receipt from Oskar Leiner, of Leipzig, of Mr. Arthur Wilke's book on the mutual influence of telephones, which we hope to notice at greater length shortly.

New Anglo-German Cable.—The German Reichstag has passed the second reading of the supplementary credit of 1,288,000 marks for laying a fourth telegraph cable between Germany and England.

Foyers Aluminium Works.—Last week the water of the river was diverted into the tunnel of the British Aluminium Company at Foyers. It will be remembered that the whole of the works were described in our columns a short time ago.

Personal. — Mr. A. P. Lundberg, who has been dangerously ill from erysipelas, the result of a bicycle accident in April last, is now out of all danger, and it is hoped that in a month's time he will be quite convalescent and able to resume business.

Motorcart Competition.—It is announced that the Brussels paper *L'Industrie* proposes to have a motorcart competition somewhat after the fashion, though on different lines, to that of the *Engineer*. Details and conditions are promised to be given shortly.

Physical Society.—The following are the papers to be read at the Physical Society on June 26: (1) "Admittance and Impedance," by F. Bedell; (2) "On the Properties of a Body of Negative Resistance," by S. P. Thompson; (3) "On Bare Wire Resistances," by H. F. Burstall.

Electrolysis.—Mr. D. Tommasi has proposod a new arrangement of plates for electrolytic purposes, and communicated his proposal to the Paris Académie des Sciences. The essential part of the arrangement is to have two anodes, and one cathode between them. This is circular in form and only dips about halfway into the solution. It is mounted on a shaft and revolves slowly between rubbers.

Telegraphs in Borneo.—It is stated that the land line across British North Borneo, which has been in course of construction for some time past, is expected to be completed by the middle of September. The two opposite working parties hope to meet this month. The construction of the line to Sandakan will place the capital of British North Borneo in direct telegraphic communication with England *viâ* Labuan and Singapore.

Rural Telegraphs.—In the course of his reply to a deputation which waited upon him last week on the subject of telegraphic communications, Mr. Walpole made the interesting statement that on the average not a week passed in which the Post Office did not open five new offices in different parts of the country. It is also to be arranged that telegrams in rural districts should be delivered by cycle instead of by man and horse. The effect of this is that the charge will be 4d. instead of 1s.—which is good. It is, however, to be hoped that a certain amount of discretion will be allowed as to sending out telegrams by bicycle over muddy cross-country roads in the winter time.

Telegraphs in Siam.—It is considered probable by *Indian Engineering* that when Mongsin comes under French administration more will be heard of the project to link up the Indo-Burma telegraph system with the Tonkin wires. At present Kengtung is the terminus of the telegraph from Burma. The French wire stretches from Hanoi up the Red River to Mong Low Kai, and thence turns in eastward to Mong Lai. In the Mekong Valley the French have also run the telegraph to Keng-Kan, and have possibly extended it to Luang Prabang. The best route for the connected line to take would be from Kengtung to Mong Lai, about 230 miles.

Cambridge to Glasgow.—It is part of the duty of the Cambridge Public Orator to put into classically beautiful Latin things that the Latins never dreamed of, much more named, and when he has to write a complimentary address to a modern man of science he has some work to do it. But our own schoolboy, to whom, as having had less time to forget, we refer such matters, absolutely refuses to translate "septentrionum regionem accuratius indicasti" in Dr. Sandys's address to Lord Kelvin on the occasion of his jubilee by "invented an improved form of mariner's compass." Yet, if it does not mean that, what in the world does it refer to?

Illuminated Rifles.—The tales of tiger hunting by electric light, the invention of which is a kind of agreeable exercise for the overworked brain of the Anglo-Indian, appear to be accepted quite seriously by *L'Etincelle Electrique*, and, what is worse, that journal says the "Prussian" army want to play the same trick on the enemy that the Anglo-Indian does on the tiger, and have actually gone so far as to fix small electric lamps—why not the ordinary bullseye lanterns?—on their rifles. Our contemporary anticipates that these will not prove of much use against men armed with Lebel rifles having a range two-thirds of a mile.

The Motorcart Bill.—The Bill for the legalisation of motorcarts has passed the House of Lords. It has, of course, still to go through the more serious ordeal of the Commons, and considering the position of business in the Lower House it is to be hoped that there will be no very serious opposition to it there. For although the motor carriage may not be going to do just at present all that some of its advocates expect, so many arrangements have been made in view of the early removal of the existing legislative restrictions that even a delay of a few months in the passing of the Bill would cause great disappointment, inconvenience, and loss.

Lightning.—It is a popular notion (though, of course, there is no real warrant for it) that lightning never strikes twice in the same place. The *Pall Mall Gazette*, however, reports that last Sunday during a severe thunderstorm at Glasslough, a village in Ireland, the tower of the parish church was struck by lightning, and a heavy stone pinnacle fell to the ground. A few moments afterwards a second flash entered the building, where evening service was being held, and several worshippers sustained slight shocks and burns. It is added that "the panic among the congregation was so great that the service was suspended." We should think it was. They may call that sort of thing panic in Ireland, but hereabouts it would be considered justifiable precaution, pending the conclusion of the storm and the examination of what was wrong with the lightning conductor.

An Australian Difficulty.—It is in the ordinary course for the consulting engineer to consider whether he

Digitized by Google

can or cannot get condensing water for his engines; but what would he do if he could not get water for his boilers at all? Mr. G. E. Addenbrooke's answer to this conundrum is, "Use oil-engines." At any rate, that is what he recommended to the Westralian Electric Light and Supply Company, Limited, which has carried out the electric lighting of Coolgardie. Of course, in a place where there is any amount of gold and no water, one's ideas of economy require to be entirely reconsidered. However, the Westralian Company, having bored deep enough, have struck water in quantity which does not play the Australian joke of coming up hopelessly salt. So this interesting example of electric lighting under difficulties is to be superseded by a common steam plant.

Society of Arts.—The conversazione of the Society of Arts took place on Wednesday night at the South Kensington Museum. There were a very large number of guests, who were received by Major-General Sir John Donnelly, K.C.B., the chairman, supported by members of the council and the secretary, Sir Henry Trueman Wood. Amongst those present were Sir Douglas Galton, Sir Henry Roscoe, Mr. Preece, Sir Frederick Bramwell, Mr. Alexander Siemens, Sir Guildford Molesworth, Lord Belhaven and Stenton, Dr. and Mrs. Schofield, Prof. and Miss Hughes, Prof. Unwin, Dr. and Miss Routh, Mr. Webb, Sir John and Miss Fisher, and Captain Abney. There was a promenade concert in the north court by the band of the Royal Artillery and in the textile court by the Red band, and there was a vocal and instrumental concert in the lecture theatre.

Meteorological Society.—The last meeting of the Royal Meteorological Society for the present session took place on Wednesday, when Mr. H. Harries read a paper on "Arctic Hail and Thunderstorms," in which he showed that the accepted opinion that hail and thunderstorms are almost, if not quite, unknown in the Arctic regions is incorrect. He had examined 100 logs of vessels which had visited the Arctic regions, and found that out of that number no fewer than two-thirds showed that hail was experienced at some time or other. Thunderstorms were not so frequent as hail, but they have been observed in seven months out of the twelve, the month of greatest frequency being August. Mr. Harries thinks the breeding place of thunderstorms in these high latitudes is in the neighbourhood of Barents Sea. A paper by Mr. J. E. Cullum on the "Climatology of Valentia Island" was also read.

Night Signals at Sea.—Some experiments have been carried out at Portsmouth with a new night-signalling apparatus, the invention of a Captain Sellner, an officer in the Austrian navy. The signalling is carried out with two lanterns, on either of which five different arrangements of red and white lights can be shown, the two together being able to show no less than 30 different combinations. Electric lights are used for the lanterns, and though separate batteries are used for the lights and for the signalling apparatus by which the lights are changed and obscured at will, eventually it is intended that one dynamo shall be so arranged as to supply all the current required. A check on signals sent by the apparatus is obtained by a device by which the message sent is automatically printed by the working of the signals. It was found that no difficulty was experienced in reading the signals at a distance of six miles and more.

Flying Machines.—It will be remembered that Prof. Langley in the United States recently made a flying machine which, contrary to the custom of flying machines, really flew. The trials were made as privately as is possible for such a thing to be done, and very little was known about the machine or the motor used. Mr. H. S. Maxim now writes to the *Times* to say that Prof. Langley has been working on the same lines as himself. "In regard to the future of flying machines, I would say that if machines are to be made on the aeroplane system small ones will be found to work much better than large ones. Should Prof. Langley increase the size of his machine sufficiently to be enabled to carry one man he will find that the building material, which is steel and aluminium, is not relatively so strong for a large machine as for a small one, and a large machine in order to lift has to be propelled at a much higher speed than a small one." That is so. The biggest birds cannot fly, and, if the geological record is to be depended on, never could.

Metropolitan Railway. — Experimental trains having been run on the Metropolitan Railway at the only time when they could be run without disturbing the traffic—namely, late at night—someone jumped to the conclusion that the company was about to adopt electric traction. Several paragraphs on the subject having appeared in London and provincial papers Mr. A. B. Garside, the assistant manager of the company, was interviewed on the subject and at once contradicted the statement. Mr. Garside said that his company, in conjunction with others, had long been studying the matter of electric locomotion, but the experiments that had taken place were not in connection with that matter, but simply to ascertain the effects of curves and gradients on certain portions of the line. Even if the author of the report had no idea of what would be necessary before a trial of electric traction could be made, it is curious that it should not have occurred to him that an electric train would hardly be pulled by a steam locomotive.

City and South London Railway Bill.—Outside the ordinary and natural difficulties of construction and compensation to interests affected by it, the City and South London Railway seems to have more than its fair share of obstacles to overcome. The preserving intact all the empty and unused City churches at one time threatened to seriously endanger the Bill for the extension to Finsbury-pavement and Islington. This difficulty was got over before the Bill left committee, but no sooner did it come before the House than there was a motion to recommit it in order to use it as a pretext for fighting the question of whether the law should not be altered to allow a vestry to levy rates on unoccupied property. It may be good parliamentary tactics, but it hardly seems a straightforward course to attempt to get an important and far reaching precedent established by working it in under the form of an amendment to a private Bill, and it is certainly unfair to the enterprise affected. In this case, however, the House of Commons promptly stopped the attempt by a majority of 122.

High-Voltage Power Transmission.—The Westinghouse Company, in connection with the Telluride Power Transmission Company, of which Mr. L. L. Nunn is general manager, is carrying on some experiments in power transmission at high voltage at Telluride, in the United States. According to the New York *Electrical Engineer*, Mr. Nunn has been supplied with converters amounting in all to about 200 h.p. capacity, and suitable for transforming from 3,000 to any desired higher voltage up to 60,000 volts, and these converters are used as raising and lowering transformers in transmitting about 100 h.p. over an ordinary iron telephone wire a distance of about two and a half miles to operate a stamp mill, the iron wire constituting the line costing only 35dol. (£7). When Mr. Nunn first proposed this transmission of two and a half miles

Digitized by Google

some years ago, using direct-current transmission, the estimate made for copper was in the neighbourhood of 65,000dol. (£13,000). This transmission plant has been run at various voltages, from 15,000 to 60,000 volts inclusive, and during snowy weather at about 35,000 volts.

Electric Waves.—Some experiments made by Cole's method on the refractive index and reflective power of water and alcohol for electric waves have been described in the *Annalen der Physik und Chemie*, from which it would appear that for waves of 300cm. to 600cm. length the refractive index for water was 8·95 and for alcohol 5·20, which is in agreement with the figures obtained by other observers. With waves of 5cm. length the two Fresnel formulæ give the same value of the refractive index from the observed reflective power; for water it was 8·8 and for alcohol 3·2; for alcohol the refractive index for long waves is appreciably greater than for short ones. It also appears that waves 5cm. long pass only with great difficulty through even very thin layers of water of 0·04cm., although long electric waves readily pass through the water and both traverse with ease wood, paper, rubber, and many other opaque materials. With these waves reflection is total from metals when the oscillations are at right angles to the plane of incidence and only partial when they are parallel to this plane. It will be seen that all these values are exceedingly high compared with those for the longest known light waves.

Acetylene.—At the convention of the National Electric Light Association in New York a paper was read by Mr. Ferguson on "The Commercial Value of Acetylene Gas," which makes out anything but a glowing prospect for that illuminant. The manufacture of calcium carbide at generating stations as a means of keeping the machinery employed during periods of light load it would not pay commercially, and would be bad policy from a business point of view. Acetylene manufactured from carbide does not give so much light by 28 per cent. as is obtained by the direct use in incandescent lamps of the electric energy necessary to produce the carbide, while comparison with the electric arc is out of the question. The final conclusion is that, "in the light of our present knowledge, and upon the basis of the estimated cost of production of the calcium carbide, acetylene gas should not drive the incandescent and arc lamp from the lighting field, neither should it make such inroads on the electric lighting business as to materially affect the earnings of existing central-station companies, for, after all, acetylene is a gas and burns with a naked flame, and the use of incandescent and arc lamps has steadily increased year by year, not because of their cheapness, but because of their infinite superiority as illuminants over any gas flame yet developed."

The Metric System.—At the Congress of Chambers of Commerce of the Empire last Saturday the final resolution on the paper related to the metric system. Mr. J. X. Perrault (of Montreal) moved: "Whereas the British system of weights and measures, which vary constantly in every part of the British Empire, is a source of constant annoyance, loss of time, and a formidable obstacle to local, Imperial, and foreign trade; and whereas the metric system has now been universally recognised as the most perfect decimal system, and generally adopted by nations of both continents, with the exception of the British Empire and the United States of America; be it resolved, that the metric system of weights and measures be adopted without further delay by the several Governments of the Empire, the yard being extended to the metre, the quart to the litre, and the two pounds weight to the kilogramme." This was seconded by Colonel Harding (Leeds), and, after discussion, was agreed to, but a further resolution dealing with a decimal currency was adjourned till the next congress. It is easier for a congress to pass a resolution than to get it adopted, however mandatory may be the terms used. But seriously, if and when the "several Governments of the Empire" comply with the commands of the Congress of Chambers of Commerce, would it not be better to do the whole thing at one stroke? The confusion and trouble of the change will be bad enough without arranging that as soon as we have adjusted our prices to the new weights and measures, we shall have to go through the whole process again in order to fit the prices to the new money.

Ayrton's Magnetic Tester. — At the Central Technical College conversazione last Friday an interesting exhibit, which was practically absolutely new to most of the visitors, was Prof. Ayrton and Mr. Mather's apparatus for testing the magnetic properties of iron. As with the exception of the Royal Society's soirée two nights before this has never before been publicly shown, and has only been very briefly described by its authors, rather more space may be given to it than can be afforded in our account of the conversazione. The instrument at first sight looks like a very small dynamo with abnormally developed pole-pieces and an exceedingly small air-gap, and as such might be easily passed by as a mere model without its practical purpose being guessed at. On closer examination the above description is seen to be substantially correct, with the exception that there is no core inside the coil of the field magnet. The sample to be tested is inserted here and completes the magnetic circuit through the pole-pieces and armature. This latter is run at a constant speed (something over 1,100 revolutions per minute), and the number of the coils is so adjusted that 10 times the magnetising current, as measured by an ammeter in the exciting circuit, gives H, while the E.M.F. in the armature circuit, read by a high resistance or an electrostatic voltmeter, requires only to be multiplied by 10,000 to give the value of B in the sample tested. It will be seen, therefore, that by varying the exciting current a curve can be plotted straight away. The instrument has been in use for some time in the laboratories of the institute, and is looked upon there with much favour. Several hysteresis curves plotted by its means were shown, and in one (of what appeared a rather bad sample of iron) the corrected values were also plotted in red. For a large portion of the lozenge curve the two traces were practically superposed, and at no point was there more than a very slight distance between them.

Institution of Naval Architects.—Last week the Institution of Naval Architects, after meeting at Hamburg, adjourned, by invitation of the German Emperor, to Berlin. On the first day the Emperor was present at the discussion, and throughout great attention appears to have been shown to the members of the institution. Mr. Dietrich, Constructor-in-Chief of the Imperial German Navy, in the course of a paper on the development in design and construction of German men-of-war, said the German vessels carried every athwartship bulkhead above the water-line without any door in it, while communication from one engine-room to the other was established only over the protective deck above water, or might be carried on below by telegraphs and speaking-tubes. In this England might with advantage copy Germany, and, again, in employing electricity as much as possible instead of steam. The German Admiralty found that the only way to get rid of the heat from numerous steam-pipes was to do away with them. By the use of electricity the conducting wire took the place of the steam-pipe, and the ships were rendered more healthy as well as safer in action. All

Digitized by Google

new German warships have electricity as the motive power for ventilating fans, turning gear of gun turrets, ammunition hoists, coaling winches, and such purposes. Some discussion followed on the subject. At a subsequent meeting there was a further discussion on the watertight-door question, which at one time threatened to become heated. It is probably necessary to have lived some time on a man-of-war to be able to enter into the feelings of some members on the subject. When several of them had liberated their minds on the subject, a paper by Mr. Eichenradt on the use of electricity on board ships was taken. The members, of course, visited the Berlin Exhibition and several works. There were complimentary dinners and luncheons, and the Emperor held a special reception in honour of the institution.

Dyemaking. — The Chicago *Electrical Journal* says "that some of the colouring matters hitherto only produced by strictly chemical processes can also be manufactured by electrolytic processes, and it seems extremely likely that the near future will see a very large number of such substances being made by electro-chemical means. Towards the end of last year it was discovered that certain orange colouring matters can be obtained by electricity, and now we understand that they are being made on a commercial scale at Basle, in Switzerland. It seems that by reducing the yellow alkaline condensation products of p-nitroluene sulphonic acid in an alkaline solution by means of the electric current, the yellow colouring matters are converted into orange dyestuffs. A mercury cathode is preferably employed, as the production then proceeds at a lower temperature. The best strength of current is 5-15 amperes per square decimetre of cathode area. About 10 kilos of p-nitroluene sodium sulphonate are condensed in the usual manner in an aqueous solution with 30 kilos of soda lye of 30deg. B. After dilution with 70 litres of water, the whole is reduced at 45deg. C. in an electrolytic cell with a mercury cathode until a sample is spotted on paper which shows a red spot free from yellow. The solution is then neutralised and the dye-stuff salted out. After filtering and drying, it forms a dark-brown powder easily soluble in water, with a yellowish-red colour, and in concentrated sulphuric acid with a dark violet-blue colour. It dyes unmordanted cotton orange from a neutral or alkaline bath, fast to air, chlorine and acids. If this new process stands the test of time, and succeeds in producing dyes which possess as good qualities as the same substances manufactured by chemical processes, and at the same time possess commercial advantages, we may anticipate that a new and important field will be opened up."

An Irrigation Plant.—The *Journal Officiel* of the Egyptian Government gives some particulars of the opening by the Khedive, on May 18, of an electric installation at Korachieh which presents some points of interest. A difficulty in the way of all agricultural machinery is that a large plant must be provided capable of dealing with the crop when it is ready and which, after getting through its work, has to stand idle for the greater part of the year. Unless, therefore, it can be turned to some other purpose, the capital expense becomes exceedingly heavy in proportion to the work done. The Commission of the Egyptian Domain had at Korachieh, near Tantah, a cotton-cleaning plant run by a steam-engine of 120 h.p. This works only from the middle of September to the end of December, and stands idle for nearly three-quarters of the year. To one of the engineers of the Commission, Mr. Souter, was due the idea of utilising this engine for the purpose of providing the power necessary for pumping the water for irrigating 5,200 feddans (about 5,726 acres) of agricultural land. This has been successfully carried out, and the nine 12-h.p. engines and pumps formerly in use for irrigation purposes have now been replaced by three pumps driven by motors with energy derived from the cotton works engine. The generator is a four-pole continuous-current dynamo separately excited, and each of the pumps is driven by a two-pole motor. The makers are Messrs. Hillairet-Huguet, of Paris. The distances of the pumps from the cotton works are about $2\frac{3}{4}$ miles, five miles, and two miles respectively. The following was the cost of the electrical part of the work, the figures being in Egyptian pounds, which, however, only differ by a penny or two from sterling money. For 33,500 metres of copper wire, insulators, switches, poles, and the ordinary accessories, £E1,030; dynamos and motors, £E1,025; pumps, belts, etc., £E770; buildings, £E750. This, with the addition of a telephone and items for Custom House charges and cost of erection, brings the total up to £E4,280. It is estimated that as a result of this expenditure there will be an annual saving in coal, wages, etc., of about £E660, but the portable engines used for driving the pumps were old ones and might have been replaced by engines of a newer type, in which case the annual saving would have been £E390 in favour of the electric working. No further details beyond those given above are available as to the character of the transmission line, and the voltage is nowhere stated.

Electric Locomotives.—The General Electric Company have shipped from the Schenectady works the last of the three great electric locomotives for the operation of all trains on the main line of the Baltimore and Ohio Railroad. These locomotives will handle the entire freight and passenger traffic of the Baltimore and Ohio road passing in and out of Baltimore from the North, through the Belt Line tunnel, which passes under the city. Each locomotive weighs 96 tons and is capable of developing 1,500 h.p. The first was put into service in August last and the second in December, since which date they have been handling the entire freight traffic of the Baltimore and Ohio road through the tunnel without accident of any kind. No limit of speed has yet been reached with these engines. Eighty miles an hour has been attained, at least an American contemporary says so, but short-distance records of this character are never looked upon in railway circles as very reliable, and from what follows it will be seen that it is quite probable that the speed is a computed and not a measured one. As soon as the third locomotive reaches Baltimore it will be put into work, and the three engines will then undertake the passenger service as well as the freight traffic, and the present coke-burning engines used with the passenger trains will be shut off before entering the tunnel. Particulars of the working of the tunnel with these locomotives were given some time back in the New York *Electrical Review*. From these it appears that the smallness of the leakage in the overhead construction has exceeded all expectations, considering the dampness in the tunnel. The working voltage is 630. It has been found that there is quite a knack in starting the train, and the present operators say they can start a train without jerks better than with the steam locomotive. The pull of the locomotive was measured with a dynamometer car, from which the draw-bar pull per ton of train on the 0·8 per cent. grade was calculated, and was found to be 22lb., which, after subtracting the grade pull of 16lb., left a difference of 6lb. as the train resistance per ton. The draw-bar pull per ampere was found to be 28·6lb. An electrician on the locomotive is not necessary, as the present locomotive engineers operate it very successfully. Acceleration was measured by taking two-second readings and

Digitized by Google

plotting the curve; a train of 985 tons could be accelerated up to a speed of about 12 miles an hour in one minute; probably steam locomotives could not equal this. A speed of 61 miles an hour up grade has been reached, and this is considered to be equivalent to 70 or 80 miles on a level. With a 300 or 400 ton train a speed of 40 to 45 miles an hour can be made.

The Pacific Cable.—At the meeting of the Congress of Chambers of Commerce of the Empire last Friday the proposed Pacific cable was discussed. Mr. J. X. Perrault, of Montreal, moved that, "Whereas an extension of direct telegraphic communication throughout the Empire would considerably facilitate and increase the commercial relations of the mother country and her several colonies, and be also a source of security and strength in maintaining uninterrupted hourly communication in time of war, and whereas the Atlantic and Canadian systems now extending to the Pacific coast offer special advantages over all other routes to establish direct telegraphic communication between the mother country and Australia through uninterrupted British territory, be it resolved that, as an alternate and direct line of communication, a cable should be laid between Australia and Canada without further delay, the Imperial and Colonial Governments directly interested being respectfully requested to offer such inducements to the constructing company as may determine the laying of the Pacific cable at the earliest possible moment." The Hon. Robert Reid seconded the resolution, and Sir Mackenzie Bowell suggested that the words "to the constructing company" should be omitted. There were those who held that a cable of the character intended to be exclusively British should be constructed, owned, worked, and managed by the different Governments, and the reason for that proposition must be apparent to any one who would give the subject a moment's consideration. Although the cable might be laid by a company, those who invested their money in an enterprise of that kind must expect to receive some return for it, and if it was placed in the hands of promoters they must anticipate making a certain amount of money out of it. If, however, it was constructed by Governments exclusively, whether by the aid of the Imperial Government or by the Colonial Governments alone, they would only have to supply telegraphy to the commercial world at the cheapest possible rate, raising a sufficient amount of money to pay the interest on the money invested. There would be no promoters' fees to pay, there would be no striving after a large amount of receipts. He was one of those who believed that while the old saying about trade following the flag was literally true, at the present day it was as necessary to have telegraphic communication between the different parts of the Empire as it was to have ships to do the business. The resolution was carried unanimously with the alteration suggested by Sir Mackenzie Bowell. Mr. Plummer (Newcastle and Gateshead) moved, "That, so far as possible, it is most important that inter-Imperial postal and telegraph routes should be established between this country and the Colonies, as well as between the Colonies themselves, without such routes passing through other countries." Mr. Coates (Ottawa) seconded the resolution, and it was carried unanimously.

Central Technical College.—On Friday last a conversazione was given at the Central Technical College of the City and Guilds of London Institute in Exhibition-road, South Kensington. There was a very large number of guests. The Lord Chancellor (chairman of the council) and Lady Halsbury held a reception in the library, and among those present were noticed Sir Frederick Abel (chairman of the Executive Committee), Sir Frederick Bramwell, Sir Owen Roberts, Mr. John Watney (hon. secretary), and Profs. W. C. Unwin, Armstrong, Ayrton, Henrici, Kipping, Moody, and others directly connected with the college, while the City Guilds, which have so honourably contributed to its support, were represented by masters of several civic companies, Mr. Sheriff and Mrs. Cooper, and Mr. Sheriff Pound. Sir Owen Roberts, Sir H. and Lady Knight, Sir Walter Prideaux, Sir William and Lady Flower, Sir Douglas Galton, Sir Arthur and Lady Arnold, Sir John and Lady Donnelly, Mr. Crookes, Dr. Frankland, Profs. Kennedy, Tilden, Lockyer, Herring, Reinold, and Gladstone, Dr. Hopkinson, Dr. Garnett, and Prof. Silvanus Thompson were also there and very many others whom the writer did not see or did not recognise. During the evening the National Hungarian Band played in the main hall, and a concert arranged by Dr. Lapworth and other members of the chemistry department was given in the lecture theatre. As to the serious part of the business, any attempt to describe within reasonable limits of space what was to be seen would degenerate into a mere catalogue of apparatus and instruments. There were, as a matter of fact, something between 70 and 80 rooms of them, and professors and students ready to explain anything to anybody. In the basement were to be seen the boilers, engines, and dynamos, with the measuring and testing instruments relating to them. Somewhere down there we noticed the "injector" with which Messrs. Beeton, Taylor and Barr made their investigations into the effects of varying the form of alternating-current curves. It was not, however, in action. In the mathematical and physical departments were several new apparatus which have recently been described at the Physical Society. Prof. Ayrton and Mr. Mather's magnetic testing apparatus requires some description, and must form the subject of a separate note. In one of the mathematics rooms was a fine collection of instruments, including planimeters and integrators, harmonic analysers, integraphs, and so on. A lady asked if she was expected to understand all these, and was told that it was quite easy. There were about five different calculating machines ready to multiply for visitors to any reasonable extent, not to mention slide rules in various forms. It was consoling, however, to the mere fallible human being to see that with at least one of the machines it was possible for a clumsy person to get a wrong answer. The Röntgen photography appears to continue as much the rage as ever. Prof. Ayrton had something like half a dozen fluorescent screens and tubes going in a dark room, and as soon as the visitors found out where it was they simply crowded it. There was another room devoted to the same subject upstairs. A noticeable exhibit, also upstairs, was the apparatus with which Mrs. Ayrton has made her investigations into the fall of potential across the arc. The image of the arc and the mirror spots of the instruments are reflected back on to a screen in such a way that, as Mrs. Ayrton explained, "you can do the whole of the work without moving from your chair." Higher up there was an exhibition of art wood-carving done by past and present students. At the extreme top of the building was the crystallography room. Few reached it, but those ladies who did were much interested in the (model) gems. On the other hand, the anorthic crystals appeared quite at a discount. There were specimens of naphthalene derivatives prepared in a research of Mr. Ripping's, which is still in progress. This conversazione was the first time since very early days that the classrooms and laboratories of the college have been open to inspection in working order, and the occasion was an exceedingly interesting one.

MUNICIPAL ELECTRICAL ASSOCIATION.

(Continued from page 661.)

On Friday morning a business meeting was held at the Royal United Service Institution, and the following programme for the ensuing year was arranged:

Place of meeting for 1897.—Manchester.
President.—Mr. C. H. Wordingham, city electrical engineer, Manchester.
Vice-Presidents.—Mr. Victor A. H. McCowen, city electrical engineer, Belfast; and Mr. F. Newington, city electrical engineer, Edinburgh.
Committee.—Mr. Arthur Wright, past-president, Brighton; Mr. Wm. Arnot, past vice-president, Glasgow; Mr. A. H. Gibbings, Bradford; Mr. A. B. Mountain, Huddersfield; Mr. John H. Rider, Plymouth; Mr. T. P. Wilmshurst, Halifax.
Hon. Treasurer.—Mr. G. H. Cottam, Hampstead.
Hon. Secretary.—Mr. A. B. Mountain, Huddersfield.

It was unanimously resolved to present to Mr. Wm. L. Madgen, who has been acting as hon. secretary during the period of organisation and the first convention, the best thanks of the members for the invaluable help he has rendered in the formation and organisation of the association, and, as a record of their appreciation, the resolution is to be suitably engrossed and presented to him, with a bronze to be selected by himself.

Visit to Brighton.

No more agreeable and pleasant manner of ending the first convention could have been suggested than that of a visit to Brighton, whose electric lighting undertaking is under the command of the association's first president. The party were received at the Royal Pavilion by the Mayor (Alderman Blaker) and the Electric Lighting Committee of the Corporation, headed by the chairman, Councillor Stafford, J.P. All the members and visitors having assembled, they were photographed in a group on the east lawn. An adjournment was then made to the music-room, where the chair was taken by the Mayor. He was supported by the president and the members of the Electric Lighting Committee.

The MAYOR said it was his first duty, as representing the citizens of Brighton, to extend to them a very cordial welcome to the town. They would be very pleased to show them any works belonging to the Corporation which might interest them, and he hoped they would be able to stay the night so that they might see the light in the streets. With regard to the undertaking itself, he freely and candidly admitted that when the consideration of the matter was before the Corporation he did his very best to oppose it. He felt, and many others felt with him, that they were rushing into the unknown and might be incurring any amount of difficulties hereafter, but he was glad now to say that he had made a mistake. Their success was well known. They had spent about £150,000—or rather they had invested that amount—and he had no doubt from what he had seen that it was a good and a proper step for the inhabitants, by their representatives, to take in acquiring the electricity works themselves. They all acknowledged their indebtedness to the municipal electrical engineers and those who worked with them throughout the country, but they were not satisfied. They wanted to be carried by electricity, they wanted their food cooked by electricity, and they wanted even to fly by electricity. He concluded by again according them, on behalf of the citizens of Brighton, a most hearty welcome.

Councillor STAFFORD, on behalf of the Electric Lighting Committee, supplemented the Mayor's remarks. He said he was not an expert; he was a business man, and he should speak with reference to the commercial undertaking, as he regarded it in Brighton. Their success had been owing to their progressive policy. They had gone in for catering for the million, so to speak, rather than for the rich residents of Brighton. They had done their utmost to cater for the ratepayers who backed their Bill. Those of the ratepayers who used the current were benefited by the roduction in price, making electricity almost as cheap as any illuminant, or quite as cheap if they considered the saving in the wear of decorations. And the other class of ratepayers, though not assisting them by consuming the current, were benefited by reduction of rates, for last year the electricity undertaking saved a penny rate. The committee were ready to lay down mains where there was any probability of their paying, and he might say that the large houses were not so much benefit to them as shops and even small houses in thickly-populated districts, while the hotels were almost their best customers. He congratulated the association on their choice of a president, and joined with the Mayor in heartily welcoming them to Brighton.

Extensions to Outlying Districts.

Mr. A. H. GIBBINGS, electrical engineer, Bradford, read an abstract of the following paper on this subject:

Some three months ago, when asked by your committee to contribute one of the papers for discussion at the first convention of our association, the writer was much interested in the consideration of this subject. It is one which is becoming of increasing importance day by day, both to the municipal electrical engineer and the municipality, and to each it presents many interesting and many novel features. The extension of electricity supply from the central station to the outlying districts of a township has, however, already become in very many cases a matter of urgency, and while there always exist distinctive features in each case, there are also many points common to all which may be considered with advantage. Considerable difference of opinion exists as to the comparative economy of the various methods of supply; but this is a point upon which, for the purposes of the present paper, we can well afford to agree to differ, because it does not in any way affect the main question now before us. The municipal electrical engineer is face to face with the problem of extending the supply in the most economical and satisfactory way; the town councillor has before him the demand for the supply from the members of his constituency in outlying districts. Let us deal with both sides of the question from a general point of view. The chief considerations apply equally to all municipal electric light undertakings, irrespective of the particular system adopted in each borough.

There are at present in operation in England, Scotland, Ireland, and Wales about 51 municipal electric light stations, and those towns which have already obtained their provisional order, and have electricity works in course of construction, number about 20, making a total of 71 municipal electric light enterprises in the United Kingdom. Of the above number 19 have been in operation over three years, and it is generally after the lapse of this period that the necessity to extend the hitherto confined area begins to be felt. The word "necessity" is used advisedly, because it accurately describes the situation, both as regards the majority of the ratepayers and the business itself as a trading concern. The period of three years is really too long to delay the actual extension of the mains; the writer is inclined to curtail the time by 12 months, for reasons which will be put forward towards the end of this paper.

Having decided that the necessity for extension will surely arise, *nolens volens*, the points to be considered may be stated to be—(1) the cost of extending the supply; (2) the effect on the cost of production and revenue; (3) the advisability of extensions.

The Cost of Extending the Supply.—Priority is given to this particular phase of the subject, as, very naturally, it is the one upon which great stress is laid by electric light committees. It is often made the most important point, other aspects being considered secondary matters. Unfortunately, too, comparisons are only made with what has been the cost of supply in the central portion of the town. It can be shown, however, that such comparisons are incorrect, and that too great prominence is often given to the initial cost of extensions. The cost of extending the supply is affected by—(1) the method of laying cables; (2) the characteristics of the suburban or outlying district; (3) the extent and class of demand. By the method of laying is meant the system which in economy and efficiency is found to be most satisfactory when the character of the suburban district, and the extent and class of the demand, are taken into account. It is, therefore, essentially a question to be decided for each district separately, by each town individually, considered with reference to the general system of electrical supply adopted by each. But, after all this has been said and emphasised, it is also universally true that many of those items which form so large a part of the cost of laying mains in the centre of a town are very much modified, if not entirely eliminated, in connection with the extension of mains in the suburbs. Such items are: (1) the reinstatement of footways and road paving; (2) the necessity for making ample provision for future demands by laying additional conduits; (3) the avoidance of obstacles under the footways and roads. It is not necessary to enlarge upon the very different effect which these items have upon the cost of laying the mains in the central and outer districts respectively. One or two illustrations will suffice. Attention is drawn to them merely because in some towns the difference will no doubt be very

Digitized by Google

much greater than in others. In the matter of reinstatements, the cost of different paving is given in the following table for towns differing in size, position, and configuration.

COST OF REINSTATEMENTS PER YARD RUN. (About 2ft. wide.)

Town.	York stone, including new stone.	Patent asphalte.	Compo. Stone.	Granite setts and concrete.
City of London	3s. 8d.	Footway 6s. 4d. / Roadway 11s....	—	7s. 6d.
Hove (Sussex)	1s. 6d.	3s.	3s.	--
Hull	2s. 7d.	—	—	6s. 5d.
Bradford	3s. 8d.	—	—	8s. 4d.

From this table it will be seen that the cost of reinstatements varies considerably, but the figures also indicate the width and depth of trench made, and from this it may be inferred that more or less provision has had to be made at the time of opening for future extensions. A proportion, therefore, of the cost of reinstatement of conduits and cables laid really represents capital already spent for an extended supply, capital lying idle until a revenue is derived from outside. The method of laying cables in the central area is very naturally determined by the conditions referred to above, but where such conditions do not exist, as in the outer districts, other methods of laying mains may be adopted, by which the cost may be still further reduced when compared with that involved by the original method. For instance, in the case of a low-tension supply the first necessity of heavy feeders and distributing mains laid in expensive conduits might be substituted in the outer areas by armoured cables laid directly in the ground, or, in the case of high-tension, by a system of banked transformers substituted by direct supply to each consumer. The characteristics of the outlying districts and the probable extent and class of demand, considered in relation to the cost of extending the mains, may now be considered. Let us take these two items together, as the one depends very largely upon the other. In the very broadest sense these, of course, are really the determining factors with regard to the size and length of mains to be laid down. It can be shown that this may be ascertained as a very much more definite quantity than is possible when estimating the probable demand in the central area. The outlying districts may be scattered and thinly populated, or they may be the reverse. There are usually both instances in most towns. Scattered districts are likely to be composed of large houses, rich residential neighbourhoods, and unpaved streets ; in the second case, main streets leave the town, with a continuous run on each side of terrace houses, occasional shops, with a surrounding neighbourhood of side streets and residences.

Now, the very first advantage we have in considering the possibilities of supply in the above cases (and the consequent size of cables ultimately required) is the knowledge that, while the probable demand from business quarters is a greatly varying quantity, utterly impossible to forecast, in residential districts it may be comparatively easily gauged. Some shops in the centre of a town are let and relet in the course of two or three years, one tenant requiring eight or ten lights, another requiring no light at all, and a third demanding a supply for 40 or 50. This is only a typical instance of what occurs over and over again in the course of 12 months. Under such circumstances there is no basis upon which to work, and hence we have to be prepared for any demand. But it is different with residential houses. The annual rental is a safe guide, as the following table of rentals and corresponding gas bills, real and not imaginary, will show. The gas is 2s. 3d. per 1,000 cubic feet, and the length of the street is about three-quarters of a mile.

Description of property.	Annual rental.	Number of houses, shops, etc.	Aggregate amount of annual gas bills.	Average annual amount per house, etc.
			£ s. d.	£ s. d.
Shops only ...	£20 to £40	19	76 3 0	4 0 0
Do. ...	£40 to £50	2	11 18 0	5 19 0
Do. ...	£50 to £100	6	58 19 4	9 16 6
Houses only...	£20 to £40	24	91 8 4	3 16 2
Do. ...	£40 to £50	19	147 16 2	7 15 7
Do. ...	£50 to £100	50	506 0 2	10 2 4
Do. ..	£100 to £150	2	27 18 10	13 19 5
Houses and shops combined	£20 to £40	11	49 9 2	2 4 11
	£40 to £50	17	146 1 4	8 11 10
	£50 to £100	20	243 7 0	12 3 4
	£100 to £150	4	92 16 10	23 4 2
Hotels	£100 to £350	3	233 10 6	77 16 10
Theatres	£1,000	1	333 14 8	333 14 8

Each single account represented in the above summary showed, upon comparison, very little variation from one year to another, and therefore it should not be a difficult matter to estimate the maximum number of electric lamps likely to be required for many years in such a district. The table, of course, represents only one main street, but the illustration will serve for branch streets and abutting property. Hence, we can see how the characteristics and probable demand enable us to make accurate calculations, and so economise in the method of laying and the capacity of the mains. Now, it will readily be admitted that the points just dealt with are the very points which form the basis of comparison in estimating the relative value of one system over another. But, whatever the system, there can be no doubt that the cost of extending the mains can be very considerably reduced when compared with the cost of laying mains in the centre of the town.

The Effects on the Cost of Production and on the Revenue.—Supplying outlying districts with electricity appears at first sight simply to entail increasing the output at the central station, with a corresponding increase in the revenue. And the cost of production appears to be affected just in the same way as if the additional supply occurred in the central portion of the town. In reality, however, the effect on the cost and revenue is of a much more important nature, and it is this feature which gives the supply a relatively higher value. This is due entirely to the fact that the number of units consumed for a given maximum demand is very much greater in the outlying districts than for a corresponding demand in the centre of the town. In other words, private houses, small shops, etc., use the light for a greater number of hours than business offices and large shops within the central area. While the latter use a large number of lamps for a few hours a day, the former use only a few lamps, but burn them a considerable time. And so it comes about that the number of lamps installed cannot be made a direct and all-sufficient basis of calculation in estimating the probable revenue. We must also take into consideration the number of hours the lamps burn. Considerable assistance may be obtained in arriving at an approximately correct estimate if we know what is the general figure in lamp-hours per day in several towns. In the following towns the number of units sold per average 8-c.p. lamp connected at the end of 1895 is found to be as follows :

Town.	Units sold per lamp.
Hull	11·23
Aberdeen	12·85
Hanley	16·80
Leicester	17·46
Blackpool	18·05
Bradford	18·68
Manchester	20·60
Bristol	22·02

If we take these figures and reduce them to the number of hours per day during which the total number of lamps would be burning in order to produce the above annual ouput in units, we get the following result :

Town.	Watts per 8-c.p lamp per day.	Average hours per day per 8-c.p. lamp would be burning.
Hull	30	1 hour 0 minutes.
Aberdeen	35	1 hour 2 minutes.
Hanley	46	1 hour 32 minutes.
Leicester	48	1 hour 36 minutes.
Blackpool	49	1 hour 38 minutes.
Bradford	51	1 hour 42 minutes.
Manchester	56	1 hour 52 minutes.
Bristol	60	2 hours 0 minutes.

The average of these representative figures is 1 hour 33 minutes ; or, in other words, the total capacity of the station is being used for only 1 hour 33 minutes per day in producing the satisfactory results to which these towns have attained. There can be no question that the time during which the major portion of the revenue is earned is for the first two or three hours after dusk. A reference to any central-station load curve will prove this, and, further, that more than 50 per cent. of the lamps connected are not in use at all for six months of the year. Now, this is just where the private consumer comes in and fills the gaps. His lamps, although adding to the plant capacity at the station, also increase the average earning capacity, and in the proportion estimated in the following instance. If we assume that an equal supply is demanded by the central and the outer districts respectively, then, of course, the plant capacity at the station would be double that required for the central portion only ; and if both classes of the demand were like that in the central area, the whole plant would still be earning its entire revenue in 1½ hours per day. But it may be safely assumed that 75 per cent. of the demand in the outlying districts will be continued from 7 to 11 p.m. on an average throughout the year, or, say, for fully four hours longer than the central portion. Now, 75 per cent. of half the maximum demand is equivalent to a little above one-third of the maximum demand continued fully for four hours, and this is, of course, equal to the full demand continuing for 1¾ hours. It will at once be seen from this simplification of the matter that the earning capacity of the plant has been increased from 1 hour 33 minutes to 3 hours

Digitized by Google

18 minutes, or more than twofold; or, in other words, the number of units sold are doubled for the same maximum demand. But what is true of the whole is true of a part, and hence the earning value of every 8-c.p. lamp connected in the outlying districts is three times as great as that of a corresponding burner in the central portion of the town. In addition to this relatively higher value of the residential supply as compared with the shop and office supply, the former would be required very largely on Sundays, thus giving an additional 52 days' consumption on the year. It would also form a better load on holidays, and during the winter months from 6 a.m. to 8 a.m. For all these reasons such a supply is eminently desirable.

Having determined the relative value of the demand from the residential districts, it is an easy step to ascertain the effect on the cost of production and on the revenue. The cost of production is made up of the actual cost of generation—viz., coal, oil, etc.—and the standing charges—viz., wages, salaries, repairs and maintenance, interest on capital, sinking fund, depreciation, rent, rates, taxes, etc. Taking the average of a score of central stations, the charge per unit is about as follows: generating cost, 1d.; standing charges, 3·5d.—total, 4·5d.

With a slightly increased efficiency of the generating plant that portion of the cost is likely to be slightly reduced, but it may be taken, nevertheless, to remain practically the same per unit—namely, 1d. But, assuming an equal demand in both central and outlying districts, the number of units sold for the same standing charges is doubled, and therefore this item of the cost would decrease in the same ratio—that is to say, the 3·5d. per unit would become 1·75d. and the total cost per unit 2·75d. instead of 4·5d. This at once opens up the possibility of a substantial reduction in the price: a reduced price would probably attract new customers, and thus, step by step, we might ultimately arrive at a universal adoption of the light. We can even imagine the demand from the outlying districts being twice as much as that in the central area (a very common feature of gas suppply) and in that case a general price of 3d. per unit would then be most remunerative. This, at least, seems to be certain, that every lamp connected in the residential districts has the effect of helping to reduce the standing charges in the ratio of 2 to 1, as far as its own consumption is concerned.

With the foregoing explanation it is easy to see what is the effect on the revenue. The price to the consumer remaining the same, 5d., 6d., or 7d., the revenue or net profit would be increased by exactly the same amount as the standing charges would be decreased. In the example given the standing charges would be decreased by 1·75d. per unit, and by itself this amount would form a very considerable net profit even if the average charge per unit was only 4½d. The average price obtained, however, by most municipalities is more than 4½d., and at that price a net profit is made of from 3 to 5 per cent. Of course, the object of the municipalisation of these undertakings is to supply electricity at as low a price per unit as is consistent with fairly paying expenses and providing for contingencies, but the price will never descend to a popular figure while the supply is confined to the central area. The possibility of a reduction commences, however, as soon as the many-hours private householder has the opportunity of using the light. Such a reduction should take place naturally and gradually as the demand in the other districts increases, and when we remember that every lamp supplied there brings in the same revenue as three in the central portion, the effect on the profits of the department would not be long in becoming apparent.

The Advisability of Extensions.—The writer has endeavoured to show that, as a question of finance, extensions would probably be very remunerative; but there is, of course, still another factor to be taken into consideration, and that is the rate at which consumers will avail themselves of the new light in these districts. The same uncertainty existed not so many years ago when the public supply of electricity from a central station was first commenced. At that time, too, there were many other problematical features which do not exist to-day; there were obstacles, prejudices, conflicting interests, which have since been overcome. And the responsibility of such an enterprise as a wholly new undertaking was beyond all comparison greater than any question which electric lighting committees are now called upon to consider. The venture then was almost entirely speculative, owing to the absence of fundamental data, and in many instances (notably Bradford, the first municipal central-station supply) the business was started to keep out a private company. The success which has been met with, however, has been beyond expectation, and this fact is in clear evidence by the present 51 corporation electricity supply undertakings, and by the efforts of several other municipalities to buy up the rights which they have so recently allowed to fall into the hands of private companies. These rights and undertakings will undoubtedly have to be paid for very heavily before the corporations become possessed of them. Yet in the face of these practical experiences we still hear of towns and parishes such as York, Barrow, Lambeth, etc., which are fighting the same old battles and traversing the same dreary ground about the establishment of electricity works as the pioneer municipalities encountered many years ago.

We might reasonably infer, I think, from what has been the experience in regard to the central area—viz., that while it was difficult to forecast the probable demand, yet the result has been a very general adoption of the electric light—so with regard to the outlying districts, the result should be an equally steadily-increasing demand. As to the probability of this deduction being verified, I am able to give an instance in point. In 1893 the Bradford Electricity Committee canvassed, among other districts, the street to which I referred in the second section of the paper, and for which I have given the representative annual gas bills. This canvass was a personal house-to-house enquiry, but not a single individual would give a guarantee to take a supply. The price per unit was the same as at present—namely, 5d. In June, 1894, the committee made a further effort by means of a circular letter. Very few replied, and only one individual definitely promised his patronage. At the beginning of this year I brought the question again before the attention of the committee, and advised them to lay the mains as a matter of speculation, and they so far conceded as to grant the extension for three-quarters of a mile. Of course, in face of what I may call the negative results of the canvass, this was a great and bold step to takes. When this was known to the wiring firms, they on their own account immediately canvassed the street, but in one month only succeeded in getting three applications, with a total of 70 8-c.p. lamps. A month later we commenced to lay the mains, the wiring firms in the meantime continuing to solicit orders, but without success, the general excuse being a desire to wait until the mains were laid. So the mains were started with three promised customers. Before the entire length was laid, however, the number had increased to 10, demanding a maximum supply of 210 8-c.p. lamps; and as an instance of what a little judicious speculation will do, the number at the end of May, or one month after the mains had been completed, was 16, with 260 8-c.p. lamps connected. Now, I think this instance is a very good argument against relying to any extent upon canvassing. Of course the streets with which to commence the extension have to be selected with discretion, but once started, a supply will soon be demanded over the entire area of the borough.

I mentioned in the first part of this paper that I considered two years a sufficient period after the establishment of the electricity works to initiate a scheme for the supply to the outlying districts. My reasons for naming two years are twofold. First, at the end of that period the supply will probably have become generally known and appreciated, and the financial position of the undertaking is generally sound and good. Secondly, I think it very desirable that the inner and outer districts should then grow simultaneously. The load curve would thus be improved, and the probable future needs of the town would be more readily gauged and satisfactorily provided for than would be the case if the extension were long delayed.

To sum up the whole matter: To me it appears that at the present time the great object for municipalities to aim at is the reduction of the price at which electricity can be supplied. I contend, and have endeavoured in this paper to justify my contention, that this object is attainable. Not only so, but that it may be attained in a most satisfactory manner by developing the enterprise. Like the railway companies of old, I have every confidence that we should go forward—certainly not in a headlong spirit of reckless extension, but, on the other hand, with an unhesitating and deliberate movement of advance.

Discussion.

The **President** said the association had happened to come to a town where the policy advocated by the Lighting Committee amply bore out the conclusions arrived at in the paper. In Brighton there was hardly a house that was not within a quarter of a mile of some electricity distributing main. The committee saw the necessity of pushing these mains out to districts long before promises for taking the current were obtained. They found, as Mr. Gibbings stated, that it was no use canvassing districts before they put the mains down; the mains themselves were the best canvassers. He agreed with Mr. Gibbings as to the importance of the private-house load to the central station. When the central part of the town had finished its work the inhabitants migrated to the outside, and it was this demand later in the evening that was so useful in lessening the cost of supply. However, it seemed to him putting the case too high to say that a lamp in a private house was worth three times the value of a lamp in a shop. They found as the result of their practice at Brighton that the number of hours a private-house consumer used his light was practically the same as the shop—namely, two hours a day throughout the year, but owing to its being at a later period, it was better than the shop. On the other hand, the shop lights were very regular, and the private-house lights very irregular.

Mr. Giles said that in Blackburn they found it impossible to continue their low-tension mains in such straggling districts as theirs. They used the high-tension alternating supply. The consumers living a long way from the mains had agreed to pay 6 per cent. of the cost of laying the mains to them; the payment was limited to 16 years. There was also a reduced interest if anyone else came on their service.

Digitized by Google

Mr. Higginbottom said they had seriously considered this subject in Manchester, and even now were applying for parliamentary powers whereby in one direction they would have to go nine miles and in another seven miles, and they would be bound to cover these areas in two years. He did not agree with the policy of the last speaker as to charging a rent upon the mains taken into a new district for the supply of any particular house. It was unfair to those ratepayers who required it, because in the event of a loss on the undertaking it would come upon the rates, and those ratepayers who paid extra for the light would also have to pay their share of the deficit. In Manchester wherever a customer had asked them to go they had gone.

Mr. Dixon was also an advocate for laying down the cable and letting it advertise itself. In Bradford they had adopted the opposite policy, and sent out circulars, and it had all amounted to nothing, but directly they laid down the cable the applications came in faster than they could deal with them.

Mr. Mountain remarked that the lamps from the residential district did not bring in so much as the shops, and yet the residential portion was the only portion at the present time which was paying.

Mr. Manville contended that the question was best solved by using a low-tension current for the central district, but let it be an alternating one and not a continuous one.

Mr. Boot (Tunbridge Wells) said that in the town he represented the mains had been extended very rapidly after the first working. For some time they had more residential houses taking the light than shops, and they could not have supplied these lamps unless they had adopted the policy of extension wherever the demand arose.

Alderman Norman said that in Cheltenham their customers were very much scattered, but the Corporation advocated the policy of extending the cable wherever required free of cost to the consumer.

Mr. Wordingham, on being asked by the president how they were going to deal with this question in Manchester, said he really did not know. It seemed to him necessary to get the work done by one station or as few stations as possible. To get that on one station for a very large district implied some form of high tension. He disagreed with Mr. Manville that they should do it with alternating currents, and argued strongly in favour of the continuous current. His view was that they should put down a station which should supply the immediate district at as high a volt pressure as possible—that was, 400 volts. For the immediate neighbourhood of the station they should use the five-wire system; for the residential district they should use the three-wire system for 200 volts; and for the outside places they should use high-tension—say, at 3,000 volts continuous—to be transformed up from the 400 volts and then transformed down again on the distributing mains. Their system must be, he thought, a portion low tension and a portion high.

Mr. Quin (Blackpool) gave some interesting figures as to the cost and details both as to Blackpool and also Brighton, which town he has lately left.

REPLY TO DISCUSSION.

Mr. Gibbings, in reply, said he was sorry to see that the discussion had degenerated into a question of system. With regard to the system he could only say that that must be left to each engineer to work out according to his requirements. As regards the cost, when he said it would be likely to be less in the outlying district, he did not mean to infer that it was necessary to lay cables half a mile or three-quarters of a mile directly a customer applied for it.

Votes of Thanks

On the proposition of Mr. RIDER, seconded by Mr. ARNOT, a hearty vote of thanks was passed to the Mayor and Corporation of Brighton for the loan of the Pavilion, and for their cordial reception.

By the generosity of the chairman of the Lighting Committee, tea and refreshments were served in the north drawing-room. The members afterwards made an inspection of the works in North-road. These are being erected for the Corporation by Messrs. W. A. Field and Co., contractors, of Brighton, from the designs of the borough engineer and surveyor, Mr. F. J. C. May, and the comparison of the size between the old buildings, which were erected only a very few years ago, and the present extensive structures very forcibly illustrates the success which the Corporation have achieved by adopting a "progressive" policy. The chimney shaft, which is of handsome design, and which is about 220ft. high, with an internal diameter of over 13ft., is quite completed, and the boiler-houses, engine-rooms, offices, etc., are receiving the finishing touches. Mr. Arthur Wright and Councillor Stafford, with other members of the Lighting Committee, were present, and gave every information to the visitors.

On Saturday morning, at the invitation of the engineer to the Hove Electric Lighting Company, many of the members visited the new station which has recently been erected in Goldsmid-road.

ERRATUM.—In our last issue we announced Mr. Panton as "representing the Electric Light Committee of Bolton." This is erroneous, and Mr. Panton writes to say that he is not a member of that committee, and was not their representative in any way.

HANLEY.

At a meeting of Municipal Engineers at Hanley last week Mr. J. Lobley, M.I.C.E., the borough engineer, in the course

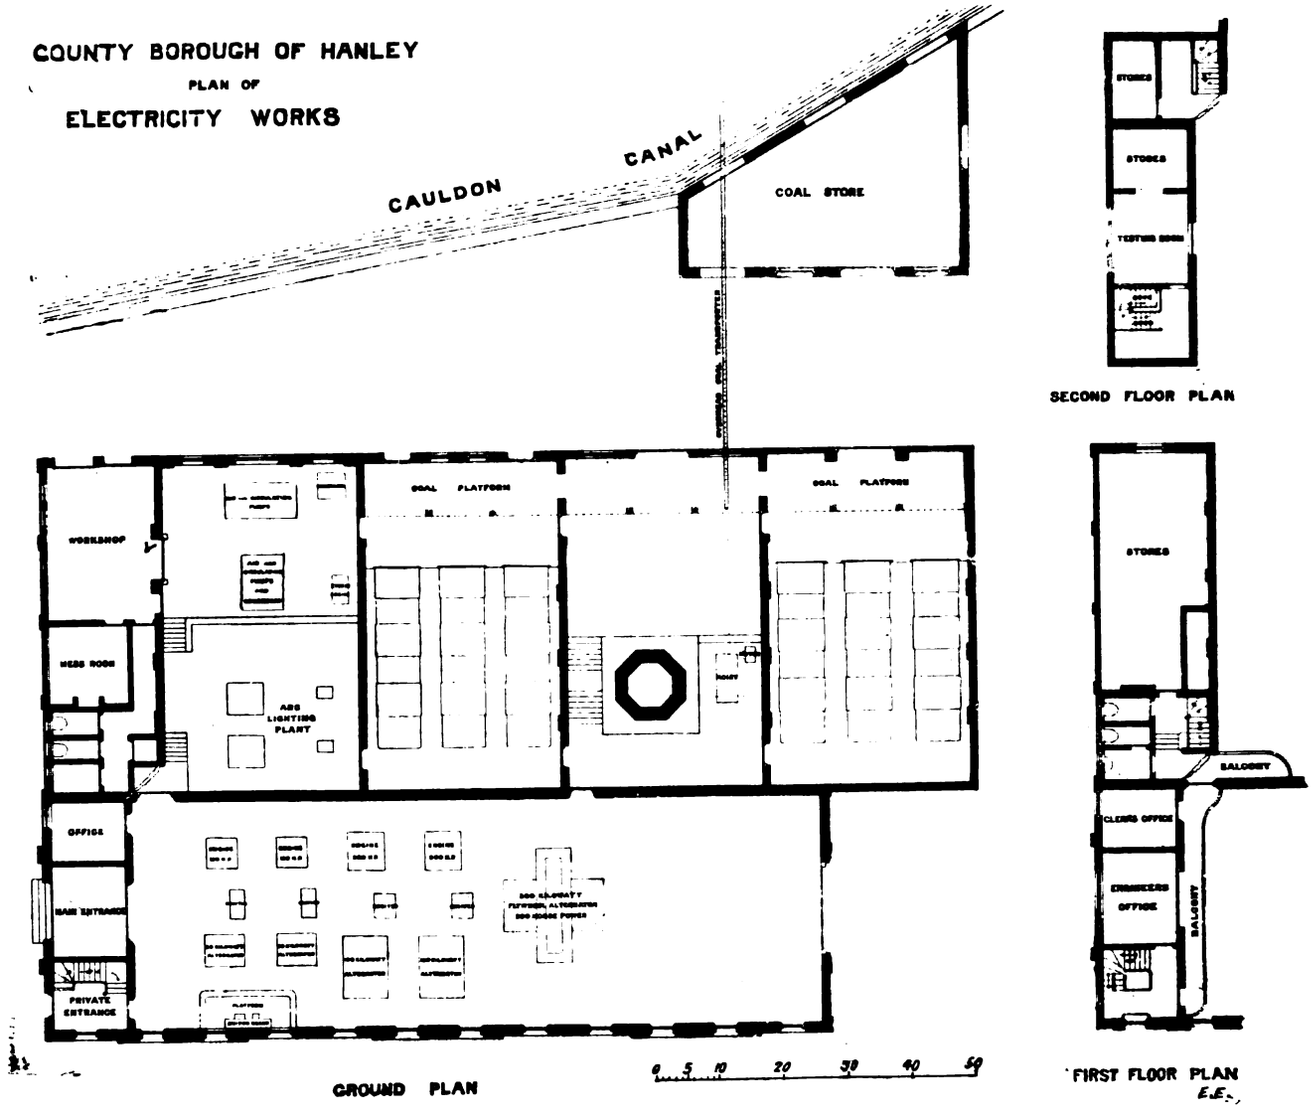
J. LOBLEY, M.I.C.E., BOROUGH ENGINEER, HANLEY.

of a paper upon recent municipal work at Hanley, made the following remarks concerning the electricity works:

Hanley Electricity Works.—A provisional order was obtained in 1891 enabling the Corporation to lay down mains and erect buildings and plant for the supply of electrical energy within the borough. The author visited America in the autumn of that year, and made special visits to the electric lighting stations in towns of about the same size as Hanley, in order to make himself acquainted with the general business engineering arrangements required. It will be remembered that at that time there were very few examples of that description in this country. The designing and carrying out of the buildings, lines of mains, erection of generating plant, and all works in connection therewith, has from the first been entrusted to the author. In September, 1892, the Council entered into a contract with the Brush Electrical Engineering Company for the boilers, engines, dynamos, mains, and sub-station transformers requisite to deal with the compulsory area lighting, both public and private, in its first stages; the system adopted being that known as high-pressure alternating current, with transformers at sub-stations, from which low-pressure distributing mains are laid to consumers' premises. The reason that influenced the Council in selecting this system as against a continuous-current scheme, as being more suitable for a district like Hanley, were principally: (1) the works could be placed away from the centre of the town, and where land is less valuable, and where, consequently, extensions could be more readily made as required; (2) the north-eastern corner of the park estate, adjoining the canal, was available as the site for the electricity works, and will be found to be very conveniently situated and but little removed from the actual centre of the area of supply. Further advantages accrue from its proximity to the canal for the supply of coal and water for condensing engines. The high-pressure mains are concentrically arranged in one cable with insulating material between the two sets of copper strands, the whole being insulated and protected by outer coverings. This cable is drawn into cast-iron pipes, forming a ring main from the works *vid* Bethesda-street and Piccadilly and the Market-square, and returning *vid* Tontine-street and Lichfield-street. The low-pressure distribution mains are not concentric, but are laid double in cast-iron troughs, afterwards filled up solid with pure bitumen. The capacity of these mains is practically increased to any extent desired by reducing the

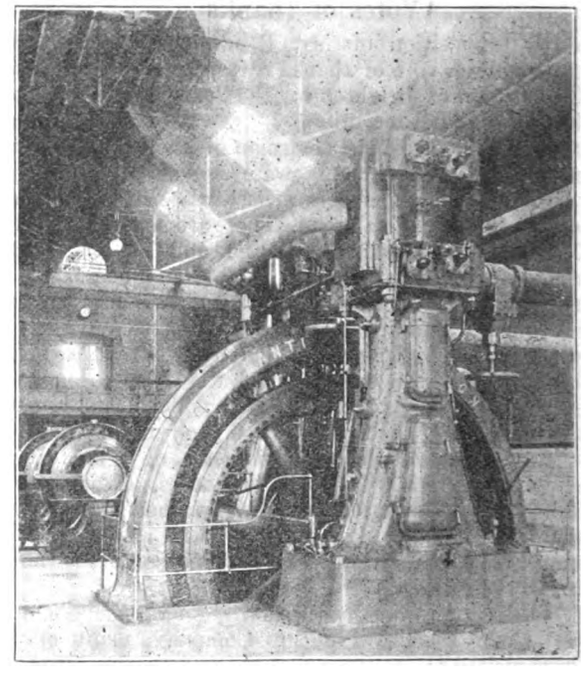
Digitized by Google

area served by them. This is done by adding transformer stations at the points of most demand.



Public Street-Lighting (within or adjacent to the compulsory area).—The contract includes provision for 30 arc lamps of 1,200 n.c.p. each—*i.e.*, 400 watts. These are arranged in series, supplied with electricity by a special cable from a continuous-current dynamo. A second engine and dynamo is provided as reserve.

Incandescent Lamps for Side Street-Lighting.—Within and adjacent to the district through which the electric light mains pass are other existing gas lamps, in addition to the 53 lamps of various sizes that were dispensed with by the establishment of the 30 arc lamps. At present it is generally conceded that arc lamps should be used for leading thoroughfares, but there are many positions, particularly in side streets, where the establishment of such a lamp is out of the question, and where an ordinary gas-burner or a 60-watt (16-c.p.) incandescent lamp would suffice. There has been laid in the same cast-iron trough with the general supply mains two separate insulated cables of small size, the whole being afterwards filled up, as before described, with bitumen. The author has devised an arrangement for lighting incandescent gas lamps in parallel without sending round the lamplighter. Where arc lamps exist in series controlled from the central station and have independent continuous-current plant and cables, the arrangement is as follows: The arc lamp cable is passed through the apparatus (which is placed at sub-stations), and whenever the arc lamp current is turned on the apparatus switches on the current from the general supply low-pressure mains to the incandescent lamps arranged in parallel. These should not exceed 20 16-c.p. lamps off one connection, so that the distance of the furthest lamp should not exceed 200 yards. When the arc lamps are turned out he apparatus switches off the current supplying the incandescent lamps, which are thus automatically lighted and extinguished by closing or opening the arc light circuit at the electricity works. The apparatus consists of a solenoid or electromagnet operating a lever; the

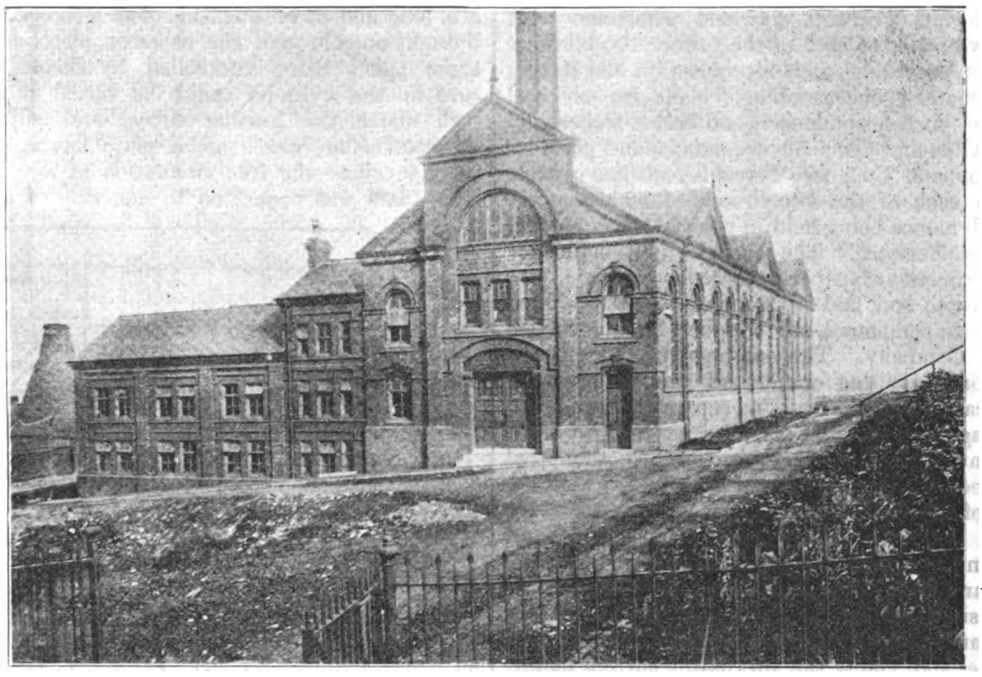


500-h.p. Ferranti Plant at Hanley, showing Brush Alternators in Background.

current of the arc lamps energises the solenoid or electromagnet, lifts the lever, and by a mercurial or other switch

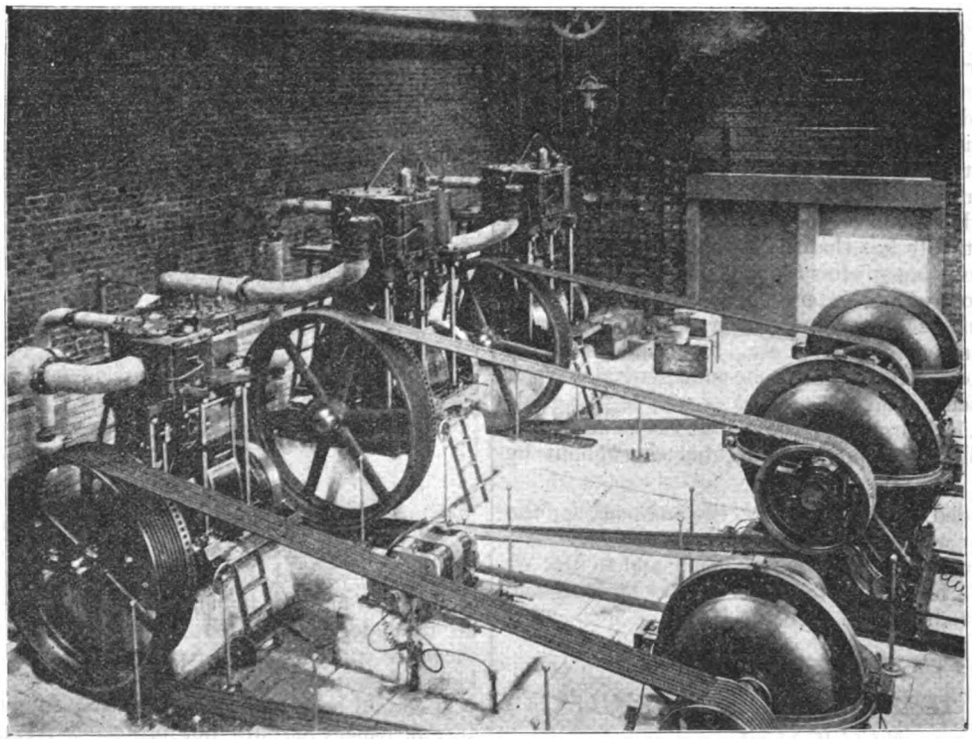
Digitized by Google

closes a low-pressure circuit for the incandescent lamps. The author believes that incandescent lamps in parallel for street-lighting has not received the attention the method deserves. He has seen many complicated arrangements of lamps in series. There are now in operation several lamps arranged as above and working satisfactorily.



Hanley Electricity Works.

No switches of any kind or "cut-in" arrangements are requisite at the lamp-post. Within half a mile of the works it is proposed to try a modification of this system devised by Mr. Sutherland. In the new roads round the park the special cables will be supplied with current at 300 volts, switched on when required at the works; in each lamp-post three lamps, 8 c.p. and 100 volts each, will be placed in series, the group of three being in parallel off the special mains. The cable used is twin lead-covered equal to 7-20 S.W.G., and even if series lighting was used it would not be advisable to use a smaller conductor than that. The first loans sanctioned were as follows: electricity works, buildings, generating plant, mains, etc., for dealing with the compulsory area of 35 acres in the centre of the town, £21,000; meters, etc., £1,000; wiring Corporation buildings, £3,000. Current was first supplied in April, 1894, and the works formally opened in the following July. The plant and mains were capable of supplying 10,000 8-c.p. lamps, and before the end of that year the demand had exceeded the safe limit, and rendered it imperative to extend the works and mains. Additional sanctions were obtained amounting to £24,000, the capacity of the works both for public and private lighting being doubled, and the mains commanding an area of 400 acres. Supply can be given to all applicants along the entire length (1¾ miles) of the main road through the borough, from Stoke Station on the south to the Burslem borough boundary on the north. The generating plant first erected was as follows: three Lancashire boilers, each 28ft. by 7ft., working pressure 120lb. per square inch; four vertical compound condensing engines—namely, two 200 i.h.p. and two 100 i.h.p.; four alternating-current dynamos—namely,



View of Dynamo-Room at the Hanley Electricity Works.

Digitized by Google

two 100, and two 50 kilowatts—each driven from engines by ropes; separate compound engine for air and circulating pump and surface condenser; two dynamos for street arc lighting, driven from two vertical compound steam-engines of 30 i.h.p. each; two 10-kilowatt continuous-current exciters driven by belts each from one of the 50-kilowatt alternators. The plant erected for the extensions consists of one 300-kilowatt Ferranti flywheel alternator with exciter, one new exciter to each of the former 100-kilowatt alternators, thus providing each alternator in the station with its own exciter; one combined plant for air and circulating pump, surface condenser, and boiler feeders, by Messrs. W. H. Allen and Co.; 30 arc lamps and posts by Messrs. Crompton and Co.; two Ferranti rectifiers capable of dealing with each of the two circuits of 30 arc lamps, the former arc dynamos being held in reserve; new switchboard by Messrs. Ferranti. The electric light mains for the extensions consist of paper-insulated concentric conductors, lead-covered and laid in troughs, afterwards filled up solid with resin compound, all supplied by the British Insulated Wire Company. The engine-house is furnished with a seven-ton travelling crane, and the boilers with Cass's mechanical stokers, driven by separate engine, and two water-storage cisterns. A platform extends in front of the boilers at a level above their tops, so that coal can be discharged into the hoppers of the stokers with the least amount of manual labour. An arrangement for lifting the coal out of a canal boat or coal-shed and depositing it on the platform has been devised by the author and carried out by the Temperley Transporter Company, who supplied their speciality; Messrs. J. Warner and Sons, of Hanley, supplying the platform traveller, and Messrs. Bergthiel and Young the alternating-current motor. The author believes that it will meet the requirements of the electricity works better than the usual form of elevators, which are no doubt well fitted for places requiring a steady constant duty. Further, the transporter can be used for lifting the coal out of a boat and depositing it in the coal store sheds, or for unloading paving or other material from canal boat to cart. In carrying out the works the author has been ably assisted by Mr. G. H. Cottam, the Corporation electrical engineer, who had the running of the works in his charge until he received the appointment of chief electrical engineer to the Hampstead Vestry, and also by Mr. C. A. Cowell and Mr. C. J. Sutherland, who were appointed last September electrical engineers and joint managers under the general direction of the author. Regarding the financial aspect of the undertaking, the ratepayers have every reason to be satisfied with the prospects. Not only did the works conclude the first completed year on December 31, 1895, with a balance in hand after paying all expenses, including interest and redemption of loans, but on December 31, 1894, with practically less than six months' running, there was a favourable balance, after discharging all obligations, including a whole year's interest on loans. The price charged per unit is 5d.; current for motive power is offered at 3d., and to churches, etc., for Sundays, at 4d. The town hall, baths, free library, museum, general market, fish market, butcher's market, school of art, higher-grade school, St. Mark's Church, and the public clocks at the old town hall and Shelton Church are lighted throughout by electricity.

[We are indebted to Mr. J. Lobley, the engineer, for the plan of extension works, and to his son, Mr. F. J. Lobley, for the photograph of the dynamo-room; and to Mr. W. Hampton, F.C.S., for the photographs of the building and the new Ferranti alternator.—Ed. *E. E.*]

EFFECT OF TEMPERATURE ON INSULATING MATERIALS.*

BY GEO. F. SEVER, A. MONELL, AND C. L. PERRY.

Of the many kinds of insulation, a few of the most common were chosen—*i.e.*, paper, cloth, oiled paper, and oiled cloth—and the following conclusions have been drawn from the result of 102 tests on samples of materials which were kindly furnished by several of the most prominent manufacturers of electrical machinery.

The Apparatus.—The heating apparatus consisted of a glass cylinder 8in. in diameter and 10in. high, covered at the top and bottom with asbestos plates. The lower part of this cylinder was occupied by 12 enamel resistance tubes 5in. long and 24 ohms each. The terminals of these were brought out through the asbestos plate. The current in these tubes being controlled by rheostat, the temperature in the cylinder could be varied at pleasure. An inch above the heating tubes, and supported by an asbestos collar, was a metal plate having holes punched in it to allow the free circulation of air in the cylinder. This plate was connected to one side of a galvanometer.

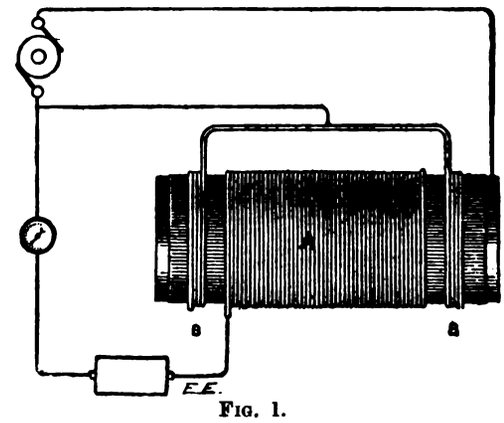


FIG. 1.

The insulating material to be tested was wrapped on brass cylinders ¾in. in diameter and 3in. long, the insulation not reaching quite to the end of the tube. The insulation was then wound with No. 26 B. & S. bare copper wire for a space of 2½in. A Thomson high-resistance galvanometer, a megohm box, and a difference of potential of 500 volts were used in the tests. The thermometer used was of the nitrogen-filled mercurial type, and capable of measuring from 0deg. to 400deg. C. When troubled with surface leakage it was eliminated in the following simple manner. The diagram shows the connections while testing a tube and also the leakage shunt. It will be seen from the diagram (Fig. 1) that all of the current going through the galvanometer must pass from the dynamo to the brass cylinder, and thence through the insulation to coil and on through the galvanometer. Any current tending to leak over the surface of the insulation from the brass cylinder to coil will be intercepted and shunted past the galvanometer by coils B B.

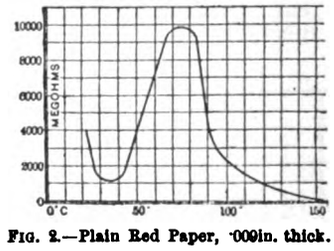

FIG. 2.—Plain Red Paper, ·009in. thick.

Plain Paper.—In this class 40 specimens were tested. After the resistance at the temperature of the air (22deg. C.) was carefully noted, the temperature was gradually increased (100deg. in one-half hour), and readings taken every 10deg. up to 80deg., and from there on every 20deg. Fig. 2 shows a curve which is characteristic of practically all kinds of plain paper.

It should be noticed, however, that in general the resistance of papers that are not protected from moisture falls between 22deg. and 50deg., and then rises rapidly until at 75deg. it has attained a maximum resistance. It should also be noted that this temperature of 75deg. is very constant for all kinds of paper. From 75deg. upwards the resistance falls rapidly, and at 150deg. is but a small fraction of its initial resistance. The initial resistance of paper protected from moisture by japan (Fig. 3) is very high, but falls rapidly with the increase of temperature, as

* Paper read before the American Institute of Electrical Engineers, May 20, 1896. Abstracted by the *Electrical Engineer* (New York.)

Digitized by Google

is the case with all material protected from moisture. (See oiled paper and oiled cloth.) Hence we see that all paper having a porous structure, and therefore containing more moisture, has a lower initial resistance than the protected paper, but is affected by heat much less than the latter. This would lead to the conclusion that there are two phenomena taking place. First, the driving off of the moisture, which tends to increase the resistance, and, secondly, some change (not a mechanical deterioration) in the material dependent on the temperature, and which may be called the temperature coefficient. This temperature coefficient tends to lower the resistance with increase of temperature. Examing the several curves shown, we see that the initial resistance of unprotected papers is low on account of the presence of moisture. Now, on gradually

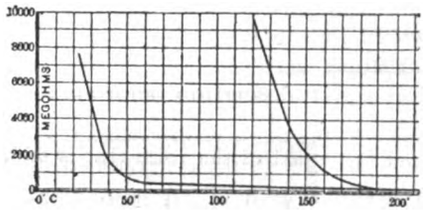

FIG. 3.—Japanned Red Paper, ·01in. Thick.

increasing the temperature the resistance falls during the first 20deg. or 30deg., because the effect of the temperature coefficient predominates during this period and before the material is warm enough to start the evaporation of the moisture it contains. This, however, lasts but a short time, as the result of the evaporation is to increase the resistance very rapidly, until at 75deg. the temperature coefficient again asserts itself and the resistance rapidly falls. In the case of japanned papers (Fig. 3) the initial resistance is very high, due to the absence of moisture, but on being heated the resistance drops rapidly as the small quantity of water contained is evaporated off so slowly that it has very little counteracting effect on the temperature coefficient. Paper does not seem to deteriorate mechanically at less than 180deg.; above this point the material begins to carbonise. At 230deg. a peculiar phenomenon takes place. The material after possessing a very low resistance from 175deg. upward, would at about 230deg. suddenly increase greatly in resistance and immediately after break down. This may be caused by some molecular rearrangement taking place at that temperature which changes the resistance of the material. Other cases wherein the resistance of a body changes at a certain temperature are well known, such as the recalescence of iron. It would seem that paper insulation has a critical temperature somewhat analogous to that of iron, steel, and nickel, but, of course, the characteristics of the materials are too different for any close similarity.

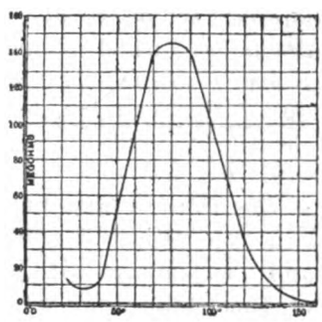

FIG. 4.—Plain Cotton Duck, ·015in. Thick.

Plain Cloth.—Under this head 20 specimens were tested, including canvas, linen, and muslin of different thicknesses. The action of this material (Fig. 4) is much the same as that of paper (Fig. 2). The initial resistance is lower, as it contains more moisture than is the case with paper; for the same reason, when the moisture evaporates off, the increase over the initial resistance is greater than with paper. By reference to the curves of paper and cloth, it will be noticed that their resistance varies in the same manner. For cloth, as for paper, the maximum resistance is at 75deg. C. The material does not begin to carbonise until at a temperature of 180deg. C., and even beyond that point it loses its mechanical strength very slowly until past 220deg.C. The explanation for the resistance of cloth varying as it does is exactly similar to that for paper.

Oiled Paper.—In this class 14 tests were made, on papers of different thicknesses. With the single exception of one specimen (the resistance of which was very high) the initial resistance was lower than in the case of paper. (Compare Figs. 2 and 5.) On increasing the temperature the resistance fell rapidly, the curve being much the same as that for japanned paper. The reason for the sudden decrease in resistance is the same as that for japanned paper. Oiled paper deteriorates mechanically at a lower temperature than paper or cloth, commencing to blacken at so low a temperature as 120deg. C.

Oiled Cloth.—In this class 28 specimens of oiled silk, muslin, and linen of various thicknesses were tested. The initial resistance of this material is much lower than that of paper, and on increasing the temperature the resistance falls rapidly, the shape of the curve (Fig. 6) corresponding to those of japanned and oiled paper. The reason for the sudden decrease in resistance is undoubtedly the same as for the japanned and oiled paper. The insulation begins to char at about 120deg. C.

General Conclusions.—In the foregoing discussion there are some main points to which it is necessary to draw attention. These are—(*a*) that paper is a better insulation and withstands increase in temperature much better than cloth (shellac and varnish were not used in any of the experiments), oiled paper, or rolled cloth. (*b*) That paper and cloth have a maximum resistance when first heated at about 75deg. C., and are not injured mechanically under

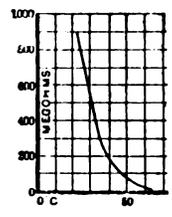

FIG. 5.—Oiled Paper, ·0045in. Thick.

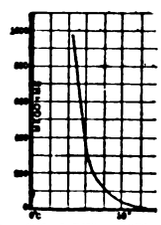

FIG. 6.—Oiled Silk, ·007in. Thick

180deg. C. (*c*) That the point of maximum resistance for paper and cloth (in this case 75deg. C.) depends on the rapidity with which the temperature is increased. The authors suggest that if the material were kept at a constant temperature until all the moisture had been evaporated the resistance of the material would then be its true resistance at that temperature. (*d*) That all give a high resistance after cooling, but have little mechanical strength. Oiled paper and oiled cloth, however, after having been heated to 220deg. C., and allowed to cool, not only have a high resistance, but become so firmly fixed to the brass cylinders that it was found necessary to remove them with a file. (*e*) That it would be well to bake paper and cloth insulation to 140deg. C. before applying varnish or shellac. (*f*) Referring to Fig. 3, it will be seen that on decreasing the temperature the resistance increased, but the second curve does not by any means coincide with the first. On further experimenting in this direction, it was found that there is no temperature at which the curve with falling temperature coincides with the first. This may be due to more moisture being driven out at higher temperatures which is not absorbed by cooling.

Here it may be well to mention an interesting phenomenon that occurred in connection with this investigation. When the temperature has risen above 100deg. C., the zinc in the brass cylinder begins to leave its surface and combine with the copper wire wrapped about the insulation, so that the wire has a brass surface and the brass cylinder a copper surface.

Sale of Electrical Machinery.—In this issue Messrs. Bradshaw Brown, Hooper, and Price advertise that they will sell by auction on June 30, at 11 for 12 o'clock, various engines, electrical plant, etc. The sale will take place on the premises of the London and Lancashire Electric and General Engineering Company, Kingsland-green, Dalston Junction, N.E.

KELVIN.

Glasgow in the first instance specially—accompanied by the whole world of contemporary science and learning as well as those who sit in high places—has during the past week been proud to do honour to Lord Kelvin. For fifty years has Lord Kelvin filled the professorial chair at Glasgow University; for fifty years and more has he stood in the forefront of science. Glasgow in the first place celebrates the jubilee of her renowned professor. We all ask to combine in the celebration of this jubilee as being in honour of one of the world's intellectual giants. We are hero worshippers at the shrine of genius, and well pleased at the opportunity given to the world to express its admiration and appreciation before it has lost

> the touch of the vanished hand
> And the sound of the voice that is still.

It is only those who stand somewhat within the realms of science that can fully understand the true meaning of the length and breadth and mighty depth of Kelvin's labours. The workaday world sees a formula which guides the calculations of its engineers, but it has no conception of the labour involved in obtaining that formula, nor the money and time saving medium that formula really is. A sentence or a formula may embody the work of a lifetime, and confer benefits upon humanity out of all proportion to the honours which may be showered upon the discoverer. Thus it is in the case of Lord Kelvin. We know where we stood before he commenced his labours, and we know how simple some things are now which were then deemed impossible. We know the routine of the civilised world has been changed largely by his genius, and no honours conferred upon the man, or words of approbation, can adequately convey the world's appreciation of these facts. Glasgow has been unanimous in paying honour to her gifted citizen, and congratulatory telegrams and addresses have been sent from all quarters of the world, from the Queen and Prince of Wales downwards. Elsewhere we give two memoirs of our hero—one from the *Scotsman*, the other from the *Times*. Our readers are perhaps better able than the major portion of the non-scientific community to understand Lord Kelvin's unique position, not only among scientific men of this country, but in the whole world. In electrical matters he can hardly be said to have a rival, for not only as a theorist does he stand in the front rank, but by combining practical with theoretical work he has given to the world so many pieces of apparatus unrivalled of their kind that we can only stand and wonder. Fifty years ago—1846—what was the position of applied electricity then? Three years before—in 1843—a return was made to the House of Commons in connection with the Admiralty semaphore from London to Portsmouth. That was the system electric telegraphy was destined to replace. That semaphore cost from three thousand to three thousand five hundred pounds a year, and was worked five hours a day in winter and seven hours a day in summer, while on an average it could not be worked during one hundred and eight days in the year

Digitized by Google

at all—at all. Shade of Monte Christo, where art thou? The sprig of 1843 is universal to-day. A year after Lord Kelvin—then Prof. W. Thomson—entered upon his duties, the length of telegraph lines in Great Britain only reached a thousand miles, a length reached in America the year of his election. Prof. Thomson must have been well acquainted with the birth of the telegraph, for he even then had devoted his attention to the study of electricity. But his special work in this direction came later on when men of enterprise entered into the question of connecting the Old and the New World by a submarine cable. Their trials, their failures, and their successes, are they not told in the annals of that time? And what a glorious part Prof. Thomson played in obtaining success. For this he received the honour of knighthood. We have no wish to trace the progress of applied electricity as Lord Kelvin has seen it, and in which he has ever held a foremost place. Then telegraphy was just making headway, cable work hardly dreamt of, electrolytic work on a large scale unknown; the dynamo—the creation of Faraday—existed more in the cruder forms of motors driven by batteries; electric light, electric transmission of power only daydreams; telephony lay in the dim and distant future. Now, on the day of his professorial jubilee, these are accomplished facts, so common that they have ceased to excite curiosity. The part played by Lord Kelvin in every new departure has been important. He made long-distance cables possible, he has given us instruments and apparatus of precision so admirable, in fact, that electrical measurements are probably far more exact than any other measurements of whatever kind. But there is another phase of his life's work that is more often than not completely forgotten. Directly and indirectly he has influenced the lives of hundreds of students. This influence is felt pulsating through all scientific circles from Japan on the one side, by Asia, Africa, and Europe to America on the other side. The inventor and the discoverer may only be put side by side with the teacher, the one genius embodying in the highest degree these three phases of interest to civilised humanity, any one of which would satisfy the ambition of an ordinary mortal and render him a hero to his fellows.

THE INSTITUTION AND LORD KELVIN.

As might have been expected, the Institution of Electrical Engineers has been among the most earnest and most sincere well-wishers of Lord Kelvin upon the occasion of his jubilee at Glasgow.

The President, Dr. J. Hopkinson, F.R.S., in presenting the address, said:

The Institution of Electrical Engineers acknowledge that you are in a very literal sense the father of their profession. You have done more, much more, than any other man in this or any land to place that profession in the honourable position it now occupies. The Institution have deputed me, their president, to hand you this address as a token of hearty love and esteem from your children.

The following is the address:

To the Right Honourable Lord Kelvin, D.C.L., LL.D., Past-President of the Royal Society.

We, the President, Council, and Members of the Institution of Electrical Engineers, desire hereby to offer to your lordship our sincere and hearty congratulations on the occasion of the jubilee of your professorship of Natural Science in the University of Glasgow.

It will ever be a source of pride and satisfaction to this Institution that one who occupies so pre-eminent a position in the scientific world should have been its first president in 1889, besides having been an original member and president in 1874 of the same association, when it existed under the name of the Society of Telegraph Engineers.

Not only have you contributed more than any other living man to our knowledge of the laws of nature, but you have found time to perfect practical applications of science wherefrom every branch of the electrical engineering profession has derived special benefit.

We desire, in conclusion, to express our fervent wish that you may continue for many years to enjoy the blessings of good health, and that science may still further benefit by your labours.

John Hopkinson, *President.*
F. H. Webb, *Secretary.*

LORD KELVIN'S JUBILEE.

The *Scotsman* of June 15 gives the following interesting details of Lord Kelvin's career:

In view of the jubilee a brief reference to some of the leading features of Lord Kelvin's life and work may not be without a special interest. Lord Kelvin is a scion of the Scoto-Irish race of Ulster—a race, by the way, wonderfully prolific in genius. He was born in College-square, Belfast, on June 25, 1824. His father, Dr. James Thomson, was at the time Professor of Mathematics in the Royal Academical Institute, Belfast, but in 1832 he received an appointment to the Chair of Mathematics in the Old College of Glasgow. At the early age of 11 the future Lord Kelvin became a student at Glasgow College—having up till that age been under the personal tuition of his father; and at college his marvellous rapidity in solving problems quickly made itself apparent. From Glasgow he passed to St. Peter's, Cambridge, where he graduated in 1845 as second wrangler and first Smith's prizeman, a university examiner remarking that although he had only taken second place, the first wrangler was "unworthy to cut Thomson's pencils for him." He was immediately elected a Fellow of his college. While at Cambridge he began at the age of 17 to contribute to the *Cambridge and Dublin Mathematical Journal*, and his writings speedily attracted the attention of savants. His earliest contributions to physical science were a defence of Fourier in answer to a charge of erroneousness which had been brought against some of the fundamental formulas of his harmonic analysis, and a paper on "The Uniform Motion of Heat in Homogeneous Solid Bodies, and its Connection with the Mathematical Theory of Electricity," the spirit of the latter running through much of Lord Kelvin's subsequent work. In this paper he pointed out the analogy between the theory of the conduction of heat in solid bodies and the theory of electric and magnetic attraction, and aiding himself with this analogy, made use of known theorems as to the conduction of heat in order to establish some of the most important theorems in the mathematical theory of electricity; and in conjunction with Faraday's researches on electrostatic induction it proved of the highest value in the discussion of questions in electrostatics and also in magnetism. A paper on "The Linear Motion of Heat" was another contribution to scientific literature made by him about the same time, and in which there was contained the foundation of the method of evaluating absolute geologic dates from underground temperature. This paper was delivered on the occasion of his being installed as professor at Glasgow University, and when he was in his twenty-second year. In this same year he became editor of the *Cambridge and Dublin Mathematical Journal*, also contributing papers to *Liouville's Journal de Mathematique*, one of his earliest papers on "Laws of Statical Electricity" having appeared in this publication while he was studying at Paris in the laboratory of the famous Regnault. Papers on electrostatics and magnetism appeared at frequent intervals from his pen. One of the most notable first appeared in the French journal already named. In it Thomson unfolded the

Digitized by Google

principle of "electric images," by means of which he showed by simple geometrical principles the way to solve many problems of an apparently very complicated nature as to the distribution of electricity on a system of conductors under the influence of a given electrified system. His electrostatic researches led him to the invention of an instrument for electrostatic measurement, and his labours in this direction produced the quadrant electrometer which is employed for all kinds of electric testing in telegraph construction and for the registration of atmospheric electricity at Kew Observatory; a portable electrometer for atmospheric electricity and other purposes in which extreme sensitiveness of the quadrant electrometer is not required; and the absolute electrometer, which serves to reduce the scale readings of other instruments to absolute measure, and was used by Lord Kelvin in his measurement of the electrostatic forces producible by a Daniell's battery. In other directions he was at the same time making important investigations, as was shown by the series of papers on the "Dynamical Theory of Heat" which he communicated to the Royal Society of Edinburgh, and in which he placed the whole science of thermodynamics on a thoroughly scientific basis. Among the most important results of his investigations in this connection was his discovery of the principle of the dissipation of energy, which he announced in 1852. Three years later he made another important announcement in his discovery of the electric convection of heat, and also of a number of new relations between thermal and electric properties of matter. At different times there followed papers in which he calculated the size of atoms, and went the length of laying down an hypothesis regarding their formation. He has also published a memoir on the mechanical energies of the solar system, and on his determination regarding the rigidity of the earth, in addition to researches on the tides and on vortex motion. His address as president of the British Association at Edinburgh in 1871 was particularly notable from the fact that it was in his most popular style. In it he discussed the question, "How did life originate on the earth?" and his concluding sentence ran: "The hypothesis that life originated on this earth through moss-grown fragments from the ruins of another world may seem wild and visionary; all I maintain is that it is not unscientific." His later contributions have, for the most part, been a development of investigations previously entered upon.

While Lord Kelvin's scientific renown is regarded by savants as culminating over his experimental and mathematical researches in the various departments of natural philosophy, the public knows him chiefly through the inventions which he has made concurrently with his work in the application of mathematics to the solution of physical problems. To the public at large he first became known in connection with the laying of the Atlantic cable. Along with the late Mr. Cyrus Field he was the chief means of bridging the gulf of communication between Europe and America, and of accomplishing a feat greater than that of Puck, when this sprite boasted that he would put a girdle round the earth in 40 minutes. When the first cable was proposed the difficulty of the retardation of signals was still unsolved. The question therefore arose as to whether it would be possible to make communication between Europe and America pay, as the transmission of a signal took six seconds to pass across the Atlantic. His investigations led to a true understanding of the nature of the phenomenon of retardation and to the invention by himself of an instrument—the "mirror galvanometer"—which obviated the lagging of the electric currents, and enabled the communication to be registered without delay. In brief, he made submarine telegraphy as successful as land telegraphy. The original cable was laid in 1858, but within a fortnight it failed, and it was not until 1866 that the Old World and the New were finally and successfully coupled together. When he returned home, Mr. Thomson, as he then was, received the honour of knighthood. With the cable in working order, Sir William continued to devote his attention to this practical branch of electricity, and as the "mirror" instrument left no trace of the message transmitted, which had to be written down by the receiving clerk, this led to his invention of the "syphon recorder," by means of which a permanent record of all messages is secured, and it is now employed at almost all submarine stations. During many of his investigations in connection with submarine telegraphy, Sir William had the assistance of the late Mr. C. F. Varley, F.R.S., and the late Prof. Fleeming Jenkin. Sir John Pender was the first to adopt the "syphon recorder" in the year 1870. In conjunction with Prof. Jenkin, Sir William acted, between 1869 and 1875, as engineer for the French Atlantic cable, the Mackay-Bennet Atlantic cable, the Brazilian and River Plate and the West Indian cables.

In 1873, while on his way to South America in connection with the laying of the Brazilian and River Plate cables, Sir William made his first experiment with his now well-known apparatus for sounding the deep sea with a steel pianoforte wire instead of by the ordinary lead-line. This invention consists of a pressure gauge, which, thrown overboard at the end of a wire, accurately records the depth of water while the vessel is going at full speed. With the old lead-line soundings could only be taken once an hour, whereas with the new instrument it is possible to take a cast once every 10 minutes. But while he has invented many apparatus for assisting seamen in the navigation of their vessels, the most important is his mariner's compass. This invention came about in rather a curious manner. He had undertaken in 1874 to contribute a short series of articles to a popular magazine on the mariner's compass, but while gathering material for the papers he became alive to the faults of existing compasses, and between the publication of the first of the articles and the second there was a lapse of five years, Sir William in the meantime having invented a mariner's compass of exquisite construction, which enabled the errors arising from the magnetism of iron ships to be accurately corrected. The story is told that Sir William sent his compass to Sir George Airy at the Royal Observatory for his inspection, and that Sir George after examining it shook his head and ejaculated, "It won't do." When Sir William heard of this, he merely remarked "So much for the Astronomer Royal's opinion!" The Admiralty also rejected it, but to-day the maritime world is in agreement with the captain of the Cunard liner who not long ago said, "Lord Kelvin's sounding machine and compass have done more for the safety of navigation than any invention since the first compass and sextant. The cherub up aloft who watches over poor Jack always takes in my eye the shape of that clever and wise Scotsman who has given us the best chance of getting safe to port." Lord Kelvin's "Tables for Facilitating the Use of Sumner's Method of Ascertaining a Ship's Place at Sea" are regarded as of very high importance, and his machine for predicting the level of the tides in any part of the world is one of the most notable of his non-electrical inventions, which range down to the humble domestic water-tap. Of late years Lord Kelvin has also identified himself largely with the work of introducing the electric light both for public and domestic purposes.

In addition to valuable work on different Royal Commissions, Lord Kelvin is a voluminous author. Apart from his contributions to pure science and his writings on "Navigation," he is the author, in conjunction with Prof. Tait, of Edinburgh, on a treatise on natural philosophy, which is used as a class-book. His "Popular Lectures and Addresses," however, while affording a great intellectual treat, even require a vigorous mental digestion. He is, like his late brother, the coiner of a considerable number of scientific expressions. Among these are "mho," "motivity," "diffusivity," "infinitesimal satellites," and "irrotational circulation." The words of a recent writer in summing up Lord Kelvin's position in the scientific world may here be given: "In heat his name is coupled with those of Joule and Rankine; in the dynamical theory of gases with Clausius and Helmholtz; and in electricity and magnetism with Faraday and Maxwell. . . . Apparently his name will go down to posterity with those of Galileo, Newton, and Pascal. So far he is unique in science by reason of his multifarious and diversified career. His achievements would suffice to make at least three eminent reputations, for not only is he

Digitized by Google

the greatest physicist of the day, but the leading electrical engineer and one of the most celebrated inventors. He is the Napoleon of science." That his merits have not gone unrecognised by the world may be seen from the honours heaped upon him. He is an LL.D. of Cambridge, Edinburgh, Dublin, and Montreal; a D.C.L. of Oxford; a past-president of the Royal Society of Edinburgh, a past-president of the British Association, a past-president of the Royal Society (having been the first Scottish professor to hold that office), a past-president of the Institute of Electrical Engineers, a foreign associate of the French Academy, a Grand Officer of the Legion of Honour of France, a Knight of the Order Pour le Merite of Germany, and a Commander of the Order of Leopold of Belgium. In addition to all these and other titles which he holds, he was made a peer of our own realm in 1892.

Lord Kelvin has been the recipient of many tokens of the esteem in which he is held by the citizens of Glasgow, his fellow professors, and also the students, who have been attracted to his classroom from every part of the world. He was entertained to dinner after each mark of Royal favour, and a few years ago he was publicly presented with his portrait. At the time of his election as president of the Royal Society the students at the University of Glasgow presented him with an address, in which they stated that he had "gained their warm esteem and unaffected admiration by his uniform courtesy and kindness, as well as by his rare gifts as a scientist and a scholar." It may be mentioned that in 1855, when Lord Kelvin was making his investigations into the question of the "electric convection of heat," he called in his students for the first time to aid him, and that from that time onward he has invited and received their co-operation in the university physical laboratory, now under the superintendence of himself and his gifted nephew and assistant, Dr. J. T. Bottomley, F.R.S. Lord Kelvin has all his life regarded athletic exercises and pastimes with favour, and this has added to his popularity among the students. While at Cambridge he frequently took part in university rowing competitions, and won the Silver Sculls. He was also president of the Cambridge University Musical Society. In the early days of the volunteers he was an enthusiastic soldier-citizen, and it was while curling that he received an injury—now fully 30 years ago—which left him permanently lame. For many years he also spent the summer vacation in his own yacht. In Lord Kelvin the students have found that the best teacher of a science, even of the elements of a science, is not the man of plodding and painstaking mediocrity, but the original thinker and investigator, who succeeds by his own enthusiasm for his subject in awakening in younger minds an interest and enthusiasm for it akin to his own. It need only be added that amidst all his accumulated honours Lord Kelvin is as simple, gentle, and unpretending as he is able and accomplished. The fact is so well known it is scarcely necessary to mention that he took a very active part in the agitation against Irish Home Rule, and that since 1886 he has supported the Unionist party, having previously been a follower of Mr. Gladstone. Lord Kelvin has been twice married. The present Lady Kelvin, whom he married in 1874, was a daughter of Mr. C. R. Blandy, of Madeira.

The *Times* has the following article on

The Electrical Inventions of Lord Kelvin.

It would be impossible to write the history of electrical discovery and invention in the last 50 years without reference to that immense share which Lord Kelvin has had in it. His contributions to it have not only been on the purely scientific side without equal, but, what is also remarkable, he has shown unusual power in bringing to bear abstract principles in the construction and invention of instruments having a most practical value. Broadly speaking, his practical electrical inventions fall into three great groups—first, those connected with telegraphy and submarine cables; second, those connected with navigation and the mariner's compass; and, thirdly, those connected with instruments of precision for electrical measurements. This by no means exhausts the series, but it is sufficiently distinctive.

The mathematical theory of the speed of telegraphic signalling through submarine cables was given by Lord Kelvin to the Royal Society in a paper communicated in 1855, entitled "The Theory of the Electric Telegraph." When the project of an Atlantic cable was first mooted Lord Kelvin established, in the face of some opposition, the true principles on which the speed of such signalling would depend, and in 1857 invented his celebrated mirror galvanometer, which was first used for sending signals through the short-lived 1858 Atlantic cable. In this instrument a very small magnetised fragment of a watch-spring has attached to it a tiny mirror, and the little magnet is suspended by a fibre of cocoon silk in the interior of a coil of wire. When the electric current is sent through the coil it causes a movement of the magnet, and this is indicated by the movement over a scale of the image of a spot of light reflected from the mirror. The telegraph clerks learn to interpret the erratic motions of this spot of light to and fro, and they are arranged to form a code of signals on the basis of the Morse alphabet. This simple device solved one of the problems in submarine telegraphy—viz., an instrument which would "receive" fast enough to render submarine telegraphy commercially possible. This was succeeded in the following years by the spark recorder, and finally by the syphon recorder, an instrument constructed to receive and record on a strip of paper the signals sent through long submarine cables. The first patent for this syphon recorder was obtained by Lord Kelvin in 1867, and the three succeeding years saw great improvements effected in it. This instrument is now the typical receiving instrument both for long and short submarine cables. These two instruments, first invented for cable work, have reappeared in various laboratory forms of late years. Every electrical laboratory has its mirror galvanometers and movable coil galvanometers, which, by whatever name they are called, are Lord Kelvin's invention.

An important invention in connection with submarine telegraphy was Lord Kelvin's automatic curb sender, an instrument devised to increase the rapidity of sending signals through submarine cables. By the use of a punched slip of paper like the card of a Jacquard loom, the rate at which signalling could be conducted was facilitated. It is impossible to omit in this connection mention of the valuable contributions of Lord Kelvin to the theory of cable-laying and to the various branches of the mechanics of submarine cable work. This, in conjunction with the mirror instrument, the syphon recorder, and the establishment of the true theory of electric signalling, laid the solid foundation on which commercial enterprise has established the vast industry of submarine telegraphic communication.

Then in respect of inventions connected with navigation Lord Kelvin's mind has been no less fertile. Bringing to bear the fullest scientific knowledge to the improvement of the mariner's compass, he has introduced into its construction the most valuable changes. He investigated with most complete care the causes of compass disturbance in iron ships and applied means to correct these disturbances. Although not strictly electrical inventions, it is hardly possible to refer to the compass without at the same time alluding to the improvements Lord Kelvin has effected in deep-sea sounding. By the ingenious use of pianoforte wire instead of rope, and a special depth indicator, he was able to effect soundings at great depths and even from a ship in motion. He has brought to bear the most exquisite mathematical skill in the construction of instruments for predicting the rise and fall of the tide in any place, based on a knowledge of one year's actual record as taken with an automatic instrument, and he has thus provided the navigator with improved instruments for his craft in three of the principal departments of his work. Lord Kelvin, be it remarked, is a practical navigator himself, and his yacht "Lalla Rookh" had been the scene of much experimenting before the above navigational inventions were perfected.

Turning, then, next to his inventions in electrical measuring instruments, it is not too much to say that he

Digitized by Google

has revolutionised every department of them. In 1857 Lord Kelvin first described the instrument which afterwards developed into his quadrant electrometer and finally into the portable and absolute electrometers. These first instruments were developed in the course of his early studies in atmospheric electricity, in the progress of which he perfected every instrument required for that branch of observation. Electroscopes or electrometers, prior to the invention of the forms devised by Lord Kelvin, could hardly be classed as instruments of precision, but when he had completed their reconstruction they became invaluable as instruments of exact research. In later years Lord Kelvin has devised his electric balances for weighing electric currents, electrostatic voltmeters for measuring electrical potential difference or pressure, electric watt-meters for measuring electric power, and electric erg-meters for measuring electric energy. These instruments are found in every laboratory, electrical workshop, and electric station. In each and every one of these instruments is to be discovered some mechanical or electrical principle admirably applied. No measurements in the whole region of physics can now be made with greater accuracy and over greater ranges than those in electricity, and in every department of electrical measurement Lord Kelvin has contributed some invaluable apparatus or method. We find also rheostats, condensers, bridges, and numerous details of electrical apparatus stamped with the impress of his originality. It is hardly exaggeration to say that if we could take out from our knowledge of electrical measuring instruments all that Lord Kelvin has contributed in the way of practical invention the remainder would be exceedingly small. It is difficult to draw a sharply-marked line between Lord Kelvin's contributions to electrical theory and practice. His collected mathematical and physical papers, as well as popular lectures and addresses, show how closely the two are connected in his work. His theoretical contributions to electricity began in 1842 in a paper on "The Mathematical Theory of Electricity," and have continued in an unceasing stream ever since. His great papers in 1856 on "The Electrodynamic Qualities of Metals," on "Thermoelectric Phenomena," on "Effects of Stress and Strain on the Electric Qualities of Metals," all mark epochs in the history of the science.

In the preface to his great treatise on "Electricity and Magnetism," the late Prof. Clerk Maxwell remarks that when he first began to study electrical physics he resolved to read no mathematics on the subject until he had first read through Faraday's "Experimental Researches on Electricity"; and he states his indebtedness to Lord Kelvin for having first directed his attention to the fact that Faraday's method of viewing electrical phenomena was different from that of most other mathematical physicists. When we remember the supremely important consequences which have followed from Maxwell's study of the work of Faraday, it may well be questioned whether any service which Lord Kelvin has rendered to electrical science has a higher value than that which he rendered in directing the mathematical genius of Maxwell to a contemplation of the experimental work of Faraday. But Lord Kelvin has united in himself a large share of the experimental skill of the one as well as the mathematical ability of the other. He has, indeed, a larger reach in many respects than either, for to the precision and definiteness of aim given by the power to wield mathematical weapons with enormous effect he unites an almost inexhaustible ingenuity in experimental skill, enabling him to realise abstract conclusions in practical appliances, and whether he is considering the harmonic analysis of a tidal curve, a vortex theory of matter, an electrical theorem, or a proposition on crystallography, he finds his goal in a machine or an instrument which embodies in a concrete form his theoretical deductions. It is this combination of qualities which has made him so effective as a scientific worker and given to his achievements such an eminent vitality and power to stimulate other minds. He has in all aspects of his work a definiteness of purpose which brings him at once to the boundary from which he takes a fresh departure into the unknown, and to which he has but rarely returned without the spoils of victory in the form of some new practical invention or suggestive theory.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

The subject of alternating currents, at one time considered to be one of the most abstruse in the domain of electrical engineering, has recently been brought within the mental reach of many students to whom formerly the task of grappling with it appeared quite hopeless. This is mainly due to the development of special elementary methods for dealing with alternate-current problems, for the introduction of which we are indebted to Blakesley, Kapp, Ferraris, and others. In this we have merely one illustration of the fact that the clearer the insight we gain into natural phenomena, the easier does it become to interpret them by the aid of methods which do not make too large a demand on the mental powers of those whose previous training is somewhat inadequate.

In what follows it will be supposed that the student is familiar with a little elementary algebra, and that he has mastered the fundamental principles of continuous-current phenomena. A knowledge of the C.G.S. electromagnetic system of units and their connection with the practical units will be assumed. If the student has studied trigonometry, so much the better. But for the sake of those whose mathematical studies have not extended beyond algebra the little trigonometry that will be required in what follows will be briefly explained. Should the explanations given be found too brief, the student is advised to refer to one of the many elementary text-books on the subject.

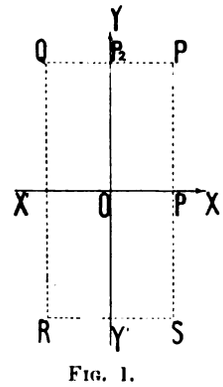

FIG. 1.

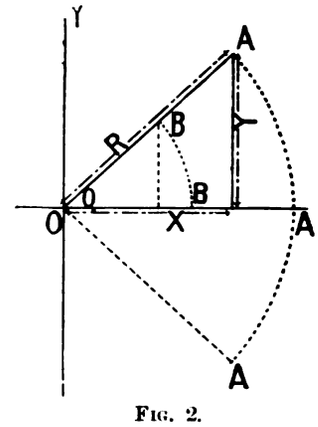

FIG. 2.

1. Take two straight lines, X′ X and Y′ Y (Fig. 1), intersecting each other at right angles in the point O. The position of any point P in the plane of the paper may be specified by assigning its perpendicular distances P P_1 and P P_2 from the two lines X′ X and Y′ Y respectively. The two reference lines X′ X and Y′ Y are termed the two *co-ordinate axes*. Their point of intersection O is called the *origin*. The distance P_2 P (= O P_1) of P from the vertical axis is called the *abscissa* of P, and its distance P_1 P (= O P_2) from the horizontal axis is called the *ordinate* of P. The abscissa and ordinate of P are sometimes spoken of as the *co-ordinates* of the point P. If x and y stand for the abscissa and ordinate of P respectively, the point P is denoted by enclosing its co-ordinates in brackets, thus: (x, y).

Let P Q R S be a rectangle, such that P_1 S = P_1 P, and P_2 Q = P_2 P. Then it is obvious that the co-ordinates of all the four points P, Q, R, and S have the same *numerical* values. In order to avoid ambiguity, we agree to regard distances measured to the right of the axis Y′ Y as positive, those measured to the left as negative; distances measured above X′ X as positive, below X′ X as negative. Hence, if x and y denote the *numerical* values of O P_1 and O P_2 respectively, the four points P, Q, R, S taken in succession are denoted thus:

$$(x, y);\ (-x, y);\ (-x, -y);\ (x, -y),$$

and there is now no ambiguity. The positive direction of

* Based on a series of evening lectures delivered at the University College, Liverpool.

Digitized by Google

the horizontal axis is thus from left to right, and the positive direction of the vertical axis from below upwards, as indicated by the arrow heads in Fig. 1.

The problem of finding the position of a point P whose co-ordinates x and y are given presents no difficulty. We have merely to lay off from O a distance $O P_1 = x$ along the horizontal axis, and a distance $O P_2 = y$ along the vertical axis. Through the two points P_1 and P_2 we draw two lines parallel to the two axes respectively, and their intersection determines the point required.

2. Let a straight line O A (Fig. 2) be made to turn round one of its extremities, O, in a *counter-clockwise* direction until it comes into the position O A′. The angle $A O A' = \theta$ which the line has swept out is reckoned *positive*. If the line had swept out an equal angle A O A″ by turning in a *clockwise* direction round O, the angle would have been reckoned *negative*. Angles are commonly measured in degrees, minutes, and seconds. But for mathematical purposes it is much more convenient to adopt another method of measurement, which is as follows: Measure the length of the arc A A′, and divide it by the length of the radius O A; the quotient gives the *circular* or *radian* measure of the angle A O A′. It is obviously immaterial what radius we choose; for by taking a shorter radius, such as O B, we merely alter the scale of our diagram, but do not change the ratio of the arc (B B′) to the radius (O B). If the ratio of the arc to the radius is unity, we have a unit angle, or *radian*. Since the length of the circumference of a circle of radius r is $2\pi r$, the radian measure of four right angles is 2π; of two right angles, π; of one right angle, $\frac{\pi}{2}$; and so on.

Let in Fig. 2 O be taken as origin, and O A as one of the co-ordinate axes. Through O draw the other co-ordinate axis O Y. Let the length of the revolving line O A′ be r, let θ stand for the angle A O A′, and let x, y denote the co-ordinates of the point A′. Then

$\frac{x}{r}$ is called the cosine of θ, and is denoted by $\cos\theta$;

$\frac{y}{r}$ is called the sine of θ, and is denoted by $\sin\theta$;

$\frac{y}{x}$ is called the tangent of θ, and is denoted by $\tan\theta$.

These ratios are called *trigonometrical* or *circular functions* of the angle θ.

An inspection of Fig. 2 will easily convince the student of the truth of the following statements:

The cosine and sine of an angle are capable of assuming any values between -1 and $+1$.

The tangent of an angle may have any positive or negative value, however great numerically. As the angle approaches a right angle $\left(\frac{\pi}{2}\text{ in radian measure}\right)$, its tangent increases indefinitely.

It is hardly necessary to draw the student's attention to the fact that a change in the length of the line O A′ ($=r$) will merely alter the scale of our diagram, and will not affect the values of the ratios $\frac{x}{r}$, $\frac{y}{r}$, and $\frac{y}{x}$.

3. When two quantities are so related that the value of one of them is dependent on that of the other, we say that the first quantity is a *function* of the second. Thus, if we consider the current in a circuit of given resistance, we know that the current will depend on the E.M.F. We may therefore say that the current is a function of the E.M.F. Again, taking the E.M.F. of a given dynamo running at a certain speed with a given external resistance, we may say that the E.M.F. of the dynamo is a function of the speed (*i.e.*, it is dependent on, or determined by, the speed). Corresponding to any value of one of the quantities considered, we have a certain value of the other quantity. This at once suggests a method of graphically representing the connection between the two quantities, for we have merely to regard the values of one of the quantities as the abscissæ of certain points whose ordinates are the corresponding values of the other quantity or function. Such a series of points will lie on a certain curve, and the curve shows us at a glance how the two quantities are related. Such a curve is termed the *graph* of the corresponding function.

4. In most of the cases which will claim our attention we shall have to deal with quantities whose values are constantly varying as time goes on, so that their values will depend on the particular instant of time at which we consider them; in other words, we shall have to deal with quantities which are *functions of the time*. The variation of such functions is conveniently represented, as explained in the preceding section, on a sheet of squared paper, by plotting the values of the time as abscissæ, and the corresponding values of the function as ordinates. Fig. 3 is an example of how this may be done, and exhibits the changes in the E.M.F. of a certain alternator during ·004 of a second.

Most of the time-functions with which we shall have to deal exhibit a certain peculiarity—viz., they run through a certain cycle of values which is repeated time after time. Such functions are termed *periodic* time-functions. The time taken by the function to go through the complete cycle of values to which it is restricted is called the *periodic time*, or simply the *period*, of the function. If, then, we choose any one value which the function is capable of assuming, this value will be repeated at equal intervals of time, each interval being equal to the period of the function.

5. Let us consider any function of the time, and study the manner in which the function changes as time goes on. In the case of some functions we may find that equal changes in the function take place in equal intervals of time. When this is the case, the function is said to change at a *constant rate*, and we define the *rate of change* of the function as the *change which it undergoes in unit time*. In

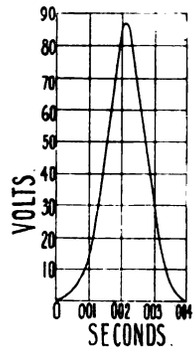

FIG. 3.

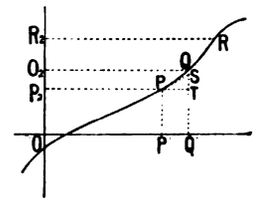

FIG. 4.

the case of most functions with which we shall have to deal, however, the changes which take place in the value of the function during equal intervals of time are unequal. In such a case we say that the rate of change of the function is variable, and we define as the *average rate of change* of the function *during any interval of time* the change which takes place in the function, divided by the time during which that change has taken place.

Let P Q R (Fig. 4) represent the graph of a time-function, and let us suppose that as the function changes its graph is recorded by a tracing point. When the point arrives at the position P, it is moving along the tangent to the curve at that point. Let us suppose that during the next unit of time the tracing point *goes on* moving along the tangent instead of following the graph along the curve P Q. If $P_1 Q_1$ represent a unit of time, the point will arrive at the position S at the end of the unit of time. Through P draw a line P T parallel to the axis of time. Then the change in the value of the function which would have taken place in a unit of time had the tracing point followed the tangent at P is represented by T S; we define T S as the *instantaneous rate of change* of the function at P, or its rate of change at the instant when its value is $P_1 P_2$. Now, T S is the distance through which the tracing point would have moved *in a vertical direction* had it followed the tangent at P—*i.e.*, T S is the vertical velocity of the tracing point when in the position P. We thus arrive at the result that the instantaneous rate of change of a function is given by the vertical velocity of the point which traces out its graph.

6. The *orthogonal projection* of any point P (Fig. 5) on a straight line A B is defined as the foot P_1 of the perpen-

Digitized by Google

dicular P P_1 drawn from P to A B. The orthogonal projection of any curve P Q R on the straight line A B is obtained by dropping perpendiculars P P_1 and R R_1 from its two extremities P and R on the straight line; $P_1 R_1$ is defined as the orthogonal projection of P Q R on A B. Instead of saying "orthogonal projection," we shall in future use the term "projection" simply. It will be seen that the projection of any curve on the straight line A B merely depends on the position of the extremities of the curve, and is quite independent of its shape. Thus, in Fig. 5, the projection of the curve P Q R is precisely the same as the projection of the straight line P R joining the extremities of the curve.

Through P draw P S parallel to A B. Then P S = $P_1 R_1$ = projection of straight line P R on A B. Also, by definition (Art. 2), $\frac{PS}{PR} = \cos S P R$, so that $P_1 R_1 = PS = PR \cos S P R$. We thus have the following proposition: *the projection of any given straight line on another straight line is equal to the length of that line, multiplied by the cosine of its angle of inclination.* By the "angle of inclination" is meant the angle between the two lines.

7. Returning now to the graph of the function shown in Fig. 4, let us consider the projection on the vertical axis of the point which traces out the graph. As this point passes through the positions P, Q, R, its projection on the vertical axis passes through the positions P_2, Q_2, R_2 respectively. From the explanation regarding the rate of change of a function given in Article 5, it will now be evident that this rate of change is given by the *velocity with which the projection of the tracing point moves along the vertical axis.* This result, which is of great importance, we shall have occasion to use later on.

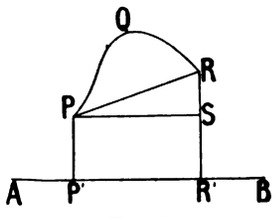

Fig. 5

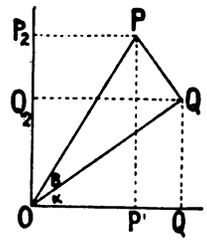

Fig. 6.

8. There are certain relations connecting the sine, cosine, and tangent of a given angle which will be required in what follows, and which we shall now briefly establish. Returning to Fig. 2, we see from its geometry that

$$x^2 + y^2 = r^2,$$

whence
$$\left(\frac{x}{r}\right)^2 + \left(\frac{y}{r}\right)^2 = 1,$$

or
$$\cos^2\theta + \sin^2\theta = 1 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $\cos^2\theta$ stands for "the square of the cosine of θ," with a similar notation for the sine of θ.

Next,
$$\frac{x}{r} \Big/ \frac{y}{r} = \frac{x}{y},$$

or,
$$\frac{\sin\theta}{\cos\theta} = \tan\theta \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Again, by referring to Fig. 2 and remembering the convention regarding signs (Art. 1), the student will readily see that the following relations hold:

$$\cos(-\theta) = \cos\theta \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\sin(-\theta) = -\sin\theta \quad . \quad . \quad . \quad . \quad (4)$$

Next, from Fig. 2 we see that $\frac{x}{r} = \sin\left(\frac{\pi}{2} - \theta\right)$, so that

$$\cos\theta = \sin\left(\frac{\pi}{2} - \theta\right) \quad . \quad . \quad . \quad . \quad (5)$$

Similarly,
$$\sin\theta = \cos\left(\frac{\pi}{2} - \theta\right) \quad . \quad . \quad . \quad . \quad (6)$$

We have finally to establish some formulæ regarding the sine and cosine of the sum and difference of two angles. This is most readily done by making use of the results established in Art. 6 regarding orthogonal projection. Let, in Fig. 6, P Q be drawn perpendicular to O Q, while P P_1, Q Q_1 are both perpendicular to the horizontal axis, and P P_2, Q Q_2 perpendicular to the vertical axis. Projecting first on the horizontal axis, we have

projection of O Q = projection of O P + projection of P Q—*i.e.*, bearing in mind (5) and (6),

$$O Q \cos\alpha = O P \cos(\alpha + \beta) + P Q \sin\alpha.$$

Now, since O Q = projection of O P on O Q = O P $\cos\beta$,

and P Q = projection of P O on P Q = P O $\sin\beta$,

the above equation becomes

$$O P \cos\alpha \cos\beta = O P \cos(\alpha+\beta) + O P \sin\alpha \sin\beta,$$

or,
$$\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta \quad . \quad . \quad (7)$$

In like manner, by projecting on the vertical axis, we establish the equation

$$\sin(\alpha+\beta) = \sin\alpha\cos\beta + \cos\alpha\sin\beta \quad . \quad . \quad (8)$$

Using now equations (3) and (4), and putting $-\beta$ for β in (7) and (8), we obtain

$$\cos(\alpha-\beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta \quad . \quad . \quad (9)$$

$$\sin(\alpha-\beta) = \sin\alpha\cos\beta - \cos\alpha\sin\beta \quad . \quad . \quad (10)$$

All the formulæ given above are of very great importance, and the student is advised to thoroughly master them before going any further.

(To be continued.)

ELECTRIC AND MAGNETIC RESEARCH AT LOW TEMPERATURES.*

BY J. A. FLEMING, M.A., D.SC., F.R.S., M.R.I.

(Continued from page 663.)

Having thus defined our scale of temperature we proceeded to embody the whole of our results in a chart, which is now before you (see Fig. 6), and on which vertical distances represent resistivity, or specific resistance, or the resistance in absolute measure per cubic centimetre of the various metals, and horizontal distances represent platinum temperatures. The

Electrical Resistivity of Pure Metals Annealed.

Metal.	Resistivity in C.G.S. units at 0deg. C.	Percentage increment, 0deg. to 100deg. C.	Atomic volume.

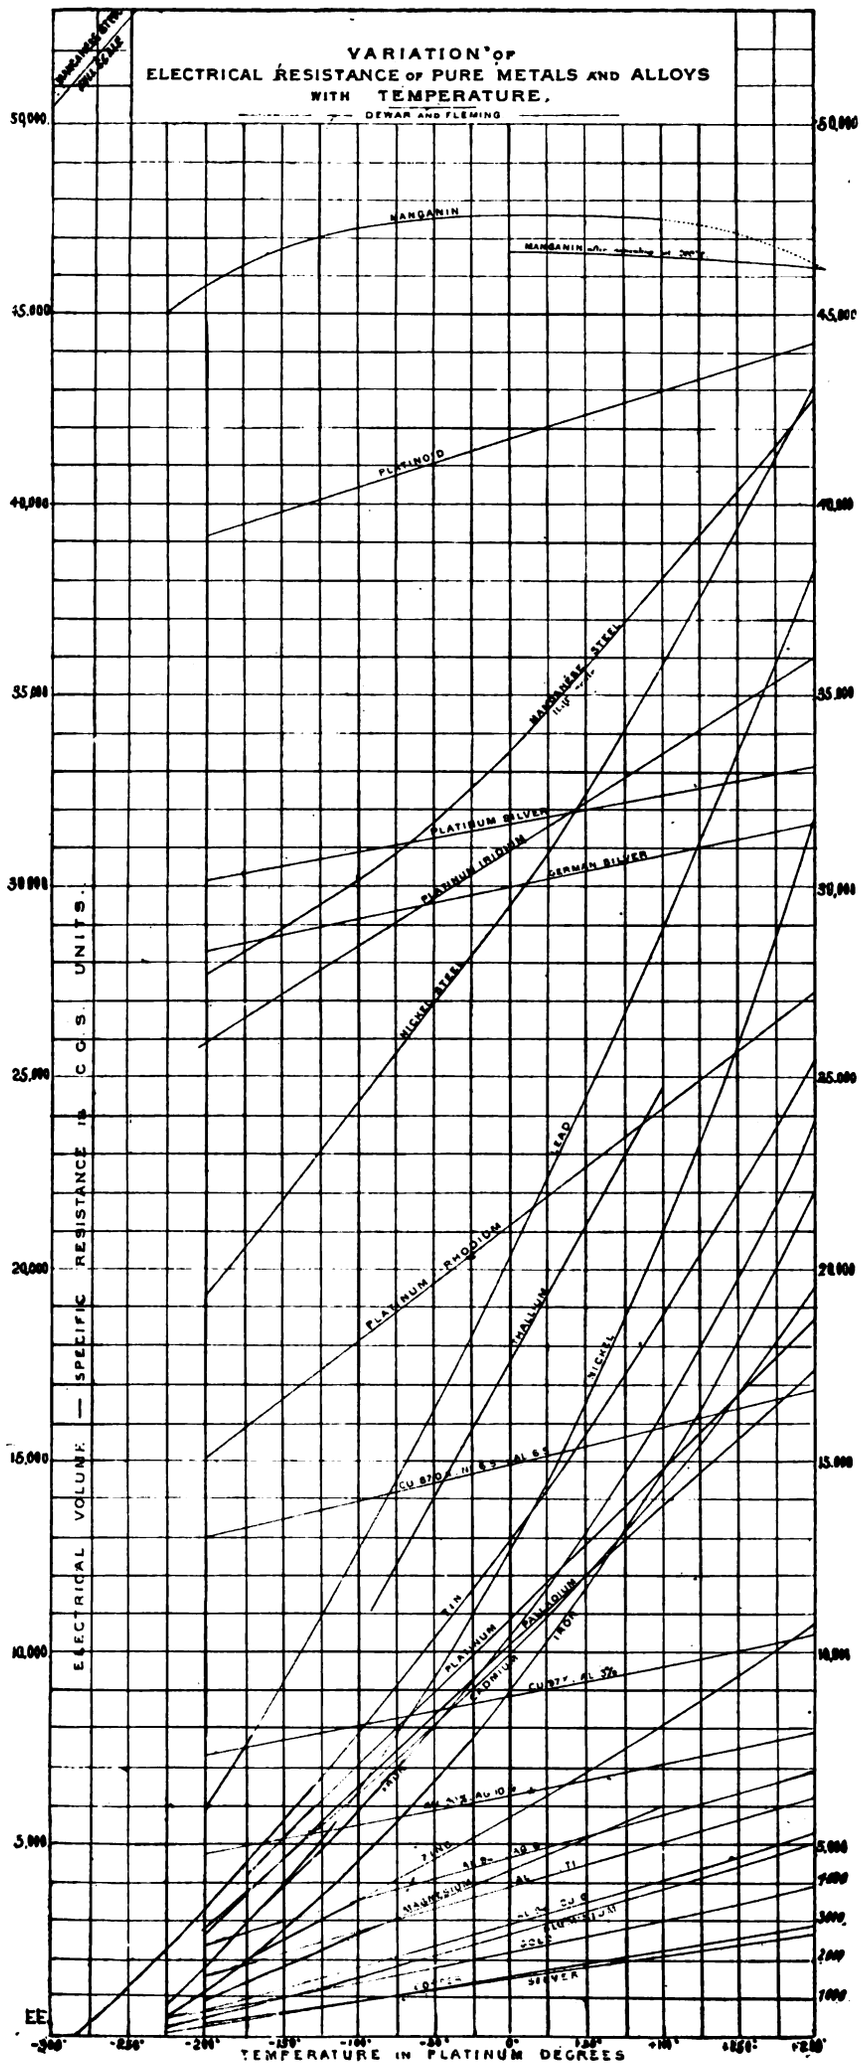

FIG. 6.

curves indicate the manner in which the specific resistance varies with temperature for each substance. The first thing which strikes us on looking at the chart is that the lines for the pure metals all converge downwards in such a manner as to indicate that their electrical resistance would vanish at the absolute zero of temperature, but that no such convergence is indicated in the case of alloys. We have found that the slightest impurity in a metal changes the position of this resistance line. In the next place, note that the order of conductivity is different at low temperatures to that at ordinary temperatures. At 0deg. C. pure silver is the best conductor, but at −200deg. pure copper is better than silver, and the position of mercury is, of course, very different. Again, the lines of some metals are very much curved. The principal magnetic metals, iron and nickel, have lines which are very concave upwards, and this is a characteristic apparently of many magnetic alloys. The mean temperature coefficient of these magnetic metals between 0deg. C. and 100deg. C. is much larger than that of other metals, and the percentage decrease in resistance in cooling them from +200deg. C. to −200deg. C. is greater than in the case of any other metals. The tables before you show the values of the resistivity of pure metal and alloys as found by us (see tables).

It is worth noting, in passing, that these magnetic metals, iron and nickel, have smaller atomic volumes than any other metal, and that, generally speaking, the worst conductors amongst the metals are those that have the large atomic volumes and large valency. Next, turning to alloys, we may make mention of a few general facts with regard to their resistance. If to one pure metal we add a small quantity of any other metal, the result is always to raise the resistance line almost parallel to that of the predominant constituent. Thus, in our chart, the alloy consisting of 6 per cent. of copper with 94 per cent. of aluminium is parallel to the aluminium line but higher up. Three per cent. of aluminium added to 97 per cent. of copper yields an alloy with a resistance line parallel to that of copper, also higher up. When two pure metals are alloyed together in various proportions there is generally some proportion in which the resultant alloy has a maximum resistivity, and except in the case of alloys of zinc, tin, lead, and cadmium with each other the resistivity of the alloy is greater than that of either of its constituent metals. In the case of many well-known alloys the proportions which give high, if not the highest, resistivity are those which correspond to definite and possible chemical combinations of the metals with each other—as, for instance, in the well-known platinum-silver alloy in proportions 33 to 66, which corresponds in proportion with the combination $PtAg_4$; the iron-nickel alloy in proportion of 80 to 20, which corresponds with the combination $NiFe_4$; the platinum-iridium alloy 80 to 20, which corresponds with the combination $IrPt_4$; and the copper-manganese alloy 70 to 30, which corresponds with the compound Cu_2Mn—all of which are, as far as valency is concerned, possible compounds. It is, however, found that very high resistivity generally involves in alloys a want of tenacity and ductility, and when we reach such limits as 100 microhms per cubic centimetre we begin to find the solid alloys becoming less useful on account of this deterioration of their useful mechanical quality.

We have especially studied the electrical resistance at low temperature of a large series of steel alloys containing vary-

Digitized by Google

ing proportions of nickel, aluminium, chromium, tungsten, and manganese in them. The diagram (see Fig. 7) shows the results of these resistance measurements over a range of temperature from – 200deg. to + 100deg. In this diagram the resistance line of pure iron is also drawn, and we see that the effect of adding the other elements of the alloy is always to shift up the resistance line nearly parallel to itself so that the resistance lines of all the iron alloys are nearly parallel to that of the iron line, only the absolute value of all the ordinates is increased. This is equivalent to saying that the effect of the added material is to increase the specific resistance, but not to alter the slope or form of the resistance curve. Amongst these steel alloys there are two or three that are very interesting. A nickel-steel alloy sent to us by Mr. Hadfield containing 19 per cent. of nickel exhibits some very extraordinary properties. Nickel-steel alloys with large percentages of nickel can, as Dr. Hopkinson has shown,* exist over wide limits of temperature in two different physical states, in one of which they are strongly magnetic, and in the other of which they are feebly magnetic; and they pass from the non-magnetic to the feebly magnetic on cooling to low temperatures. Here, for instance, is a sample of the 19 per cent. nickel steel in the non-magnetic condition. If it is cooled in liquid air, we can make it pass instantly into a magnetic condition. In the first state it is fairly ductile and plastic, but in the second state it is very hard and brittle. Moreover, its electrical resistance is permanently altered on undergoing this change. In the non-magnetic state it has a high resistivity of about 81,500 C.G.S. units per cubic centimetre at 0deg. C., but on cooling in liquid air and becoming magnetic it is found to have decreased to about 47,200 C.G.S. units when taken at 0deg. C. It is perhaps more correct to say that this alloy can exist in an infinity of different physical states, because we have found that the lower it is cooled in temperature the lower its resistivity can be made to be when measured again at ordinary temperatures. On heating up the alloy again to a bright red heat, it goes back into the non-magnetic ductile state.

(To be continued.)

THE PHYSICAL SOCIETY.

At the meeting of June 12, Captain Abney, president, in the chair,

Mr. Campbell read a paper **"On the Measurement of Very Large and of Very Small Alternating Currents."** The author advocated the use of air-core transformers for measuring voltages and currents which are neither above or below the range of the instruments available. If an attempt is made to measure the current in the primary of an air-core transformer by observing the voltage on an open-circuit secondary, it is found that the readings depend on the frequency. In order to overcome this difficulty, the author uses a closed secondary with a very high inductance. In this case the primary current is proportional to the secondary current, which latter may be measured by an ammeter. The author has also investigated the case of transformers with iron cores, and of which the inductance of the secondary is large. In the case of a ring transformer with a closed magnetic circuit, if the load on the secondary consists solely of a Kelvin 100-ampere balance of very low resistance, the ratio between the primary and secondary currents is practically constant. With an open magnetic circuit transformer, however, this is not found to be so, as the ratio between the primary and secondary currents varies considerably with the frequency.

Mr. Blakesley said that the author's arrangement could only be used for measuring the current in the primary.

Mr. Griffiths exhibited and described his improved form of resistance box. This has many novel features: (1) It permits of all the coils being compared with one another without the use of standard coils, and with great ease and rapidity;

* See *Proc.*, Roy. Soc., 1890, vol. 47, p. 138.

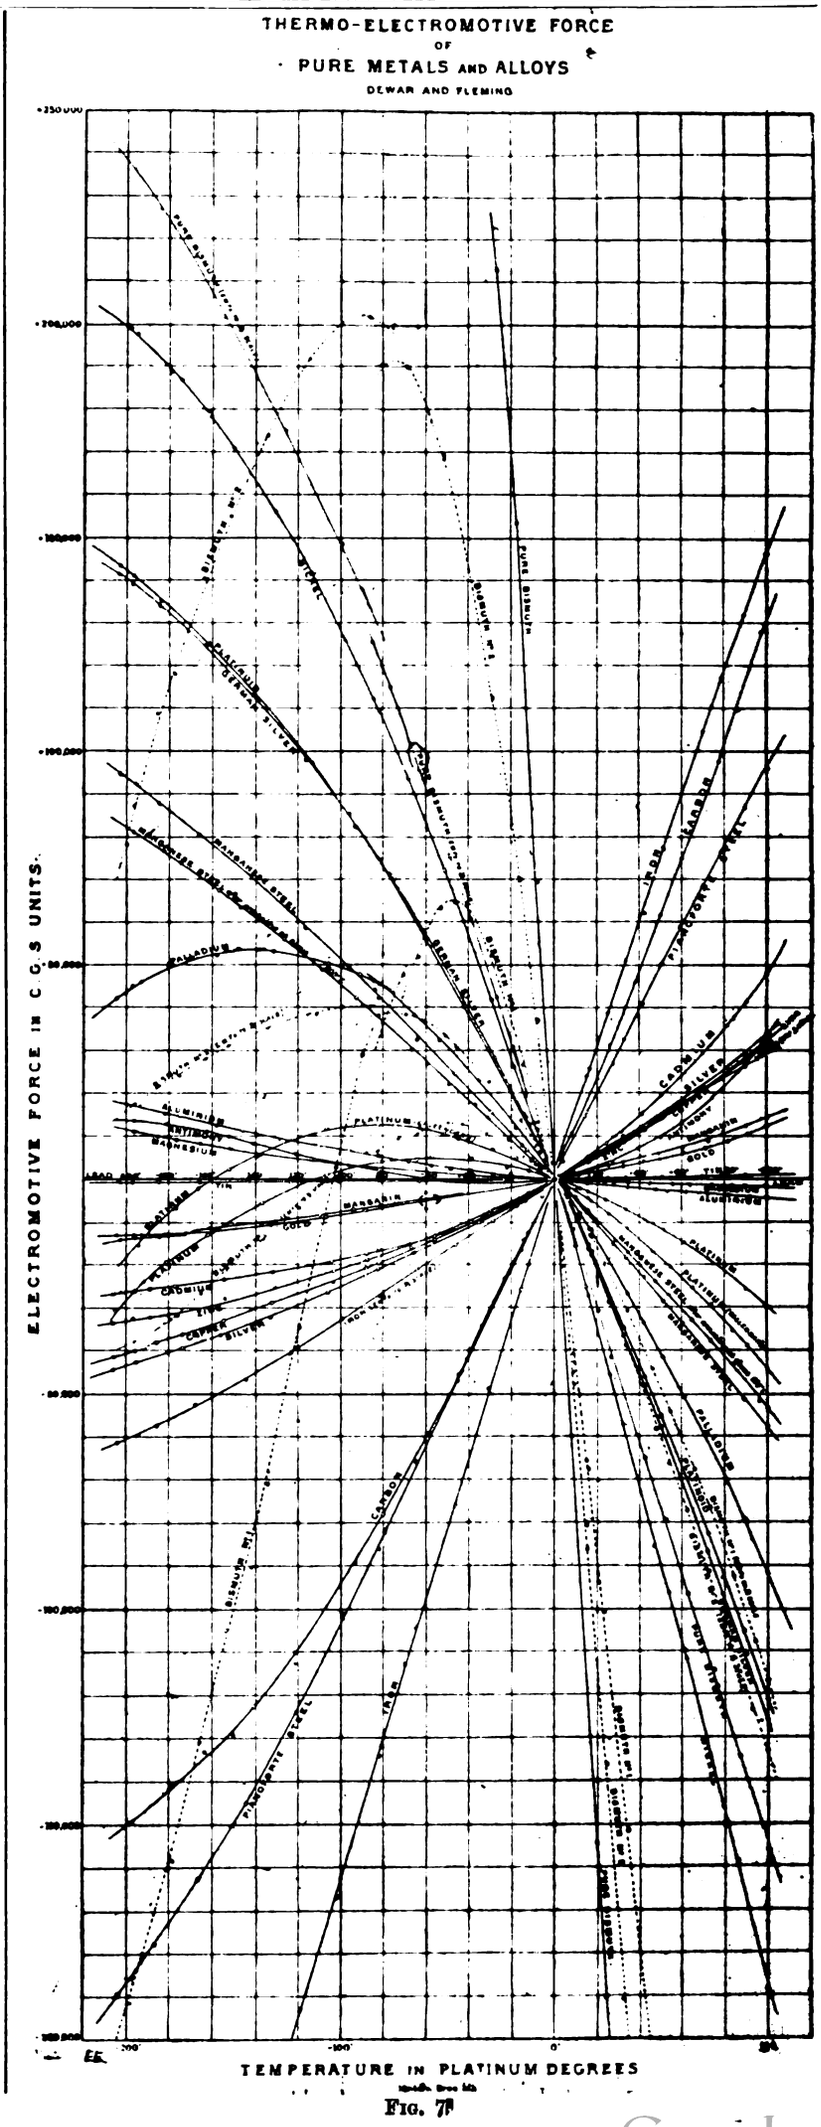

FIG. 7.

Digitized by Google

hence, it is sufficient at any time to compare any one of the coils with a standard to obtain the correction to be applied to all the coils. (2) The bridge wire can be calibrated by means of the box itself. (3) The temperature of the coils can be accurately determined, since they consist of bare platinum silver wire wound on mica and immersed in an oil bath, which bath is kept stirred. (4) The resistance of the leads from the box to the object being tested is eliminated, as well as any error due to a change in this resistance with temperature. (5) The coils are arranged according to a binary scale, and the author claims that it is possible to measure resistances up to 105 ohms to within 0·000001 ohm. (6) All the coils, after being adjusted, have been heated to redness and allowed to cool slowly, so that all strain has been removed from the wire. (7) By having a separate pair of blocks for each plug it is impossible for the insertion of one plug to affect the fit of a neighbouring plug; the plugs themselves are so made that no part of the plug is wider than the top of the hole, and so it is impossible to wear a "shoulder" on the plug.

Prof. A. Gray said that Mr. Griffiths had discovered and remedied all the weak points of the ordinary form of bridge. Lord Kelvin had ordered the paraffin to be melted off the coils of one of his resistance boxes, and it was found that the resistance of the coils altered considerably, owing, no doubt, to the strain to which the wire was subjected when embedded in the solid paraffin. Lord Kelvin had made coils without paraffin, and was specially in favour of the use of the binary scale.

Prof S. P. Thompson said he considered the binary scale the weak point of the author's arrangement, since it did not permit of ratios other than 1 to 1 being employed.

Mr. Campbell asked what current could safely be passed through the coils.

The **Author**, in his reply, said that he believed it to be a great mistake to employ any ratio for the arms other than 1 to 1.

Prof. S P. Thompson read a communication on "**Rontgen Rays**" After describing the various forms of tubes he had made with a view of discovering the best form for the production of Röntgen rays, Prof. Thompson gave an account of the experiments he had made to try and obtain some indication of polarisation. In this connection a large number of crystals have been tested, but the experiments have all given negative results. The author exhibited an electroscope with aluminium leaves, and enclosed in a wire gauze screen to protect it from the influence of outside charges, by means of which he was able to show the discharge of a positively or negatively electrified body by means of the Röntgen rays. A method of obtaining dust figures by the discharge of an electrified body by the Röntgen rays was shown, and some of the results which have been obtained were exhibited. All attempts to obtain true reflection have failed, although it appears as if most bodies, including air, are capable of giving diffuse reflection.

Dr. Shettle, who was announced to give a paper on "**Rontgen Rays,**" explained that he had just discovered that the effects he had intended to describe were due to red light, which had penetrated his dark-room.

Prof. du Bois said that Galitzin had found that Röntgen rays were polarised by tourmaline, a special form of intensifier being necessary to bring out the result in the negative. The behaviour of tourmaline to light waves presented some curious features, for if the wave-length is increased a point is at length reached where the ordinary and extraordinary rays are equally absorbed. For greater wave-lengths the ordinary conditions are reversed. If the Röntgen rays were not homogeneous, the contradictory results obtained by different observers might be due to the fact that they were working with rays which were differently absorbed by tourmaline.

Mr. Swinton said he had tried the effect of heating the cathode and had obtained results which were similar to those obtained by the author. Mr. Swinton further said that he had found that the blue luminescence sometimes observed depended on the size of the cathode. With tubes in which the cathode was almost a complete hemisphere it was impossible to eliminate this blue luminescence.

Mr. Appleyard suggested the performance of the experiments under the surface of a dielectric.

Prof. Gray said he had obtained some indication of regular reflection, but nothing definite.

The **Author**, in his reply, said that it had been found that if the Röntgen rays are reflected from a surface of sodium *in vacuo*, the amount reflected is a minimum for normal incidence and increases at oblique incidence. Comparing this behaviour with that of ultra-violet light, it supports the idea that the Röntgen rays consist of transverse vibrations.

The society then adjourned till June 26.

COMPANIES' MEETINGS AND REPORTS.

WEST AFRICAN TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held last week at the offices, Winchester House, E C., Sir Henry C. Mance, C.I.E., M.I.C.E, presiding.

The **Chairman**, in moving the adoption of the report, said on the last occasion of their meeting their chairman (Sir John Pender) was absent on important business in connection with the general election then going on, and that day, he was sorry to say, Sir John was absent through serious illness. With regard to their work of the year, the gross revenue amounted to £74,333, against £64,761 in 1894, being an increase of £9,572. The total working expenses for 1895 amounted to £17,424, against £17,286; so that, notwithstanding the greater volume of traffic to be dealt with, the efficiency of the system had been fully maintained without any material increase in the expenditure. The loss on exchange was about the same as in the previous year, representing nearly 2½ per cent. on the total share capital of the Company. The directors, taking into consideration the large amount they had been obliged to take from the reserve fund in the past for repairs, especially in 1893, considered it advisable to carry £15,000 to the general reserve fund. They were able to recommend a final dividend of 3 per cent., making, with the interim dividend already paid, a total distribution of 4 per cent. for the year, and carrying £1,760 forward to the next year's account. The reserve fund would now amount to £48,350, and it would be seen that the Company had over £43,000 actually invested at the present moment in first-class securities.

The report was carried unanimously.

CONTINENTAL METROPOLITAN TRAMWAYS COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Wednesday at the Cannon-street Hotel, Mr. B. H. Van Tromp in the chair, to consider a resolution approving a provisional agreement between the Company and the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston, dated the 15th inst., and empowering the directors "to do all things needful for carrying the same into effect."

The **Chairman,** in moving the adoption of the resolution to this effect, said that the Thomson-Houston Company, which was an offshoot of a large and important general electric company in New York, had established themselves in France as a French company, and had purchased the tramways at Havre and Rouen, which they had converted into electrical tramways. They greatly desired to begin operations by a grand movement in Paris, and the subject was mentioned casually to one of their directors about six weeks ago. On the 17th ult., however, they received a letter from this French company, dated from Paris, in which they made an offer of £320,000 for this Company's undertaking, the French company to take the profits as from December 31 last. After discussing the offer it was declined, and he stated to two representatives of the Thomson-Houston Company that what they wanted for the undertaking was in round figures about £400,000. On the 20th ult. the directors received a letter in which £358,000 was offered for the undertaking. This proposal was discussed by the directors, and he telegraphed to Paris that the lowest sum they could advise the shareholders to take was £392 800 and the profits for the six months up to the 30th inst., and the French company must take over the bonds or obligations entered into in Paris, under which this Company had to pay back £10,000 a year until the discharge of the bonds in question, on which £100,000 was still due The French company were, therefore, practically giving them nearly £500,000 for their undertaking. On the morning of the 22nd ult. he received a telegram from Paris accepting the terms of his telegram. The question was one entirely for the shareholders, and the directors had no interest whatever in the matter which was not absolutely the shareholders' interest, but the directors unhesitatingly recommended the shareholders to approve the agreement. If, as suggested in the directors' circular, the preference shareholders received £5. 10s. a share, the preferred ordinary shareholders £5, and ordinary shareholders £3, £2,000 more than the purchase-money would be absorbed. They had, however, about £2,000 in London invested, in addition to the current half-year's earnings, which he estimated at £6,000 at least, and there would also be the interest which was to accrue on the purchase-money as from the 30th inst. The agreement provided that the money was to be paid on October 1 next, but it might be paid before, and if so the directors would have to invest it in the best way they could until the shareholders decided on the way of dividing it.

Mr. George Richardson seconded the motion, which, after discussion, was carried unanimously.

On the motion of **Mr. Concanon,** seconded by **Mr. Powell,** a resolution was passed requesting the directors to invite three preferred shareholders, two preferred ordinary shareholders, and two ordinary shareholders to confer with them as to the distribution, the number of shareholders invited to be increased if the directors thought it necessary.

ELMORE'S FOREIGN AND COLONIAL COPPER DEPOSITING COMPANY.

The seventh annual ordinary general meeting of Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited, was held on Wednesday at Broad-street-avenue, E.C., Mr. F. L. Rawson presiding.

In moving the adoption of the report, the **Chairman** said the profit and loss account was given for two years instead of one year, as 12 months ago the Company was in a very difficult position—from which it had satisfactorily emerged—and they were not then in possession of the books Now, however, the ordinary creditors of the Company had been reduced from £8,440 to a little over £2,000, nearly the whole of which was due to the directors. The result of the appointment of the receiver had been that, by getting a reduction in settlement of accounts with the ordinary creditors, they had made a net profit of £698. 10s. 9d. With regard to reduction on investment through sale and surrender of securities—£39,864—the principal items were 8,000 German

Digitized by Google

shares surrendered, £16,000; exchange of German debentures into preference shares, £10,614 (this exchange ought ultimately to mean a profit to the Company); loss on sale of German Elmore debenture stock and shares, £11,644. The amounts paid for carrying on the Company, with the exception of the amounts paid for the maintenance of the patents, had been but nominal. Nearly all the work was done by the directors, and now that the Company has been got into safety again and the work of the directors was not so onerous, it was proposed to reduce the amount of the directors' fees. The progress of the companies was comparatively slow, but was sure, and only want of money had prevented large extensions of the business. Mr. Rawson subsequently referred to the Dumoulin system of deposition as follows: "I am sorry to say that I have been unable to obtain any authentic particulars of this system, other than the *ex parte* statements of the promoters. On looking into the patent, I have come to the conclusion that it is an absolutely worthless document. The inventor claims that by coating the surface of the copper as it is being deposited with grease, he gets a better tube, as the molecules of copper are not deposited on the projecting molecules first deposited, which are covered by the grease; but they are deposited in the interstices until they become level with the projecting molecules. I am certain that his process would work better without any of this grease, which can be no improvement, and in my opinion the improved result obtained over ordinary deposited copper is simply due to the fact that he uses something in the bath which acts as a rubber or burnisher. It was originally well known to the Elmores that even such a substance as a piece of leather or felt pressed against a revolving tube will considerably improve the quality of the deposited copper, and this is fully covered in the Elmore patents. There is the objection, however, that the copper continually wears away any soft substance, the particles remaining in the bath, where they do harm. With the Elmore process as now worked the agate which acts as a burnisher is so hard that there is no objection on this score. If the Dumoulin improvement is due to the burnishing effect and not to the grease, then it is unquestionably an infringement of the Elmore patent."

Mr. J. Shurmen seconded the adoption of the report.

Mr. Julius Runges said there were several things about the balance-sheet which he did not like, and moved that the amounts be received but not adopted, and that a committee of shareholders be appointed to investigate the affairs of the Company and report to an adjourned meeting.

Mr. Boyer seconded this amendment; but it was not pressed, and in the end the original motion was carried with two dissentients.

ELECTRIC AND GENERAL INVESTMENT COMPANY, LIMITED.

The seventh ordinary general meeting of the shareholders was held yesterday (Thursday) at Winchester House, E.C., Mr. George Herring, chairman of the Company, presiding.

The report and balance-sheet were, on the motion of the **Chairman**, adopted, and a dividend making a total of 20 per cent. for the year was declared. The holders of founders' shares (£5) receive a dividend of £20 per share. The dividends are payable on June 19.

The retiring directors, Mr. George Herring and Mr. B. H Van Tromp, were re elected, and the auditor, Mr. G. T. Rait, was also re elected.

The usual votes of thanks terminated the meeting.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ecija (Spain).—The Municipal Authorities of Ecija want tenders by July 2 for a system of electric lighting for the town.

Benevento (Italy).—A concession for installing and working the electric lighting of the town of Benevento is open to be tendered for up to June 20.

Bucharest.—The Municipality want tenders by July 1 for the electric lighting of a portion of the Boulevard Coltzea. The estimate is about £3,680.

Utrera (Spain).—Tenders are wanted by the Municipal Authority of Utrera for the installation of electric lighting. The last date for receipt of tenders is July 1.

London, S.E.—Tenders are required for complete installation of electric lighting. For particulars apply by letter to Mr. H. Freeman, 44, Knatchbull-road, Camberwell, S.E.

Prestwich.—Tenders for putting into thorough repair the existing telephone system and electric bells at the county asylum, Prestwich, are invited. Full particulars on application at the asylum.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31.

Leeds.—The City Council invite tenders for two steel boilers and accessories for the proposed tramway electric generating station. Specifications, forms of tender, and particulars may be obtained (on payment of a deposit of £2. 2s., which will be returned on receipt of a bona fide tender) at the city engineer's office, Municipal Buildings. Tenders, endorsed "Tender for Boilers," to be sent to the town clerk's office before 12 noon on 22nd inst.

Zulz (Germany).—Tenders are wanted by June 22 for the supply of 650 telegraph poles for the Neustadt and Gogoliner line. Application to Die Bauleitung der Neustadt-Gogoliner Eisenbahn, Zülz O.-S.

Spandau.—Tenders are wanted at the Royal Small-Arms Factory for 900 incandescent electric lamps by July 17. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21), Spandau.

Cazeres-sur-Garonne (France).—Tenders will be received up to June 28 for electric lighting and water supply work and buildings. The estimate is about £2,043. Applications should be made to the Mairie, Cazères-sur-Garonne, Haute-Garonne.

Brussels.—Tenders will be received shortly (the exact date is not yet announced) at the Brussels Bourse for the material and work necessary to start an electric lighting installation at the fifth section of the central locomotive construction works at Malines.

Paris.—Tenders are wanted by the French Government Telegraphic Department for the supply of about 125 tons of galvanised iron wire, 3,000 cross-pieces (iron), and 100,000 screws and various accessories. Particulars are obtainable at Rue de Grenelle 103, Paris, and application for permission to tender must be made before June 15. Tenders must be in by June 25.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Huddersfield.—Messrs. Learoyd Bros. and Co invite tenders for the wiring of the Trafalgar Mills. Copies of the specifications and general conditions can be obtained from Messrs. Shepherd and Watney, 71, Albion-street, Leeds, on payment of a cheque for £1. 1s, which will be returned on receipt of a bona fide tender. Tenders, endorsed "Electric Lighting," must be addressed and delivered to Messrs. Learoyd Bros and Co., Milnsbridge, Huddersfield, by 12 noon on July 7.

Colchester.—Tenders are required for the supply and fixing of insulated conduits, cables, switch and fuse boards, and all sundry fittings and materials for installing the electric light in the Albert School of Science and Art. Specification, with forms of tender, can be obtained from the borough surveyor on payment of £1. 1s., which sum will be returned upon receipt of a bona fide tender. Sealed tenders, properly endorsed, to be sent by 4 p.m on 23rd inst. to Mr. H. Goodyear, borough surveyor, Colchester.

San Juan (Porto Rico).—H.M. Secretary of State for Foreign Affairs has received from H.M. ambassador at Madrid a copy of a Spanish Royal Order which has appeared in the *Gazette* inviting tenders for the construction and working of a telephone system in San Juan de Puerto Rico. A deposit of 800dol. must accompany each tender which will be considered on August 10. The copy of the Royal Order may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Burnley.—The Corporation invite tenders for the supply and delivery at their electric lighting station, Burnley, of armoured concentric underground cables. Specification, schedule of quantities, and form of tender may be obtained on application to Mr. W. R Wright, borough electrical engineer, on payment of £1. 1s., which will be returned on receipt of a *bonâ fide* tender. Sealed tenders, endorsed "Tender for Cables," and addressed to the Chairman of the Electric Lighting Sub-Committee, Town Hall, Burnley, must be delivered on or before the 24th inst.

Cardiff.—The Corporation invite tenders for the construction, supply, delivery, and fixing of an evaporative condenser and concentric cables. Specifications may be obtained on application to Mr. W. Harpur, M.I.C.E., borough engineer, Town Hall Cardiff. Sealed tenders, addressed and endorsed "Tenders for Electricity Works," must be left at the office of Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by 25th inst. A fee of £1. 1s. will be charged for a copy of either of the specifications which will be refunded on the return of the specification accompanied by a bona fide tender.

Inverness.—The Highland Railway Company require tenders for the supply of (20) galvanised telegraph wire, (46) telegraph instruments and fittings, (47) telegraph construction material, etc., from July 1 next to June 30, 1897, delivered free of all charges *viâ* Dunkeld, at the storehouses, Inverness. Tenders, properly endorsed, sealed, and addressed to the directors, must be lodged with Mr. Wm. Gowenlock, secretary, Inverness, by 20th inst. Separate forms of tender will be provided for each contract; parties are therefore requested to specify the particular contract or contracts in respect of which they propose to submit tenders. Patterns can be seen at the stores warehouses, Inverness, but cannot be sent away for inspection.

Leeds.—The City Council invite tenders for an electrical installation sufficient for the working by the overhead system of haulage, a double track of tramway seven miles long. The work will be divided into the following contracts: (1) poles for supporting trolley wire; (2) underground conduits and con ductors; (3) trolley wire and attachments; (4) motorcars; (5) accumulators and switches; (6) steam-engines; (7) dynamos, switchboards, and accessories. Tenders, endorsed with the number of the contract, must be sent in, addressed to the Town Clerk, Town Hall, Leeds, by June 22. Particulars, plans, forms of tender may be had (on payment of a deposit of £2. 2s. for each

Digitized by Google

contract, which will be returned on receipt of a bona fide tender) from the City Engineer, Municipal Buildings, Leeds; or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, S.W.

Hampstead (London).—Tenders are wanted for the extension of the electric lighting station in the parish stoneyard, Lithos-road, Finchley-road, N.W., for the Vestry of St. John, Hampstead. Drawings and specification can be inspected, and bills of quantities and form of tender obtained, on application to Mr. Arthur P. Johnson, vestry clerk, Vestry Hall, Haverstock-hill, Hampstead, N.W., between 10 a.m. and 4 p.m., and upon payment of £2. 2s., which will be returned if a bona fide tender is sent in. The person or firm whose tender is accepted will be required to enter into a written contract and to provide two sureties for the performance of contract. The expenses of contract and bond are to be paid by the contractor. Sealed tenders, endorsed "Tender for Extension of Electric Lighting Station," must be delivered at the vestry clerk's office by 4 p.m. on 25th inst.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following: (*a*) the amount of capital which the applicants are prepared to subscribe; (*b*) the system which it is proposed to establish; (*c*) the mileage of lines to be laid; (*d*) the fares to be charged; (*e*) the frequency of the service; (*f*) the length of the license required by applicants; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about 12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

RESULTS OF TENDERS.

Bradford.—The accepted tender for the works required in the installation of electric lighting at Cliffe-road destructor works, for the Corporation, was that of Mr. G. A Steinthal, Piccadilly, Bradford.

Kensington (London).—At the statutory meeting of the Royal Palace Hotel Company it was stated that the contract for the electric wiring has been given to Messrs. Dalston, and the ironwork to Shaw and Co.

Islington.—The order for the alternators for the extension to the Islington electricity works has gone to the Ferranti Company, from whom the Vestry have just ordered two 300 kilowatt Ferranti flywheel alternators.

Tunbridge Wells.—The following tender has been accepted for various machinery and fittings at the electric light station, for the Town Council: Babcock and Wilcox, two large boilers at £543 each; small one, £264; and feed-water heater, £147.

Correction.—By inadvertence the estimate of the consulting engineer, Mr. G. R. Peers, Deansgate Manchester, for the cost of installing the electric light in the Rochdale free library was given in this column last week as if it had been an accepted tender. As a matter of fact tenders for the work have yet to be received.

BUSINESS NOTES.

Newington.—The Vestry have appointed a special committee for electric lighting.

Nottingham.—There has been a trades union meeting of workmen engaged in various branches of the electrical trades.

Kidderminster.—In the House of Commons last week the Kidderminster and Stourport Electric Tramway Bill was read a third time.

Govan.—The Commissioners' provisional electric lighting order having expired, a report on the position of affairs will be presented at the next meeting.

Hudson River Tunnel.—A bondholders' meeting at Cannon-street Hotel has approved the new scheme for carrying out the New York Hudson River tunnel.

Kensington (London).—The Vestry Committee have approved the plans for extensions of the Kensington and Knightsbridge Company and the Notting Hill Company.

Wrexham.—It is stated that the Lighting Committee have decided to recommend the Town Council to apply for a provisional order for supplying electric light and power.

Incandescent Gas.—The appeal recently lodged by the Incandescent Gas Company against Mr. Justice Wills's judgment in favour of the Sunlight system has been withdrawn.

The British Motor Company.—It is stated that this Company is about to announce a further interim dividend of 30 per cent., in addition to the 10 per cent. that was paid a few weeks ago.

Torquay.—A Local Government Board enquiry is shortly to be held into the question of electric lighting.

Personal.—Mr. J. C. Howell, of 24, Queen Victoria-street, E.C., informs us that he has ceased to represent Messrs. Crompton and Co., Limited, of Chelmsford, in South Wales and elsewhere.

Westralian Electric Lighting and Supply Company, Limited. This Company announces that the following cablegram has been received from Coolgardie: "Lighting formally opened June 6."

Newmarket.—At a meeting of the Urban District Council a motion to rescind the resolution of the Council on March 9 last with regard to adopting the electric light was lost by eight votes to four.

West Coast of America Telegraph Company.—The coupons due 30th inst. on the debentures of this Company will be paid by Messrs. Barclay and Co., Lombard-street, and should be left three days for examination.

Rochdale.—The consulting engineer for the installation of the electric light at the free library is Mr. G. R. Peers, and plans and specifications necessary for putting the work out for tender have been prepared by him.

Dundee.—The estimated income in the electricity department of the Town Council, where it is proposed to grant 5 per cent. discount on prompt payment, is £5,225 and the expenditure is put down at £4 493. 14s. 4d.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending June 14 amounted to £1,176, as compared with £1,268 in the corresponding week of the previous year, being a decrease of £92.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending June 13 were £2,146. 3s. 11d., compared with £1,877. 1s. 1d. for the corresponding period of last year, being an increase of £269. 2s. 10d.

Bearpark (Durham).—The village has recently been provided with the electric light, and to commemorate the completion of the installation the parish councillors have been entertained at supper by the engineers, Messrs. Cox-Walkers, of Darlington.

Hammersmith.—The Electric Lighting Committee of the Vestry have accepted the tender of Messrs. Leslie and Co., of Kensington-square, for the purpose of carrying out the following work: boiler-house and engine-house £5,281, and shaft £1,950.

Camberwell (London).—The Electricity Committee have reported that the modifications introduced into the order of the County of London and Brush Provincial Electric Lighting Company do not affect the principle of the Vestry's recommendations.

Hermite International Electrical Sanitation Company, Limited.—This Company has been floated to deal with the several inventions, patents, and patent rights collectively, known as the Hermite patents, for bleaching, electrolysing, disinfecting, purifying, sanitary, and other processes.

Fort-William.—The works of the electric lighting company are in an advanced state, and it is expected they will be in use on July 1. An electric storage station has been erected at the head of Bank street, and at present the overhead wires are being run and the cable laid through the town.

Chester.—The Town Council have opened a credit for the Electric Lighting Committee at the bank to enable the committee to pay the certificates to be given from time to time by Prof. Kennedy, pursuant to the contract with Thomas Parker, Limited. Five thousand pounds will be placed to the credit of the committee.

City and South London Railway.—The returns for the week ended June 14 were £877, compared with £862 for the corresponding period of last year, being an increase of £15. The total receipts for the half-year terminating as above were £22,342, compared with £22 299 in the same period of the preceding year, being an increase of £43.

Alternate-Current Transformers.—Messrs. Johnson and Phillips remind us that they are the absolute and sole proprietors of all Mr. Gisbert Kapp's patents for transformers, and point out that manufacturers claiming to put on the market transformers made from Mr. Kapp's designs render themselves and their clients liable to action at law for infringements of patents.

Ostend.—A sum of about £24,000 has been placed upon the estimates of the current year in connection with works projected by the late Colonel North on the Ostend coast. The Belgian Government, which is amply secured, has undertaken to intervene in the establishment of electric works, etc., conceded to Colonel North by the convention of January 25 of last year.

Eccles.—The Local Government Board enquiry into the application of the Corporation for sanction to borrow £20,000 for electric lighting was resumed last Tuesday. This time there was great opposition on account of the increase to the rates which would ensue from the adoption of the scheme. The Corporation have several other schemes in hand and under consideration.

Paddington.—At a meeting of the Baths Commissioners a letter was read from the Metropolitan Electric Supply Company informing the Commissioners that there would be a reduction in future in the price charged to them for the electric current used at the baths. The effect of this communication will be that 6d. will have to be paid for the amount for which hitherto 7d. has been charged.

Tourist Guide to the Continent.—We have received a copy of the Great Eastern Railway Company's guide-book to the Continent for the current year. This is the seventeenth annual issue, and we can only repeat what has been said before—that the book is most useful and very concise. Among its fresh features are a

Digitized by Google

series of Continental maps, a chapter upon cycling routes in Holland, Belgium, and Germany, etc.

Cowes.—At a meeting of the Council, with regard to the application of the National Telephone Company to lay wires to Osborne, it was resolved that permission be given provided the wires are laid underground and in such a position as the surveyor may direct, that a deposit of £10 be left with the surveyor till the roads were made good to his satisfaction, and that plans be supplied.

Ashbourn.—Mr. John Shaw, jun., who is officially associated with the scheme for an electric railway from Derby to Ashbourn, has written to the Rural District Council stating that as soon as the Light Railways Bill has passed through Parliament the scheme will be again submitted to the public for approval. The Council declined to discuss the scheme until the Light Railways Bill had received the sanction of the Legislature.

Newport (I W.).—At a meeting of the Isle of Wight Highways Committee, a letter was read from the National Telephone Company asking permission to erect poles and wires by the side of the highways for the purpose of providing telephonic communication between the various island towns. It was agreed to grant permission where the roads were 15ft. wide, 3s per mile to be charged as a kind of acknowledgment rental, instead of 1s as offered by the company.

Dundee.—At the annual meeting of the directors of the Royal Lunatic Asylum it was moved that a remit be made to the Committee of Management to have the asylum and Gray House lighted with electricity. From enquiries which had been made it was found that the cost of the installation would be about £1,500, or, at the outside, £2,000. It was agreed that estimates should be submitted to a special meeting of the Board to be held to consider the whole subject.

Mitchelstown.—At the meeting of the Guardians a deputation attended in reference to a scheme to light the streets by electricity. Mr. Roche said it was proposed to borrow a sum of £330 from the Board of Works for the erection of plant. It was originally intended to have 36 electric lamps, but it was expected that they would be able to reduce this number to 25 The cost would be about £1 per lamp annually. A resolution was carried that application be made for the necessary powers.

Wolverhampton.—The Town Council have instructed the Public Works Committee to consider the advisability or otherwise of the Corporation exercising on the expiration of the term of 21 years mentioned in Section 43 of the Tramways Act, 1870 their power under such section to purchase the portion of the undertaking of the Wolverhampton Tramways Company within the borough The committee will also consider the question as to who shall work the tramways, and what system shall be adopted.

London Extensions.—The Highways Committee of the London County Council have passed notices from the Vestry of St. Pancras of intention to lay a telephone wire from the Gray's-inn-road electric lighting sub-station to that in Well-street; from the County of London and Brush Provincial Electric Lighting Company to lay low-tension mains in Myddelton-street, Clerkenwell; and from the Metropolitan Electric Supply Company of intention to lay mains in Great Turnstile from Newman's-row to Holborn.

Portsmouth.—At a meeting of the Town Council one of the clauses in the Electric Lighting Committee's report recommended that an engine of 1,000 h.p. should be ordered from Messrs. Ferranti at a cost of £6,200. In addition, there would be the cost of the fittings and connections, and it would be necessary to provide two larger feeders for supplying the electric current in different directions. It was further recommended that application should be made to the Local Government Board for sanction to borrow the sum of £10,000. The report was adopted.

Paisley.—At a meeting of the Electric Lighting Committee it was agreed to recommend acceptance of the Brush Company's offer for wiring the town hall at £844, provided the specimens of wire submitted are satisfactory. At a subsequent meeting a number of offers of ground for a central electric lighting station were laid on the table. The Town Council at the last meeting decided to leave over the consideration of these until an engineer has been appointed to advise as to the most suitable site, and that a resident engineer be at once advertised for.

Ashton-on-Mersey.—The Urban District Council have decided that Mr. Slater and the law clerk (Mr. Briggs) shall see the solicitors of the Altrincham Electric Supply, Limited, and intimate that the Council are prepared to agree to the provisional order, and will enter into an agreement giving the Council similar action in the Bucklow Rural District Council. If they decline to do so, the law clerk is to be empowered to write to the Board of Trade with reference to the provisional order, in so far as regards the breaking up and repair of roads and streets.

Fulham.—At a meeting of the Electric Lighting and Dust Destructor Committee of the Vestry Mr. F. H. Medhurst brought up a report in which he estimated that the cost of a destructor would be £12,800, destroying 22 000 loads at 1s. per load £1,100 The combined scheme for providing the electric light and a dust destructor was estimated to cost £54,500, and the net annual profit on the combined scheme was £1,659. 11s. The committee eventually decided to interview Mr. Medhurst with a view of seeing other destructors at work before they decided one way or the other.

Barrow.—At the County Council meeting letters were read from the general manager of the Furness Railway and the managing director of the Naval Construction and Armaments Company with regard to electric lighting. The borough engineer was instructed to see the general manager of the Furness Railways in reference to his letter. It was resolved that the town clerk write the liquidator of the Barrow Tramways Company asking whether, in the event of an installation being laid down the company would be prepared to take electricity for the purposes of working their tramways.

The City and Guilds of London Institute.—In response to an advertisement recently issued by the Executive Committee for a professor of mechanical engineering and applied mathematics at the Technical College, Finsbury, 17 applications have been received. The position has been rendered vacant by the appointment of Prof. Perry to the Royal College of Science, South Kensington. The salary attached to the position is £600 per annum, and the appointment will date from September 29. The Executive Committee will deal with the applications in the course of a few days, and the result of their investigation will be duly announced.

Grimsby.—At the meeting of the Town Council, Alderman Dobson moved the adoption of a recommendation of the Lighting Committee that a new dynamo for the electric lighting installation of the town hall be purchased at once, and that the tender of Messrs. P. R. Jackson and Co, for a dynamo with an output of 110 volts, at a cost of £144. 10s., be accepted. Alderman Evison seconded the proposition. Mr. Moss moved, as an amendment, that the matter be referred back to committee. He understood in the first instance that the new dynamo was to be placed alongside the present one. Mr. Wright seconded the amendment, which was carried.

Cardiff.—At a meeting of the Lighting Committee a letter was read from the electrical department of the General Post Office London, with regard to the lighting of the new post office at Cardiff The authorities are preparing to light the Cardiff office by electricity, and desired to know the lowest rate at which they could be supplied by the Corporation. A low estimate fixed the consumption at 60,000 units a year, and it was likely to amount to 80,000 units. Mr. Appleby stated that it would be necessary to ascertain whether it would be all day running or all night running before a price was given. Mr Appleby's report showed that there was a steady increase in the electricity used for lighting purposes.

British Motor Carriage and Cycle Company, Limited.—This Company was registered on June 5 by Lumley and Lumley, 37, Conduit street, W., with a capital of £200,000 in £1 shares. Object: to acquire, by purchase or otherwise, patents for any description of motors, cycles, carts, wagons, vehicles, ships, boats, launches flying machines, carriages, etc., and to use, exercise, develop, grant licenses in respect of, and turn to account the same, and to carry on in all or any of their respective branches the businesses of motor cycle and carriage manufacturers; also as electricians and electrical engineers, machinists, fitters, founders, millwrights, smiths, wire drawers tube makers, metallurgists, saddlers, etc.

Ayr.—At a meeting of the Town Council Mr. E. G. Pink, burgh electrical engineer, in his monthly report stated that the plant continued to run as well as ever. The mains had been finally tested and taken over and the contractors' work was completed. With the exception of the sub station they were still working on Swinburne and small Fowler transformers, which might give trouble at any time. The new street lamps supplied by Messrs. Fowler were an improvement. At present, however, they were taking too much current, and they were waiting the arrival of the new choking coils from Leeds to reduce the current to 16 amperes. The Wallacetown lamps could not be fixed at present as the transformers were required at the works for testing.

Fareham.—At a meeting of the Urban District Council it was recommended that 17 arc lamps should be placed in High-street and West-street, that earthenware conduits should be used, as proposed by Mr. Manville, and placed under the pavement. The report also recommended that second hand plant should be purchased. The cost of carrying out the work and the purchase of the plant was estimated at £2,800, to which was added a sum of £200 for the piece of land adjoining the electric light works. It was also recommended that the Council should at once enter into a contract to purchase and fix all the plant as soon as possible, and should apply to the Local Government Board for sanction to obtain a loan of £1,900 for the carrying out of the work. The report was adopted.

Watford.—A long discussion took place at the Urban Council meeting with regard to the electric lighting question, and ultimately the following resolution was passed: "That this Council is of opinion that it is desirable to issue advertisements in the electrical newspapers seeking applications from eminent consulting engineers to advise the Council in the preparation of their application for a provisional order from the Board of Trade, as to the best system to be adopted, and generally as to the cost of the undertaking, the area to be lighted, and also as to its probable development Engineers to state their fee for such preliminary report and advice, the Council giving no guarantee as to subsequent employment. The engineer to advise the Council as to whether they control the powers in their own hands or dispose of them to a company or otherwise."

Appointments Vacant.—The Technical Instruction Committee of the borough of West Bromwich invite applications for the post of assistant lecturer and demonstrator in metallurgy, chemistry, and physics. Salary, £100 per annum The teacher appointed must be specially qualified for teaching metallurgy. Applications (accompanied by copies of not more than four recent testimonials) to be sent by 30th inst. to the secretary, Mr. T. Gilbert Griffiths, from whom further particulars may be had on application. Canvassing for the appointment is not permitted.—The Burgh of Paisley are advertising for a resident electrical engineer to design

Digitized by Google

and superintend the laying down of a central installation and to manage the same after completion. Salary to commence with £200. Applications, with testimonials, to be lodged with the town clerks on or before July 1. Canvassing members of the Council is prohibited.

Bingley.—At a meeting of the District Council the chairman of the Gas Committee recommended the adoption of electric light. He had been in communication with the directors of the Leeds and Liverpool Canal Company, who were prepared to erect the necessary plant at the bottom of the Three Rise and Five Rise locks, and supply the town with electricity, the Council bearing the cost of distribution. The directors believed that they could produce at those points electricity equivalent to 20,000,000 cubic feet of gas, a quantity which he found was consumed by the mills, the Midland Railway Company, and the hotels every year. Therefore, if those places could be induced to take the electric light it would relieve the Council from the necessity of making costly extensions of the gasworks. He did not think there was any doubt but that by this means electricity could be produced cheaper than by any other way. He could not tell them what price it could be retailed at per unit, but it would not have to be more than the Bradford price. The motion was adopted without discussion.

Manchester.—A new electric light installation has been established by the Ship Canal Company at Trafford Bridge. The installation which has been displaced was of merely a temporary character, power being supplied by no less than three different generating stations. On the recommendation of Mr. Hunter, the company's engineer, Mr. Fawcus, of the Manchester Edison-Swan Company, was consulted, and under his advice the new installation has been carried out. There are two sets of compound inverted cylinder vertical engines of 100 h.p., made by Mr. Goodfellow, of Hyde, and two sets of 30-h.p. engines made by Messrs. Browett and Lindley, of Patricroft, the alternators and exciters being supplied by Messrs. Baxendale and Co., of Miller-street, Manchester. The lighting area includes the Manchester and Salford Docks and the locks at Mode Wheel, together with the road to the locks. There are 66 arc lamps, continuous current, 28 alternating arc lamps of 2,000 c.p. each, 360 incandescent lamps of 50 c.p. each, 100 of 32 c.p., and 28 of 16 c.p. Inside the sheds incandescent lamps alone are used.

The London Tramways Question.—The secretary of the County of London Tramways Syndicate, Limited, has addressed a letter, dated June 15, to the clerk of the London County Council, in the course of which he states that, "Inasmuch as the requirement on the part of the County Council of a 14 years' lease would involve injury to the companies and prejudice to the travelling public without sufficient benefit to the ratepayers, my directors feel that it would be unworthy of the spirit in which they entered upon their negotiations to propose the modifications indicated in your letter now under acknowledgment. If, however, contrary to the recommendation of the Highways Committee, the Council, undeterred by the obstructive litigation of the companies, should prefer to accomplish the early consolidation of all the lines within its jurisdiction, and to secure the benefits of a comprehensive system of intercommunication as forshadowed in the original proposals of the syndicate, my directors will be prepared, if called upon, to discuss a tenure of 21 years on the basis of a purchase clause, which provides for the redemption of one-third of the expenditure to be amortised by the syndicate under the plan it has promulgated."

Ealing.—At the meeting of the District Council, the Finance Committee reported that they had inspected the profit and loss account of the electric lighting department for the year ended March 31 last, and the account was considered very satisfactory. The Chairman said the accounts had to be signed by himself and the clerk before being forwarded to the Board of Trade. He only received a copy that morning, and he had not had sufficient time to look into it yet. After some discussion, the chairman was authorised to sign the accounts if he found them correct and in proper form. The profit and loss account shows that the cost to the rates on the first year's work has only been about £800. The Electric Lighting Committee reported that the orders received represented 7,144 8-c p. lamps, and of these 6 036 had already been connected. Mr. Griffin asked what was the estimated revenue from the private supply for the present year The Surveyor said it was difficult to give exact figures. The average number of private lamps in use in the past year was about 3,000; the average for the present year would certainly not be less than 6,000. He estimated an addition to the revenue of £1,500, with very little addition to the expenditure.

Leeds.—The Corporate Property Committee have decided to recommend the Council to adopt Alderman Harding's scheme for the laying-out of the City-square, in which the electric light will play so prominent a part. Plans have been prepared by Mr. Wm. Bakewell, architect, Leeds. The *Yorkshire Post* hears that numerous engineering firms in various parts of the country have applied to Dr. Hopkinson, the expert in electric traction to the Corporation, and to the city engineer for specifications, apparently with the object of tendering for the principal portion of engineering work to be done in connection with the experiment with electric traction to be made between Roundhay Park and Kirkstall. In response to the urgent representations of numerous engineers, the committee have determined that the engines shall be horizontal. Sundry alterations have also been made with reference to the driving gear and a few details of minor importance. Tenders are to be sent in by 22nd inst. At a meeting held the other day, the Tramways Committee empowered a sub-committee to enquire as to what outlying district of the city extensions of the tramway system would be most acceptable in. The committee seem to think that the first extension to be taken in hand should be from the existing York-road terminus to the East-end Park. The sub-committee intend to visit various parts of the city in which tramway extensions are desired or desirable.

Morecambe.—In moving the confirmation of the Electric Lighting Committee's report, which stated that Mr. Thomas Parker, of Wolverhampton, had been appointed consulting engineer, Mr. Bellamy explained at the meeting of the District Council why Mr. Parker had been employed by the committee. He would like to refer to an item relating to the probable cost of the undertaking, which was £20,500, as quoted by Mr. Parker. To that amount must be added £505 for land and also the amount to be paid to the electric light company, which would bring the total to £25,000. When Mr. Parkinson, of Morecambe, gave the Council an estimate it was £16,000, being £9,000 difference Mr. Parkinson estimated £16,000 for buying the electric light company's plant, erecting works for the supply of private lights and also the lighting of the streets, the promenade from the Battery to East View to be lighted by 40 arc lamps. Mr. Parker's estimate was different altogether, as he embraced the whole of the district, including Bare and Torrisholme, also the new sea-wall which would probably be built in the future, the promenade to Bare White House to be lighted with 100 arc lamps. Two thousand pounds were estimated for meter rents, but he (Mr. Bellamy) would be pleased if that could be realised. Mr. Miller seconded the adoption of the minutes. In reply to Mr. T. Baxter, the Surveyor stated that he had tested the site selected by Mr. Parker and found good clay 12ft. down. He thought with concrete it would make a good foundation. It was resolved that the Electric Light and the Lighting and Water Supply Committees should be amalgamated, should consist of the whole Council, and should be called the Lighting and Water Supply Committee.

Edinburgh.—At a meeting of the Town Council the Electric Lighting Committee submitted the following report by the consulting engineer (Prof. Kennedy) as to the condition of the plant and mains and the working of the electric lighting station for the year 1895-96: "I have much pleasure in making a report to the Corporation of Edinburgh on the first year's working of their electric light station. The station opened on April 11 last year with about 2,000 lamps on circuit. On May 15, therefore—that is, at the end of your financial year—the station will have been running for 57 weeks. The number of lamps actually connected to the mains is now 51,900, besides 247 arc lamps, equivalent to about 4,500 incandescent, making the total number of lamps connected equivalent to 56,400 lamps of 8 c.p. The number of private consumers connected to the mains of the Corporation is 445; in April, 1895, it was 48. I am extremely glad to be able to say that the financial success of the enterprise has corresponded to the great demand for light. The accounts are not, of course, as yet made out to May 15, but the final weekly reports allow us to estimate all the figures very closely. The total income from incandescent lighting, allowing for meter rents and after deducting all rebates, will be about £13,300. The total income from arc lighting will be about £3,500, making in all an income of about £16,800, or possibly a little more. The total station expenses, including all expenses in trimming arc lamps and supplying carbons, and in maintenance of mains, etc., have been about £4,500. Standing charges, as stated by the town clerk including interest and sinking fund, and also including general charges against the department, amount to about £9 450, making altogether £14,000, and therefore leaving a net profit balance of £2,800. Out of this balance allowance has to be made for depreciation, and I have given this matter very careful consideration. I understand that your sinking fund amounts to 3¼ per cent. per annum—that is to say, that you put by, on account of sinking fund, one-thirtieth of your whole capital expenditure every year. Under these circumstances I do not think it is necessary that you should make any special further depreciation allowance on any items of expenditure which will last for 30 years—that is to say, on which you would not naturally put a higher rate of depreciation than 3¼ per cent. I think that you may consider that all buildings, mains, road-work, and lamp-posts come under this head, and that, therefore, on these items you need not allow any further amount of depreciation. On plant, however, of every kind it would be well that you should allow a total of 5 per cent. for depreciation, or, say, 2 per cent. in addition to what is allowed in the sinking fund. I believe this amount would run on £24,064 of your expenditure, and would therefore involve an additional allowance of £480. On batteries, instruments, arc lamps, meters, transformers, rectifiers, and one or two other matters, on which you have in all expended the sum of £7,850, I think it would be advisable to allow a total depreciation of 10 per cent., or, say, 7 per cent. more than you have already allowed. This would require an additional allowance of £550 altogether, so that you would require a total allowance, in addition to the sinking fund, of, say, £1,030 for depreciation, and this will still leave you a clear balance of from £1,700 to £1,800. I do not attempt to put the figures more exactly than this, because the accounts are not yet made up. The total number of units sold during the 57 weeks from the start until May 15 have been about 560,000 to private consumers and 328,000 for street lighting—in all about 888,000. Your actual works cost per unit will at this rate be under 1·25d. per unit, including lamp trimming and carbons; and if this figure is reached it will be the lowest yet obtained in the country, a result of which I think your Corporation, and in particular the staff at the station, may be justly proud. I went over with Mr. Monkhouse some time since his estimate for

Digitized by Google

the expenditure and receipts for the coming financial year 1896 97, which has already been before your committee. The figures in this estimate as finally adjusted appear to me to be reasonable, and I believe that the actual results will, at any rate, not be behind them. In the estimate the receipts for current are put at £28,000 during the year. The reduction of price from 6d to 5d. in the case of private consumers, and from £20 to £18 in the case of arc lamps, will make a total difference of about £4,100 on the estimate, but this will still leave an ample margin over the expenditure, even without allowing for what I hope may be the fact, that the reduction of price will considerably accelerate the rate at which lamps will be put on to your system." The Town Council has agreed to supply the infirmary with electric light.

PROVISIONAL PATENTS, 1896.

JUNE 8.

12481. Improvements in bracket and chandelier arms for gas, oil, or electric light. Samuel Eaton, Thomas Eaton and Samuel Eaton, jun., 72, Barr-street, St. Georges, Birmingham.

12504. Improvements in or in connection with the transmission and or transformation of electric currents specially applicable for lighting purposes. Bernard Page Scattergood, 30, Park-row, Leeds.

12531. Improvements in switches for making and breaking electric currents. Alfred Slatter and William Rixon, 7, Ridgmount-street, Bedford-square, London

12549. Improvements in and in the manufacture of elements for secondary batteries. Desmond Gerald Fitzgerald, 53, Chancery lane, London.

12550. Improvements in electrical circuit-closing thermometers Alexander Luraschi, 53, Chancery-lane, London.

JUNE 9.

12581. Improvements in the method of supplying electricity to electrically-propelled tramcars and other vehicles, and in apparatus therefor. Percival John Pringle and Julian Money Vernon Money-Kent Morningside, High View-road, Sidcup, Kent.

12587. Improvements in telescopic support for telephone transmitters. Robert Baker, John Filmer, Edgar Lee Ryder, and Alfred Gartner, 18, Fulham-place, Paddington, London.

12588. Improvements in telephone receivers. Robert Baker, John Filmer, Edgar Lee Ryder, and Alfred Gartner, 18, Fulham-place, Paddington, London.

12635. Improvements in electrical switches. George Senior jun., and Thomas Duncan Dundas 44, Blythe-road, London.

12637. Improvements in electric machines and in the method of operating the same. William Henry Cooley, 55, Chancery lane London.

12650. Improvements in thermo electric generators. Harry Barringer Cox and the Cox Thermo-Electric Company, Limited, 46, Lincoln's-inn-fields, London. (Complete specification.)

12676. An improved dynamometer. Jean Benoît Granjon 18, Buckingham-street, Strand, London

12696. Improvements in electrical accumulators. Xavier Marie Roux, 24, Southampton-buildings, Chancery-lane, London.

JUNE 10.

12738. System for the indoor distribution of the electric light. Victor Planques, 8, Rue des Princes, Brussels.

12746. Improvements in two-pin plug for portable electric lamps. William John Head, 60, Chesnut-road, Tottenham, London.

12755. An improvement in the manufacture and insulation of electrical conductors. The Telegraph Manufacturing Company, Limited, Helsby, near Warrington.

JUNE 11.

12859. Improvements in electric transformers. Leslie Bradley Miller, 2, Gray's-inn-road, London

12895. Electric elevators. Humphrey Russell Smith, 260, Dearborn-street, Chicago. (Complete specification.)

JUNE 12.

12959. Improvements in arc lamps specially applicable for lantern purposes. Frederick Woodward Branson, 30, Park-row, Leeds.

12963. An improved grid or plate for secondary batteries. Richard Norman Lucas, The Voltage, Woking, Surrey.

13023. Improvements in casings for electric conductors. Henry Reason, Norfolk House, Norfolk-street, London.

JUNE 13.

13046. Improvements in and connected with cleats for electric and other wires and the like. Frederic Brigham Evans, 23, Coleman-street, London. (Complete specification.)

13048. An electric lamp and oil-can combined. James Rhodes and James Henderson, Bridge End, Wakefield.

13074. Improvements in the manufacture of electrical resistances. Augustus John Marquand and David Lowden, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13079. Improvements in or connected with dry batteries and the like. William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Christian Lesenberg, Germany.) (Complete specification.)

13080. Improvements in or applicable to electric meters. Albert Lotz, 6, Bank-street, Manchester. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1889

19420. Electromagnetic motors. Lake. (Tesla.) (Second edition.

1894.

10632. Electrolysis. Gautier. (Second edition.)

NOTES.

Dundee Institute.—The annual general meeting of the Dundee Institute of Architecture, Science, and Art, will be held on Tuesday, 30th inst.

The Marine Engineers.—The annual dinner of the Institute of Marine Engineers was held last week at the Holborn Restaurant, Sir Edwyn Sandys Dawes, the president, being in the chair.

Accident.—It is with very great regret that we learn that Mr. Lennox, of the laboratory at the Royal Institution, has received terrible injuries from an explosion of apparatus containing acetylene under high pressure.

Books Received.—We have to acknowledge the receipt of "Electricity in the Dwelling," an address delivered to the Royal Scottish Society of Arts by the Right Hon. J. H. A. Macdonald, F.R.S. It is published by Messrs. Blackwood and Sons.

Lord Kelvin.—It is announced that Lord Kelvin will preside at the unveiling of Mr. W. D. Stevenson's bronze statue of "Highland Mary" at Dunoon, Argyllshire, on August 1. The statue is intended to commemorate the centenary of the death of Robert Burns.

A French Tangiers Cable.—It has been reported from Tangiers that the French Government intends to lay a telegraph cable between Tangiers and the coast of France or a French possession. Of course, it is quite impossible to tell what projects may have been discussed or decided on in French Government telegraphic circles, but the report, to say the least, requires confirmation.

Utilising Water Power.—The *Bradford Observer* hopes, "if only for the scientific novelty as regards this part of the country, where water power is scarce," that the Bingley District Council will be able to come to terms with the canal company in regard to the offer of the company to supply the town with electricity from dynamos driven by the power which at present goes to waste at the canal locks.

Catalogue of Scientific Literature.—The approaching international conference arranged by the Royal Society to consider proposals for an international catalogue of scientific literature will be opened at Burlington House on July 14. The total number of delegates appointed to attend the conference amounts to 40, including representatives of the principal colonies of the Empire and the principal Governments of the world.

Chicago Exhibition.—The medals and diplomas awarded to British exhibitors at the late Chicago Exhibition have at length been issued to H.B.M. Ambassador at Washington, and have been transmitted by him to the Foreign Office. Sir Henry Trueman Wood has been requested by the Secretary of State to undertake the duty of distributing them, and this will be done at once. All the exhibitors may expect to receive their medals within about a month from the present date.

Obituary.—Mr. John Lionel Blakiston, one of the two telegraphists killed on the rescue party from Fort Salisbury to Mazoe on Saturday last, was the third son of the Rev. Douglas Y. Blakiston, vicar of East Grinstead, Sussex. He had been in South Africa in the service of the Government Railway Department, when he was offered a post on the trans-continental telegraph construction, for which he was qualifying by work between Victoria and Charter, and since March at Salisbury.

Society of Arts.—The council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a gold medal, or a prize of £20, for any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means. Intending competitors should send in descriptions of their inventions not later than December 31, 1896, to the secretary of the Society of Arts, Adelphi, London, W.C.

Carriage Makers and Motorcarts.—In the course of his address to the Institute of Carriage Manufacturers on Tuesday, Mr. G. J. Jacobs (the president) referred to the subject of motorcarts. He was inclined to regard the advent of the "autocar" without alarm, and if the result of it should be that the carriages of the future were increasingly light, easy, and elegant carriage makers had nothing to fear from, but for many reasons they would welcome, the new comer. At the dinner in the evening Sir Henry Trueman Wood, in proposing the principal toast, spoke to somewhat similar effect.

Acetylene Motor.—According to the *Rivista Tecnica*, Mr. G. Pedreti, of Parma, has invented an acetylene motor which he believes will be suitable for small motor carriages and tricycles. He uses a mixture of one-sixteenth of acetylene to fifteen-sixteenths air, and it is stated that a water-jacket on the cylinder is not necessary, as the cooling is done by the admission of the mixed gas and air, from which it may be fairly inferred that it is proposed to generate the acetylene under pressure. As the details of the machine, including the method of ignition, are at present kept secret, it would be premature to criticise the extremely favourable results which are said to have been attained.

Electrical Congress at Geneva.—Invitations are now being sent out for the International Electrical Congress organised by the Swiss Society of Electrical Engineers, and to be held from August 4 to 9 next. Information relative to the congress will be given at the office of the International Electrical Congress at the Université, Geneva, and all who may desire to take part in the congress should apply there. The programme of subjects for discussion has already been given in these columns, and papers to be contributed should be sent in in MS. before July 20. It is worth note that the sittings of the congress are fixed for 8 a.m. Mr. Raoul Pictet has promised a demonstration on the subject of low temperature and on "Cathode Rays." The price of a ticket for the congress is 20fr. and 15fr. for a lady.

Rontgen Radiations.—Mr. T. C. Porter, of Eton, has written to *Nature* a long letter describing some curious results of his experiments. In comparing the results obtained by different observers it seems that it is important that the exact temperature should be given, though it does not appear how far Mr. Porter eliminated the direct effect (if any) of temperature on the discharge with its indirect action in affecting the vacuum. A second curious result comes to this—namely, that any arrangement by which a charge on the outside of the tube behind the cathode would be subject to intermittent removal (for instance, a ring of copper wire earthed, and nearly, but not quite, touching the glass of the tube) greatly increases the fluorescence and photographic action of the discharge, as well as prevents "fatigue" of the tube.

Incandescent Gas Patents.—After a three days' hearing, the Master of the Rolls and Lords Justices Kay and Smith have dismissed an appeal by De Mare Incandescent Gas Light System, Limited, and (on a minor point) the Sunlight Incandescent Gas Lamp Company, Limited, from the judgment of Mr. Justice Wills, in April, at the suit of the Incandescent Gas Light Company, Limited, holding the defendants to have infringed

Digitized by Google

the plaintiffs' Welsbach patent in gaslight mantles. Their lordships, however, were unanimous in agreeing with Mr. Justice Wills and his ruling, on the authority of Lord Cairns, that it was sufficient to establish infringement to show that the substance and essence of a patent had been taken and adopted, as Mr. Justice Wills said had been the case in the present instance.

Institution of Electrical Engineers.—We have received the June issue of the *Journal* of the Institution of Electrical Engineers, containing Mr. Dane Sinclair's paper on "Telephone Exchangcs" and Mr. Langdon's on "Railway Telegraphs," with the discussions. It will be remembered that, in view of the close of the session, the discussions had to be kept within very strict limits of time. Hence there are several interesting communicated additions to these. Among them we notice that Mr. Hollins, of the Great Eastern Railway, incidentally promises a paper on electric interlocking of railway signals for next session. As to the abstracts, there are 16 of them, of which six relate to the subject of the Röntgen rays. By permission of Major Cardew, arrangements have been made for a visit of students of the institution to the Board of Trade standardising laboratory, 8, Richmond-terrace, Whitehall, on Saturday, July 4, at 11 a.m. The party is limited to 20, and students desirous of being included in it should signify their intention to Mr. G. C. Allingham, Eldon House, Lyndhurst-road, Hampstead, N.W., in the usual manner.

Alternating-Current Motors.—The Langdon Davies alternating-current motor is a self-starting one. Two circuits are used, and the motor differs from others designed on similar principles in the careful way in which the proper arrangement and proportion of the coils has been worked out. The motor has received the honour of a description in the *Times*, which begins with the ingenuous remark that "the alternating-current system of distributing electrical power is generally admitted to have distinct advantages in comparison with the direct-current system." All the direct-current people—who, it is understood, have usually something to say for themselves—having been thus summarily ruled out, it is added that the polyphase system "is not very common." Certainly it is not—at present—in Great Britain. Moreover, though, of course, everyone would like to see a good alternating-current motor, the question of motors is hardly one which would determine the preference of a continuous-current system. In fact, up to the present motors have taken a very minor place in the calculations of the electrical engineer.

Resistivity of Alloys.—That troublesome conception, the "back E.M.F. which is proportional to the current, and therefore in measurements is not separated from a resistance," has appeared in a new place. It has been heard of in connection with the arc, and now Lord Rayleigh wants to find a place for it in the abnormal resistivity of alloys in Prof. Dewar and Prof. Fleming's low-temperature experiments. At any rate, in a letter to *Nature*, he points out that in a material made up of a large number of small laminæ, when the current flows across them heat would be produced at one set of the junctions and increase until balanced by conduction through the metal to the other junctions. Considered thermo-electrically, the result works out as a back E.M.F. proportional to the current, but (probably) independent of the number of laminæ. Lord Rayleigh considers that something analogous to this action should have some bearing on part at least of the resistivity of alloys. It should be said, however, that in the example he works out the percentage of the false resistance is a very small one. Moreover, distinctions which are clear cut enough in dealing with masses of matter of appreciable size may easily change their character when we get into the region of the molecules and atoms whose structure and motion determine the properties with which we are dealing. It therefore seems at least questionable how far the extension of the theory indicated above into such regions is legitimate.

London Tramways.—The London County Council have discussed the report of the Highways Committee with reference to the proposals of the County of London Tramways Syndicate with reference to leasing the lines and introducing electric traction. The recommendation of the committee was that the syndicate should be informed that the Council were not prepared to enter into any arrangements with them. The Council agreed to this at once without discussion. There was another proposal to purchase the tramways of the North Metropolitan and London Street Tramways Companies at a total price of £675,000, and to lease the lines back to the companies at a rental of £45,000 with a percentage on the increase of the receipts. This the committee recommended for adoption, and the first of their reasons for doing so is instructive—namely, "that a lease for 14 years is preferable to one for 28 years." In others words, that course is preferred which adds to the power of the Council. There was a discussion of the type with which Spring-gardens has made us familiar, and ultimately the matter was referred back to the committee. The views of those people who object to tramways altogether as cutting up the streets are intelligible. They are old-fashioned, that is all, but in their way logical. But when you have got tramways, it seems absurd not to have the best ones possible. As Lord Mountmorres remarked in the course of the debate, the horse-traction system is getting entirely out of date, and it would be a lamentable pity if any course was adopted which would prevent London from being provided with a tramway service as efficient as can be found amongst the other great cities of the world.

Lighthouses.—Mr. J. R. Wigham has written to the *Times* to suggest that the loss of the "Drummond Castle" was due to the Ushant lighthouse being an electrically lighted one. It is, in fact, one of the most powerful electric lights on the coasts of France, or, for the matter of that, in the world. As it is asked that the Board of Trade and the Trinity House should reconsider their position and come to a decision not to permit any more electric lights for lighthouse purposes to be erected, it may be worth while to remark that whatever views may be put forward as to the "fog-piercing" power of the electric light, the loss of the "Drummond" has nothing to do with the point. Where precisely that unfortunate ship met her doom is not known, for the wreck cannot be found, and the three survivors could have no means of telling; but all the evidence goes to show that it was not near the Ushant light, but on the other side of the island altogether, and in the channel between it and the mainland. The Currie Company, in confessing that they have been unable to find where the "Drummond Castle" was wrecked, add that they have been distinctly informed that the siren on Ushant was not sounding at the time, from which it may be inferred that on the lighthouse side there was no fog or haze, though, of course, there might very well be in the channel. The really curious thing is that if the "Drummond Castle" took the wrong course she is supposed to have done, she ought to have passed on her starboard side one, if not two, lights, which—writing without references—it is believed are not electric. Any or all of these would, of course, be distinguishable from each other by their flash. The Ushant light is not a mere warning to keep off, but as soon as it is picked up in crossing the Bay it is known

Digitized by Google

exactly where the ship is and the proper course. For long-distance work of this character there is admittedly nothing like the arc. And with every deference to the advocates of the Wigham gas lighthouse, no light at all is much good in a fog.

Absolute Measurement of Resistance.—The following description is from the *Times*: Under the direction of Prof. Viriamu Jones, of University College, Cardiff, who has been working at the subject for some years, Messrs. Nalder and Co., of Clerkenwell, have just constructed a machine on the Lorenz method for the M'Gill University which will give a unit of electrical resistance conditioned only by the units of length and time and the properties of the ether. The principle upon which this machine depends is that in a metal disc rotating in the field of force produced by a coil of wire in which electricity is flowing, a current is set up between centre and circumference which varies strictly as the rate of rotation. The resistance to be measured is put in circuit with the coil and a current sent along it, while at the same time the induced current from the disc is sent through the resistance, but in the opposite direction. By varying the rate of the disc a speed is found at which the two opposing currents neutralise each other, and the product of this speed into the coefficient of mutual induction between the coil and disc is the resistance in absolute units. This coefficient can be exactly calculated if the dimensions of the coil and disc are exactly known. In the present machine the utmost precautions have been taken to make every portion perfectly true. The coil, which consists of 200 turns of specially-drawn bare copper wire wound in a screw-thread cut with microscopical accuracy, is carried on a marble cylinder 21in. in diameter, which deviates from the circular by less than two parts in 100,000. The current is taken off the disc, which is very carefully centred, by four brushes through which a constant stream of mercury passes in order to ensure perfect electrical continuity. The bearings are fitted very exactly, and are lubricated by a small pump supplying oil at considerable pressure. Elaborate devices are also provided for adjusting and measuring the speed. The machine is expected to give results accurate to at least one part in 10,000.

The Edison Fluorescent Lamp.—Mr. Edison's new lamp is the subject of a short description in the New York *Electrical Engineer*. It appears that the fluorescent substance as to which Mr. Edison would only say at first that it was easily obtainable, is tungstate of calcium after all. This is fused on the interior of a Crookes vacuum tube, and fluoresces when the discharge passes. "Mr. Edison has found that such a tube shows an entire absence of X-rays externally, and, what is more, no rise in temperature can be detected with a clinical thermometer." The latter seems a curious instrument to use to measure the temperature of a glass tube, or even the radiation from it, but upon this evidence it appears to be concluded that the "entire energy of the X-rays is absorbed by the fluorescent material which emits light." Mr. Edison has also noted that when employed as fluorescent bodies within the tube, instead of outside, as usually employed, some substances develop a higher degree of fluorescence even than tungstate of calcium. It is a very old discovery of Mr. Crookes's that the behaviour of fluorescing substances in a vacuum tube is altogether different to what can take place outside. For the rest it will be better to reproduce the actual words of our contemporary: "As regards the efficiency of the new lamp, Mr. Edison has made preliminary measurements which seem to indicate a very high economy. Thus, measurements were taken on a lamp which Mr. Edison estimated to be of about 1 c.p. The measurement was made by placing a Kennelly direct-current ammeter and a Weston direct-current voltmeter in the circuit feeding the primary of the induction coil connected to the lamp. The ammeter showed an average of two amperes, and the voltmeter 0·3 volt, which would indicate a consumption of 0·6 watt for the lamp of estimated 1 c.p. This result is so remarkable that Mr. Edison himself has doubts as to the accuracy of the indications of the instruments, in view of the peculiar nature of the interrupted current obtained in connection with the induction coil. The current in Mr. Edison's experiments is interrupted over 14,000 times per minute. Mr. Edison proposes during the present week to carry out a complete series of accurate photometric and electrical tests with instruments and in a manner which will not be open to question as to their reliability." A process-block illustration is given of the new fluorescent lamp "as it appears in Mr. Edison's laboratory." The photograph was taken by the light of the lamp itself, with an exposure of about 30 seconds. In the engraving where the lamp should be there is a mere nebulous glow, and the rest of the block is an unflattering portrait of Mr. Edison. The photograph and exposure, however, show that the light of the new lamp must contain a very large proportion of what used to be called actinic rays.

Fluorescence Visible and Invisible.—There has been some discussion in the Société Française de Physique on the subject of the nature of fluorescence, and particularly that produced by the Röntgen radiations. The subject is one which has at present only a purely scientific interest, and it is therefore left to those who are willing and able to spend time on the researches necessary to complete the theory of light and enable a rational account to be given of the new phenomena. But in view of the possibility of a fluorescent lamp being the ultimate result of the vacuum tube experiments now being made in the United States and elsewhere, the whole subject may any day become one of great practical importance. It has been known for some time that uranium salts and metallic uranium itself under the action of ordinary light emit radiations which are invisible to the eye, but can be reflected and refracted to a certain extent, while so far as concerns their action on a photographic plate and their power of passing through substances which are opaque to ordinary light, they resemble the Röntgen radiations. Most of the work in this direction has been done by Mr. Becquerel, but other investigators have obtained somewhat similar results with other substances, though the effect is not nearly so enduring as with uranium salts. Now, in general, in the process of fluorescence the radiations given off are of greater length than those received by the fluorescing substance, and Stokes's law, as it is called, is the expression of the theoretical reason why on the whole it should be so. But if the hypothesis is correct that the Röntgen rays and the uranium radiations belong to the region beyond the ultra-violet, we have apparently a direct contradiction of this, and what looks like a case in which the wave-length is shortened, which, of course, is just what is wanted to be done in order to utilise the energy wasted in producing invisible "heat" waves in almost every known form of artificial illumination. But at the Société it was pointed out by Mr. Guillaume that if a sufficiently complicated structure was assumed it was not theoretically necessary that there should be a degradation of all the wave-lengths, provided that the average length was lowered. It was therefore not impossible that a part of the emitted rays might have a shorter wave-length than the primitive radiation, provided that there was at the same time a sufficient amount of radiations of greatly increased wave-length. The subject

Digitized by Google

is one of great difficulty both from a theoretical and an experimental point of view. Indeed, owing to the non homogeneous character of the radiations, and the impossibility of sifting them out, so to say, no two observers seem to get exactly the same results. But it seems at least probable that the theoretical difficulties which have been believed to block the way to an efficient fluorescence lamp do not really exist. Whether anything practical will be effected in this direction time will show.

Royal Institution.—There was a large audience to hear what Mr. T. C. Martin had to say about Niagara at the extra evening discourse which was arranged for last Friday. Lord Kelvin, who had come straight back from the jubilee celebrations at Glasgow, took the chair, and his entrance into the lecture theatre was the occasion of something like a demonstration from the audience in his honour. Among others present were Lord Rayleigh, Prof. Ayrton, Sir Frederick Bramwell, Sir Douglas Galton, M. Moissan, Sir W. Farrer, Sir W. Priestley, Sir F. Abel, Sir B. Baker, Lord Windsor, Earl Percy, and Sir J. Lister, Prof. Dewar, Mr. Alexander Siemens, Mr. Webb, Prof. Silvanus Thompson, etc. After a discourse there is usually something worth looking at in the library of the institution. On this occasion there was a telautograph transmitting written messages. Instead of sending the message as far off as possible, the distance was only to the next table, so that visitors could compare the written and received messages as they were produced. The instrument was, it is believed, shown in the same place some time last year. It did its work very nicely. What appears to stand in the way of its coming into extensive use is that at present four wires are required, which makes the line come expensive. In one of the windows the white flame of acetylene made itself sufficiently prominent; in another window recess was the Ayrton and Mather magnetic tester referred to in these columns last week. Next to this was an apparatus for indicating the magnetic field. An exploring coil is mounted in a handle containing a spring, which on touching a trigger rotates the coil rapidly through an angle of 180deg. The result is read on a ballistic galvanometer. The peculiar fascination of this instrument was that anybody coming along could set the coil, touch it off, see the needle swing, and think he had done something without troubling himself to consider exactly what was required to get accurate results. It was of course explained to anyone who appreciated these matters. In a corner protected from the light by curtains were Messrs. Siemens Bros.' facsimiles of early vacuum work instruments. As long ago as 1785 Morgan, by long continued boiling of the mercury in the barometer tube, produced a Torricellian vacuum of such excellence that no electric discharge that could be produced by the frictional machines, which were the only instruments available in those days, could be got to pass. Beside this was a series of four tubes designed by Dr. Eugene Obach showing the character of the electric discharge at different degrees of exhaustion. The pressures in the tubes were 70mm., 6mm., 2mm., and 0mm. (or as near as can be got to it) respectively. It was very curious to note the complete change in the character of the discharge between the pressures of 6mm. and 2mm., and also the variation in the striations in the high-vacuum tubes under the influence of a magnet.

Mr. Martin on Niagara.—An extra Friday evening discourse was given at the Royal Institution last week by Mr. Thomas C. Martin, who has come over from New York as American delegate to the Kelvin jubilee celebration. The subject of Mr. Martin's discourse was the utilisation of Niagara and the work that had been done by the Niagara Falls Power Company. This was illustrated with a very large number of lantern slides, some of which were very beautiful. As much of the discourse took the form of comment on these, a detailed report of it would hardly do justice to the lecturer, and as regards the actual facts given would necessarily contain much that would be practically a repetition of what has already appeared at one time or another in these columns. Mr. Martin is, of course, well known in connection with one of the first electrical journals in the United States, but as a speaker he is entirely new — at any rate at the Royal Institution. At times his way of putting things very much took the fancy of his audience. Opening with the remark that it was curious that almost alone among the physical features of the Western world the greatest of them should have formed the scene of no notable work of poetry or fiction, and have even failed to receive adequate treatment from the artist's brush, Mr. Martin said that Niagara had remained unpictured, unhistoried, and unsung—with one exception, the excursion literature of the New York Central Railroad. After referring to the 164ft. fall which could be utilised, and the various estimates of the amount of water passing over, Mr. Martin said this varied very much indeed, and consequently the height of the river above and below the falls alters very considerably. Last spring, owing to ice and strong winds, he had seen the falls almost dry. If this is the case, it is obvious that the varying estimates, afterwards alluded to, which have been made as to the total energy of the falls are easily accounted for. After a reference to some of the extraordinary schemes proposed for utilising the power of the falls, Mr. Martin said that Mr. Evershed had suggested that, unlike most water powers, they should have a short canal and a long tail-race, and with the modification involved in the use of electricity this had been adopted. The effect was that there was absolutely no injury to the natural beauties of the neighbourhood. The intake was far above the falls, and the outflow from the tail-race tunnel was underneath a suspension bridge. Nothing, in fact, was visible from the falls. On the other hand, the ordinary practice of a long canal and a short tail-race brought all the mills in a cluster to the edge of the river, and some of the American mills were not pretty objects. Of course, these sort of things sound much better in a lecture-hall than they read in print when separated from their context; but some of Mr. Martin's remarks insist on sticking in the memory. His description, for instance, of the ordinary switchboard as something like an exaggerated street-door with an absurdly unnecessary number of knobs, knockers, and handles appeals to every visitor to a generating station. As to the electric railway in the gorge below the falls, which in places is bracketed out from the cliff over the water, he refused to state how the passengers were saved when the cars ran off the rail, but could strongly recommend a ride on it as giving altogether the biggest shillingsworth of thrill to be obtained anywhere. That was on the American side; the Canadians ran their railway along the top of the cliff in a more Canadian or, perhaps, a more English manner. After engaging the attention of the audience in a calculation showing that the current produced at Niagara could be carried 350 miles to Albany to compete there successfully with coal at 12s. 6d. per ton, Mr. Martin mildly remarked, "But I consider these figures extremely hypothetical." The gem of the evening, however, was unintentional. Mr. Martin inadvertently substituted miles for feet in giving the height of a mountain, but as soon as the applause of his audience showed him what had happened, immediately explained it as the effect of the American habit of exaggeration getting the mastery of him.

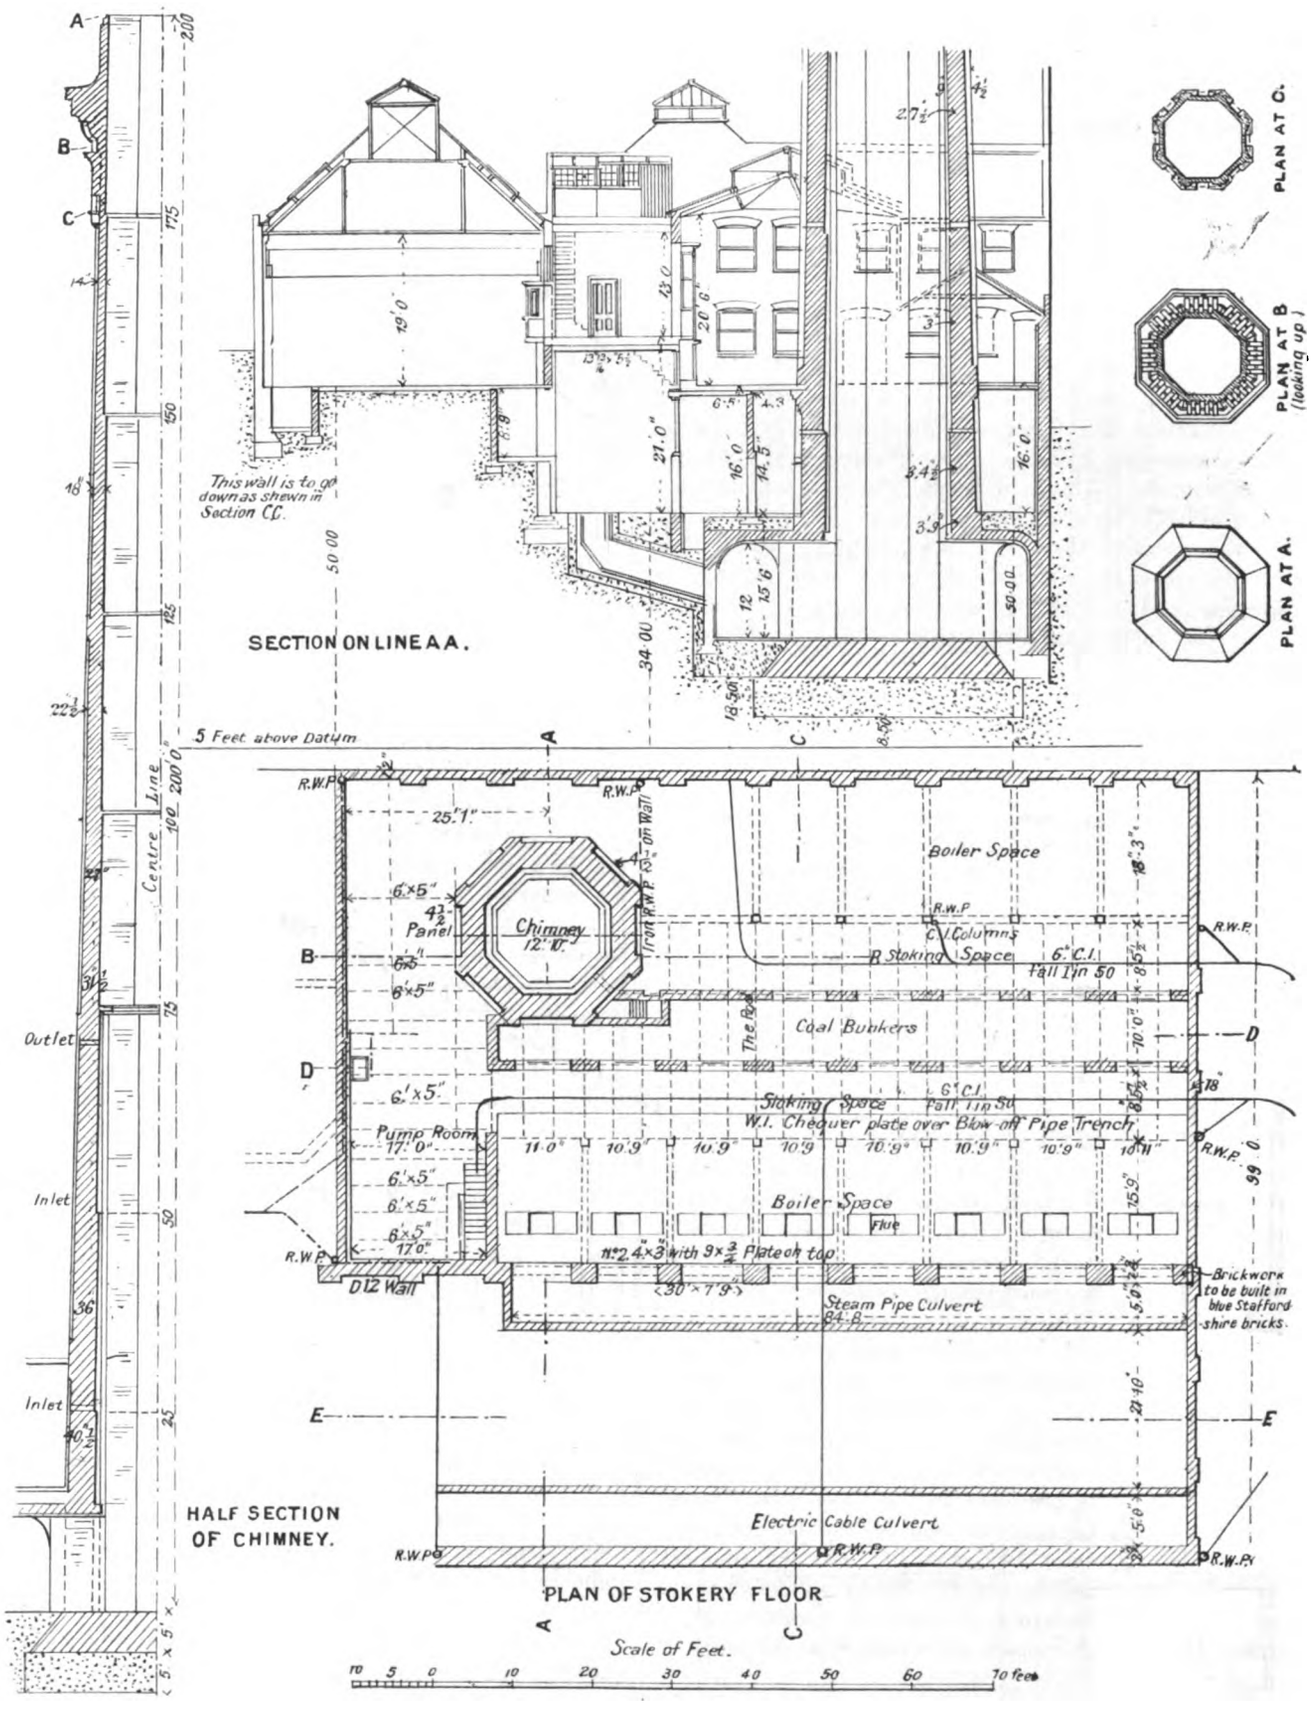
BRIGHTON CENTRAL STATION EXTENSION.

Herewith we illustrate the buildings of the Brighton station, which have been designed by Mr. F. J. C. May, M.I.C.E., the borough engineer. The illustrations explain themselves, and it will be almost needless to point out that all the arrangements have been made for easy and economical working that the long experience gained at this station has shown necessary.



Details of Extensions at Brighton Electricity Works.

HARTLEPOOL ELECTRIC TRAMWAYS.

The following details in connection with the Hartlepool electric tramways have been given us by the Electric Construction Company, Limited, who carried out the equipment of the line on behalf of the General Electric Tramways Company, Limited. The inspection for the Board of Trade was made by Major Cardew and Colonel Yorke on May 14, and the line was opened for public service on May 19.

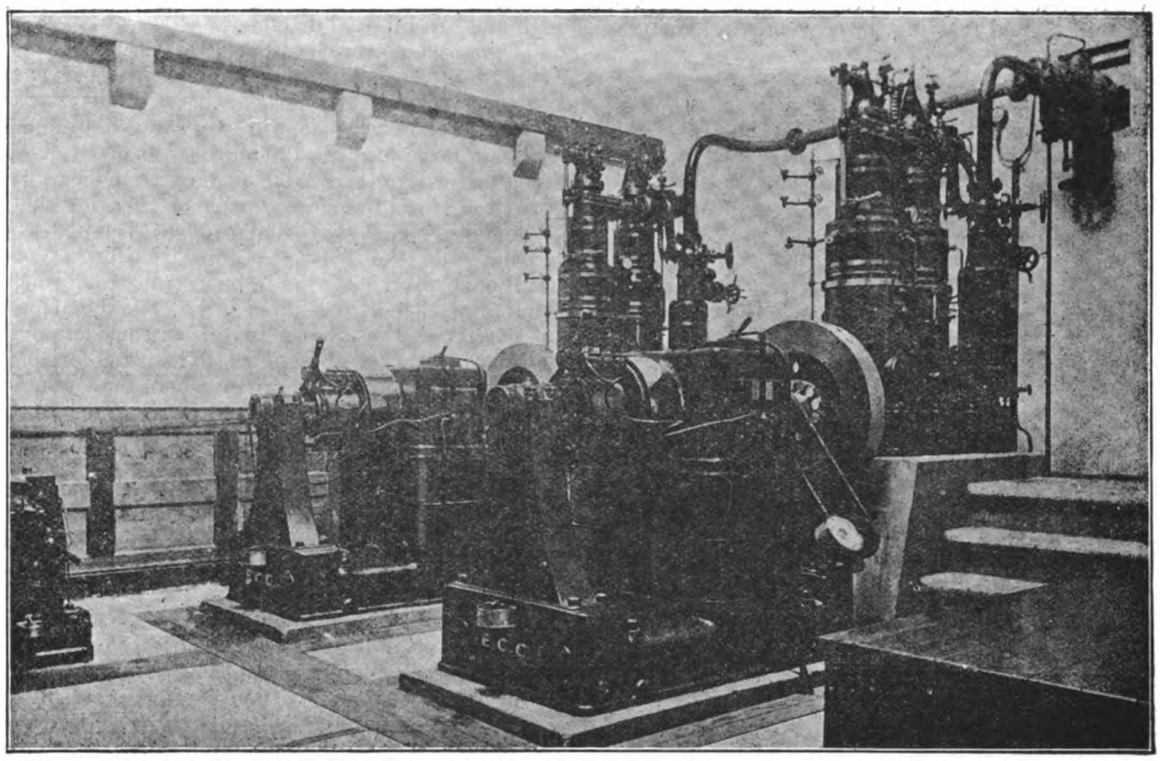
The original tramline dates from 1884, and was worked by steam until 1891, when, falling into a derelict condition, from Northgate-street, in the old town of Hartlepool, to Church-street, in the new town of West Hartlepool, both



Direct-Coupled Engines and Dynamos at Hartlepool.

it was closed. The rights were acquired early in 1895 by the General Electric Tramways Company for the purpose ends extending a little beyond the North-Eastern Railway Company's stations. At present, however, the cars do not

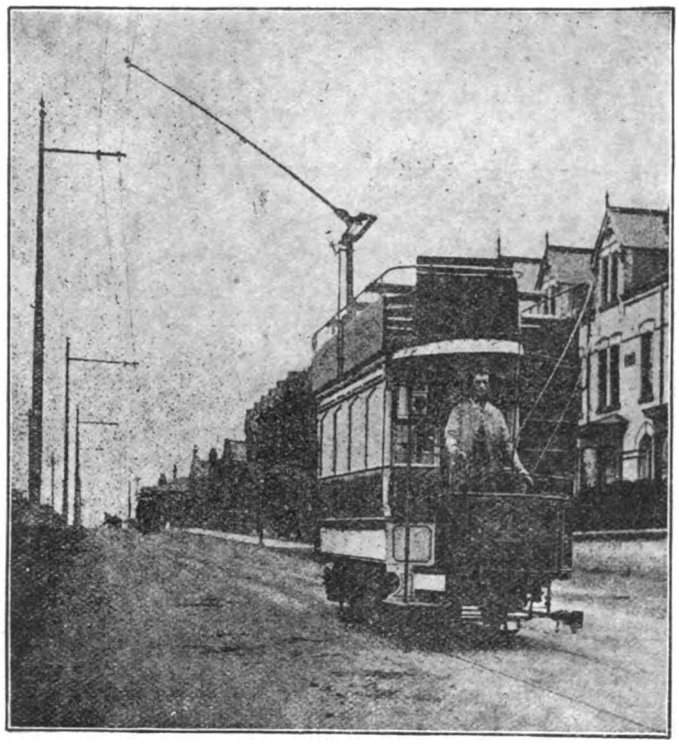
of equipment on the overhead system. The total length of the line is 2½ miles. It joins the two Hartlepools, stretching run at the West Hartlepool end beyond the Municipal Buildings (about 500 yards short of the full length), per-

Digitized by Google

mission not having yet been obtained for the erection of posts on the remaining portion of the line. The entire roadway has been repaired by lifting the rails, rebedding them on concrete, and relaying the pavement. There is a single track with 16 turn-outs. It follows the centre of the roadway, and is laid with 65lb. girder rails. The gauge is 3ft. 6in., and the maximum gradient is 1 in 40, the minimum radius of curve being 40ft. The generating station is almost equidistant from the ends.

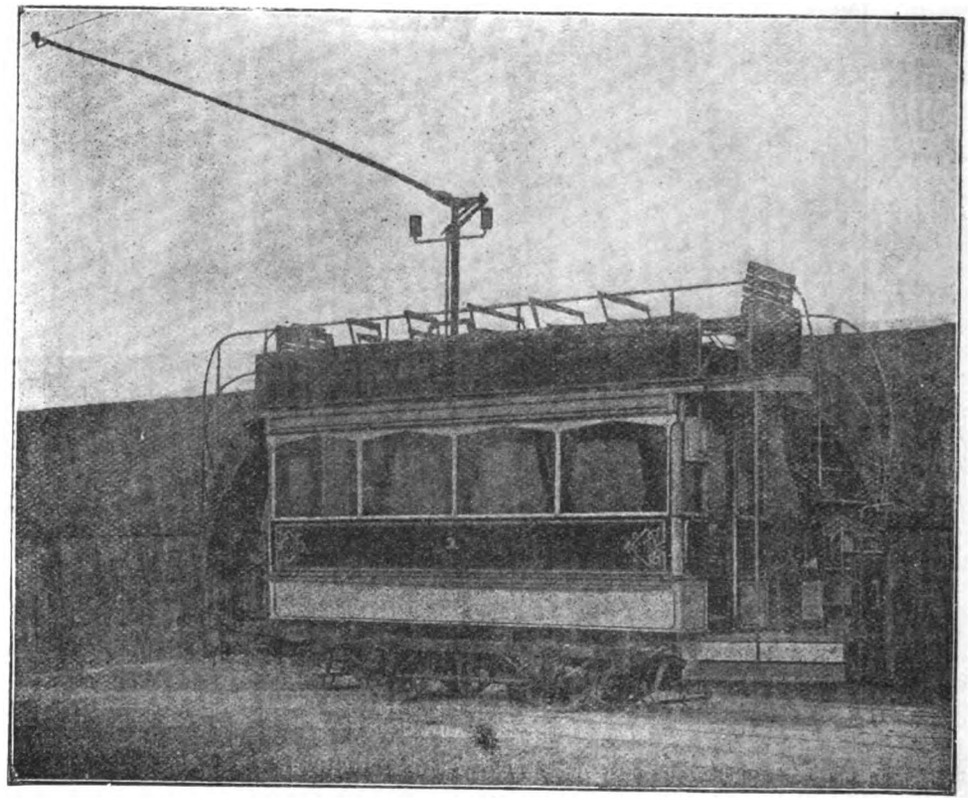


View of Car on Hartlepool Tramways, showing Connection with Trolley Wires.

Generating Plant.—The boilers are in duplicate, of the Galloway type, and were manufactured by Messrs. Galloway, of Manchester. They are 20ft. long and 6ft. in diameter, are capable of evaporating 3,400lb. of water per hour, and work at 140lb. pressure. They are fed by an electrically-driven three-throw feed-pump, 6in. stroke, 2in. diameter, which, at 65 revolutions per minute, is capable of delivering 700 gallons of water per hour. The chimney is 100ft. high and 6ft. internal diameter.

The motive power consists of two G.G.S. Willans engines of 100 i.h.p., running at 450 revolutions per minute and provided with an automatic cut-off. The dynamos—of which there are two—are directly coupled to the engines. Their normal output is 120 amperes at 500 volts, but they are designed to carry 50 per cent. momentary excess current, and are therefore capable of checking the speed of the engine. They have independent bed-plates and two bearings and the shafts are coupled by bolts bushed with hard indiarubber enclosed in brass tubes to deaden concussions transmitted from the engine. The dynamos being of the over type, the engines have been considerably elevated in order to bring the bearings into line, and for this purpose the floor at the end of the room where the engines stand is raised 3ft. 3in. above the ground level. The armatures are wound on the Eickemeyer system, and the magnets are compounded. Copper brushes are used, and the commutators run sparkless at all loads. The commercial efficiency of the dynamos is 93 per cent., and the efficiency of the combined set about 84 per cent. One engine and dynamo suffice for the service of four cars, the second set being in reserve. Provision is made for third set should a heavier service be demanded.

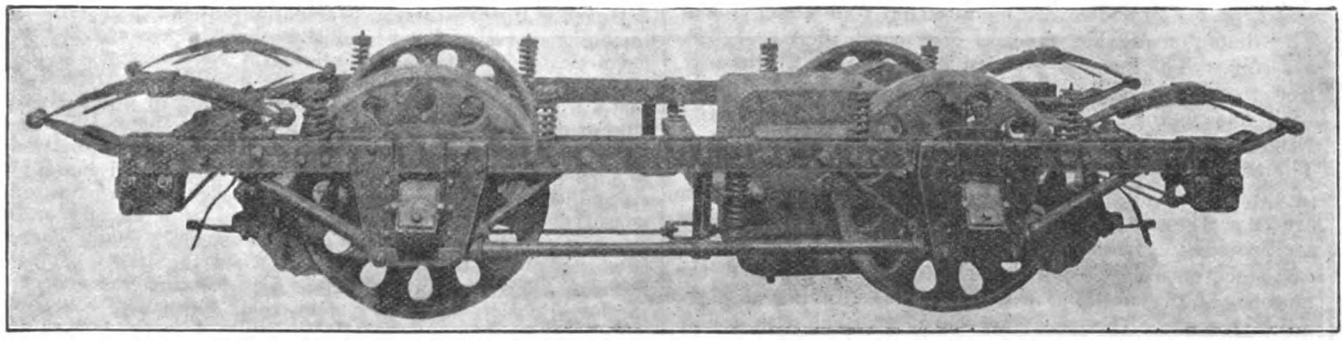
An interesting feature in the general arrangement is the provision of an auxiliary plant, consisting of a secondary battery and dynamotor driven from the generating dynamos. The cells are charged simultaneously with the working of the line whilst the load is light, but at moments of excessive demand the direction of the current is reversed, so that they supplement the current supplied to the cars by the generating dynamos, thus rendering the load less variable, and increasing the working capacity of the system. The arrangement also serves at 100 volts for driving the feed-pump, lighting the station, and moving the cars in the car barn; and as the current from the accumulators is available at all hours, it is possible to run late or early cars when the engines are not at work. The dynamotor is of the improved type now being constructed by the Electric Construction Company, with a double-wound armature for 500 volts 30 amperes and 135 volts 85 amperes. The efficiency of conversion is 85 per cent. It runs at 800 revolutions. The secondary battery consists of 53 E.P.S. 31K cells.



Car on the Hartlepool Electric Tramways.

Digitized by Google

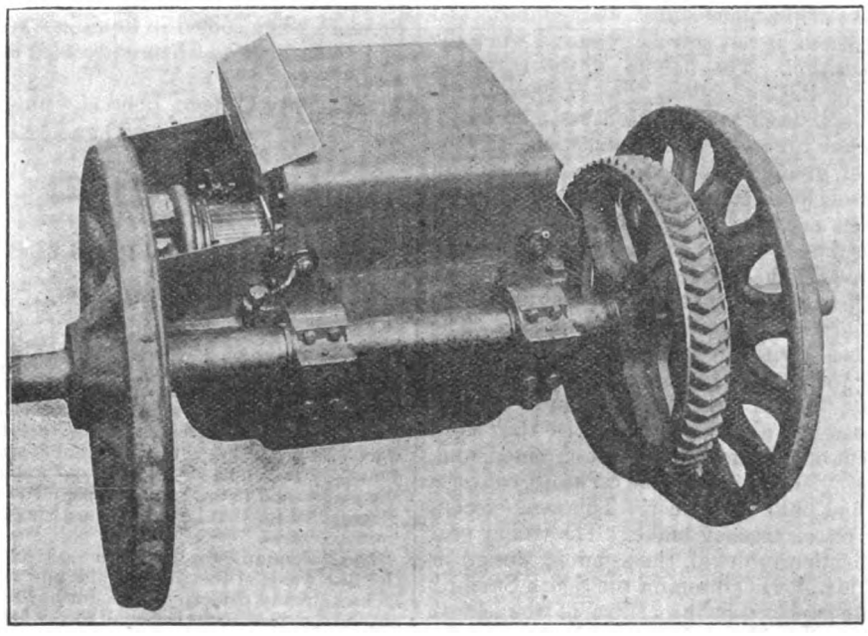
The switchboard stands in the engine-room, and is provided with single-pole automatic cut-out switches for each circuit, and also with single-pole throw-over switches for each dynamo, thus serving to connect them with either of the two circuits into which the line is divided. On the other pole are placed fuses enclosed in glass tubes, with spring connections, enabling them to be instantaneously replaced. Dead-beat Weston ammeters are used on the line circuits and "E.C.C." ammeters on the dynamos. The voltmeters are Kelvin's electrostatic pattern, and suitable switches are provided for the transformers lighting circuits,



Four Wheel Truck on which the Cars are Mounted.

etc., the dynamos being provided with regulating resistances. Across the terminals of the automatic cut-outs are placed resistances to carry 60 amperes. These, when through excess of current the switches open, still permit half the normal current to pass into the line, racing of the engines and dislocation of the traffic due to complete cessation of current from transient causes being thus avoided. The sparking across the switches is, moreover, greatly reduced, and the attendants can with impunity close them to ascertain whether working can be continued or whether permanent short-circuit exists.

Line Equipment.—The general arrangement is the same as on the South Staffordshire Tramways—namely, the side



View of Motor—Hartlepool Electric Tramways.

pole system as originally designed by Mr. A. Dickinson, M.I.C.E., and adopted by the Electric Construction Company. No attempt at ornamentation has been made in the poles, but owing to their position at the side of the road, and the entire absence of span wires, they are wholly free from any unsightliness or from the other grave objections which have been advanced against the introduction of the overhead system in this country. The advantageous position of the station and the moderate length of the line and service render feeders unnecessary, two trolley wires of No. 0 B.W.G. sufficing to carry the current. One of these wires takes the up and the other the down service, and they are cross-connected at two points so as to supplement one another. One circuit takes the line on the side of Hartlepool and the other on the side of West Hartlepool, sectional insulators being placed halfway in either direction, so that in the event of an accident happening to one of the trolley wires, pressure can still be maintained on the other. Two wires also do away with the necessity of any turn-out switches, and simplify the working. The poles are placed on the kerb, 120ft. apart on the straight part of the line but somewhat nearer on the curves. To keep the trolley wire as nearly as possible at a uniform distance from the centre of the track, the length of the arms varies from 4ft. to 12ft. The height of the trolley wire above the line is 21ft., except at two points where bridges on the North-Eastern Railway cross the road, necessitating a reduction to 16ft. It might be thought that the depression of the trolley poles here required would cause trouble in working, but such has not proved to be the case, and there is absolutely no tendency for the trolley wheel to leave the wire at these points. The insulators are of the Ætna type, the wires being clipped in long ears without soldering. The poles were supplied by Messrs. J. Russell and Sons, Limited, of Wednesbury, and are taper steel tubes 29ft. long, 6in. diameter at the ground level, and 2½in. diameter at the arms. At the curves 7in. poles are used, and terminal poles 12in. diameter are provided to take the end strain of the wires. The rails are used as an uninsulated earth return. Electrical continuity between the rail joints is secured by means of duplicate bonds as well as by the fishplates. The bonds consist of No. 4 B.W.G. copper wire wrapped round and soldered to the end of a taper iron stud which is driven hard into a rymered hole in the web of the rail, fixed by means of a nut and washer. The whole is then coated with a tar compound and embedded

Digitized by Google

in the roadway. The rails are connected from the points where they pass nearest the generating station to the switchboard by means of an insulated underground $^{19}/_{12}$ B.W.G. cable, 50 yards long, and the line by four $^{19}/_{15}$ cables drawn into iron pipes. A recording voltmeter, a leakage indicator, and earth-plates are provided at the station in accordance with the Board of Trade regulations.

The cars, constructed by Messrs. G. F. Milnes and Co., of Birkenhead, are five in number. They each measure 22ft. over all, and seat 18 passengers inside and 20 outside. The seats in the interior are longitudinal, and on the roof are of the cross garden-seat type. The bodies are mounted on four-wheel trucks. The diameter of the wheel is 33in., and the wheel base 5ft. 6in. The springs give an easy motion to the car, free from oscillation or pitching. Each car is fitted with one motor. The armatures are drum wound with Eickemeyer coils, the cores being slotted and uninsulated. The whole of the insulation being in the coils, replacement of a defective coil is quickly and cheaply effected. There are 72 sections in the commutator, and four carbon brushes are provided. The magnets are two-pole, iron-clad, and of cast steel, entirely closing the armatures. The speed of the motor is 360 revolutions when the car is running at eight miles an hour. The gear wheels are cast steel, with double teeth helical and single reduction. They are cased in and run in oil. The magnets are spring-suspended from the truck. The total weight of one car fully loaded is 7½ tons, and it is found that this requires a current when running on the level of about 12 amperes. The maximum commercial efficiency of the motor is 83 per cent., and for a considerable range of speed it is over 80 per cent. At eight miles an hour 10 h.p. is developed.

Access to the motor can be obtained either from above, by lifting a trap in the car floor, or when the car is standing over the pit in the car barn, by canting the lower half of the magnets and armature on the axle. The controlling gear is in duplicate, one set being placed at each end of the car on the platform underneath the stairs. The driver stands at the foot of the stairs with the regulating wheel in his left hand, and the wheel brake is within easy reach of his right hand. The spindle of the regulating switch projects from the riser of the third stair. Being interlocked with the reversing switch, it can only be removed when the latter is in the off position. The handle of the reversing switch is on the top of the controller. The resistance consists of 40 platinoid spirals sheathed with asbestos and contained in vertical brass tubes. This construction has the double advantage of giving support to the coils, and, in consequence of there being a considerable mass of material, of absorbing a large amount of heat for short periods. The tubes are insulated from one another by being let into slate bases, and the ends of the platinoid wires are led direct to the switch contacts, so that insulated connections are avoided. The switch has 21 points. The movable contact is made with an iron limb, and is wound with a coil carrying the current from the trolley, and thus a travelling magnetic field is created which blows out the arc at every contact. It is also worthy of notice that when the line current is cut off the motor is short-circuited, and, operating the reversing switch before the car stops, converts it into a generator and pulls up the car. This arrangement takes the place of an emergency brake. The trolley gear is, with some modification in detail, the same in design as that introduced by Mr. A. Dickinson on the South Staffordshire Tramways. It is placed in the centre of the length of the cars close to the side, and mounted on a strong wrought-iron plate well secured to the roof. The cars are lighted by six 16-c.p. incandescent lamps, one being placed fore and aft in the ordinary signal lanterns, one at each side of the car inside, and two on the roof, attached to the trolley pillar.

Without presenting any very striking novelty, the Hartlepools line may be taken as a fair sample of what is requisite to popularise electric traction. As it also shows what can be done without detriment either to appearance or to the convenience of ordinary traffic along the same road, it should be a very fair answer to many of the objections that have been urged against the overhead system.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE ELECTRICAL RESISTIVITY OF BISMUTH.

SIR,—A communication was made on Thursday last to the Royal Society by Prof. Dewar and myself in the form of a letter addressed to the president, of which the following is a copy:

The Royal Institution, Albemarle-street,
London, June 1, 1896.

To the President of the Royal Society.

DEAR SIR JOSEPH LISTER,—In continuing our experiments on the electrical resistance of bismuth at low temperatures and in magnetic fields by the aid of a powerful electromagnet kindly lent to us by Sir David Salomons, we have observed the fact that a wire of electrolytic bismuth when cooled in liquid air to a temperature of −186deg. C. has its resistance increased more than 42 times if it is at the same time transversely magnetised in a field of 14,000 units. The bismuth when cooled in liquid air and thus magnetised has its electrical resistance increased more than 15 times, even when compared with its resistance at ordinary temperatures and not in a magnetic field. There is no reason to believe we have reached the limits of this increase. Reserving further details for a full communication to the Royal Society later, we remain, yours very truly,

(Signed) JAMES DEWAR.
J. A. FLEMING.

It may be interesting to give the exact figures of observation for the information of your readers. The wire of electrolytic bismuth had a resistance of 1·46 ohms at 19deg. C. when not in a magnetic field. If placed transversely to the field in a field having a strength of 14,150 C.G.S. units, its resistance was increased to 2·34 ohms at 19deg. C., or 1·6 times This, of course, is a well-known effect. If the same wire, however, was placed in liquid air and cooled to −186deg. C., its resistance fell to ·53 ohm. If then placed transversely to the field in a field of 14,150 units, its resistance immediately increased to 22·4 ohms, or 42·2 times. Hence, the bismuth cooled to −186deg. C. and in the field of 14,150 has a resistance 15·3 times greater than when at 19deg. C. and not in the field. There is a certain value of the field which just neutralises the diminishing effect of the cooling on the bismuth resistance, and leaves the wire when cooled in liquid air and in the field of the same resistance as when not cooled and not in the field.—Yours, etc.,

J. A. FLEMING.

University College, London, June 20, 1896.

LEGAL INTELLIGENCE.

A WIRING CLAIM.

At the Westminster County Court last Wednesday, before his Honour Judge Lumley Smith, Q.C, the case of Taylor *v.* Titmus was heard.

The plaintiff, an electrical engineer, sought to recover payment of a balance of account for supplying electric light to the defendant's offices in Northumberland-avenue.

The plaintiff's case was that he was asked by the defendant to connect his offices with the mains and fix up four lights. The work was proceeded with, and while it was in progress the defendant paid two sums of £3 each on account without making any complaint, and it was not until payment of the balance of £2. 15s. was applied for that he put forward the suggestion that the charges were excessive.

The **Defendant** was called, and said he was under the impression that the whole of the work would not have exceeded £5, and as he had already paid £6 on account he did not consider there was any further liability. On behalf of the defendant's case, a **Member** of the firm of Dodge and Frazer, electricians, of Cecil-court, was called, and said he considered the plaintiff's charges were too high.

His **Honour** gave judgment for the plaintiff.

ELECTRICALLY-WORKED TIMEKEEPERS.

Last Tuesday in the Chancery Division of the High Court of Justice, before Mr. Justice North, the case of Jardine *v* King, Mendham, and Co. was decided.

Mr. Thomas Terrell, Q.C., and Mr. W. P. Rylands appeared for the plaintiff; and Mr. Bousfield, Q.C., and Mr. C. E. E. Jenkins for the defendants.

In this case, the plaintiff, who resides in Demerara, had taken out a patent for an automatic electric workman's timekeeper, and now sought to restrain the defendants, who have a subsequent patent, from infringing his patent. The plaintiff's instrument is

Digitized by Google

provided with a slot, in which each workman inserts, when arriving at the works, a ticket or metal disc with a number or name for identification. Within the instrument there is a deflector, which in one position guides any ticket inserted in the slot to one compartment, and in another position guides the ticket into another compartment. An electromagnet operated by a clock turns the deflector at a fixed time, so that the tickets of the workmen who come early go into one compartment and those who come after the appointed time go into the other compartment. In the defendants' apparatus tickets are also used, which are placed in a slot, and can, in the ordinary form of the defendants' instrument, drop either into a locked compartment or be returned to the workmen, according as one or another shutter is open. The opening and closing of the shutters is effected by an electric apparatus operated by a clock at an arranged time.

His **Lordship** considered the defendants' contrivances for effecting an object which was not a new object were not within the plaintiff's patent, and gave judgment for the defendants.

COMPANIES' MEETINGS AND REPORTS.

METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Tuesday at Winchester House, E.C., to consider a recommendation of the directors that the capital of the Company should be increased to £1,000,000 by the creation of 50,000 new shares of £10 each. Sir Eyre M. Shaw, K C.B., presided.

The **Chairman**, in moving the resolution authorising the increase of capital, said shareholders would have been prepared by what he stated at their last meeting for the notice they had recently received. Some months ago their chief engineer, Mr. F. Bayley, had laid before the Board his estimates of the Company's probable requirements up to the year 1900. These estimates referred to the new works which were rendered necessary owing to the satisfactory manner in which the demand for electric lighting was being maintained. That increased demand was not only gratifying in that it was large, but it did not come by fits and starts, but continuously, as if it were obeying some law of demand upon the maintenance of which they could rely with confidence, and which had been the main factor in enabling the Board to make their calculations for the future. In addition to this normal progress, which was practically assured, he might remind them of the reduction in the rates of charge to certain classes of customers. The Board had every reason to believe that this concession would be a great boon to a large number of customers, especially smaller tradespeople, who, owing to the regularity of their lighting hours, could be supplied economically, and to whom they were therefore able to offer their lowest current rates. The increase in their lamp density in many portions of their district also warranted their commencing the work of rearranging their system of supply by the creation of transformer sub-stations. From the very commencement of their working the formation of these sub-stations had been kept in view. Special appliances, such as large transformers and concentric mains, with the necessary connections, were requisite for the work, and it had taken some time to bring their manufacture to the present state of perfection. They could therefore confidently look forward to obtaining the best results with absolute certainty, and with a much smaller capital expenditure than would have been the case had they embarked on this undertaking during its experimental stages. In carrying out this development the directors wished it to be understood that the work which had been done up to the present time had not only fulfilled its purpose of maintaining their supply during what might be termed the pioneering period of the Company's history, but the methods then adopted now enabled them to undertake the new work with the greatest facility and with the complete utilisation of their past expenditure. It would be obvious that to carry out these works on the most economical basis it would be necessary to construct them to meet the demands of the Company as they arose from time to time, and to be in a position to take advantage of the most favourable time for making contracts for new machinery and materials. In asking the shareholders, then, to pass the resolution which authorised the increase of the share capital of the Company for the reasons just given, they asked the shareholders to leave it to the directors to issue the proposed new capital at such times and in such amounts as the exigencies of the Company seemed to demand; and they also asked them to leave to the Board's discretion the best method of placing the various issues on the market. It was only after the fullest consideration, and after consulting with those best able to advise them, that they came to the conclusion that, in the interests of the Company, the capital required could be more advantageously raised by the creation of share capital than by any other method. As to the progress of the Company, so little time had elapsed since he last had the pleasure of meeting the shareholders that he had not much additional information to impart as to their present position. He might say that the revenue for the first quarter of the present year amounted to £38,616, as against £31,201 for the corresponding quarter in 1895, or an increase of 23 per cent. The number of lamps connected, which, on the date of the last report—viz., March 17 last—was 272,000, now amounted to 285,000. Before moving the resolution, he would refer to certain letters which the Board had received. While he was most anxious to assure their original shareholders that the Board fully realised how much was due to them, he felt convinced that they would understand that it would be manifestly inexpedient, even if it were possible, for him to tell them the precise terms on which the first or any subsequent issue of the new capital would be made. The conditions under which these issues would be brought out would quite possibly vary to meet the conditions of the market at the time, and he asked, therefore, those gentlemen who had been kind enough to write to accept his assurance that, so far as it was conveniently possible, the interests of the shareholders of the existing capital of the Company should receive the first and best consideration.

Admiral Lord John Hay seconded the resolution.

Mr. John Newton said he would be the last man to offer criticism against directors who had done so much for the shareholders, he had certain opinions as to the issue of shares by directors at such times and at such prices as they might think proper. Shareholders had certain rights, and, in asking them for power to issue the new shares at such times and at such price as they thought proper, the Board were not showing that confidence in the shareholders which the latter had in the directors. He considered that the new shares ought to be issued to the existing shareholders at par, for, if they had to pay a premium on them, the dividend which would be declared would really be less than it seemed. If, for instance, they paid a premium of £2 for their new shares, a dividend on them of 6 per cent. would really be reduced to 5 per cent., and he maintained that this would be to the advantage neither of the shareholders nor of the Company. Their customers, who would look only to the nominal capital, when they found them paying large dividends on that, would think they were being plundered, and there would be an outcry to buy the Company out or destroy their monopoly. He thought it a wrong policy to spring a new issue on the shareholders. At least, some intimation might be given to the effect that within the next six months an issue would be made so that they should not be taken by surprise.

Mr. Billson asked if the directors had considered the question of getting rid of the founders' shares.

The **Chairman**, in reply, said that if the shares were standing at over par, he did not see any reason why the directors should issue them to the shareholders, or anyone else, at par. They would not be justified in issuing them at par when they knew their value was a great deal more. If Mr. Newton wished for further detailed information on the point he had raised, no doubt the auditor, Mr. Griffiths, would be able to satisfy him. With regard to the founders' shares, there was no means of extinguishing those shares unless they had the consent of the founders themselves and a general meeting.

Mr. Newton said that if the directors issued the shares at a premium they could not call it anything but capital, although it might be entered in the books of the Company as premium. Founders' shares were a curse to any company, and if the directors could not deal with them all he could say was that they were not business men. Those founders' shares had a value, and anything of value in the market could be bought. Under the evil influence of the founders' interests large dividends might be earned and, perhaps, paid, to the danger of the Company. If the premium on the new shares were to be used in getting rid of the founders' shares, the question he had raised would be of less importance; but if they began to pay a dividend in excess of 7 per cent., after taking a large premium on new issue of shares, they would raise the question—a fundamental one—as to the respective rights of the holders of the founders' shares and of the ordinary shares.

The **Chairman** pointed out that there was no obligation on the shareholders to take the new shares.

Mr. Newton replied that that was no answer to the point he had called attention to.

Mr. John G. Griffiths (Deloitte, Dever, Griffiths, and Co., auditors of the Company) said Mr. Newton had raised an objection to a course of procedure which was almost universal. If the directors had thought it right to recommend the issue of debentures, debenture stock, preferential stock, or anything which would bear an interest charge in priority to the shareholders' rights, the same result which Mr. Newton regarded as so improper would follow—namely, they would improve the dividends upon the stock of the Company and raise its character as an investment before the public. So far as he might express an opinion in the matter, he would suggest that the price of issue should be such as, while bearing a moderate premium, would tempt the existing shareholders to take up their allotment. But there were shareholders whose means would not permit them to buy that stock however much they might desire to have it, and that being the case he trusted the price of issue would be such that they could sell their right to the allotment of new stock at a moderate profit. To issue the stock at par was practically giving away a large amount of the goodwill which the business of the Company had produced. That premium should go to the credit of the capital account. He thought it would be downright improper, although perhaps not illegal, to put such a premium to the credit of the profit and loss account. It should go to the capital account, and be used as capital for the purposes of the Company.

Mr. Newton said he was not convinced by what had been said, and he desired to move an amendment recommending the directors to issue the proposed new shares at par to existing shareholders.

Mr. Mullett seconded this amendment.

The **Chairman** said he could not accept such an amendment, as it would be out of order, and the resolution was put to the meeting and declared carried, with one dissentient.

Mr. Newton said he would bring the matter forward again.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

ELECTRICITY AT BRIGHTON.

It is but two short weeks ago that the Municipal Electrical Engineers visited Brighton; last week it was the turn of the Borough Treasurers; this week there is a large gathering of Municipal Engineers, whose president is Mr. F. J. C. May, the borough engineer. Surely it cannot be altogether that the Brighton air is so terribly attractive, but more probable that the Corporation possesses able officials whose knowledge and experience is needed by colleagues in their respective associations. We, knowing well these officials both at Brighton and Hove, feel pretty certain that the latter suggestion is the correct one. In these columns we have to deal specially with electrical work, and it is very well known that Brighton was one of the first of the seaside towns to patronise the electric light—in the early days under a company, now under the control of the Corporation. The work has been successful, and large extensions have just been carried out from the designs of Mr. May so far as the buildings, etc., are concerned, and Mr. Wright so far as the machinery is concerned. When, added to the Brighton work, we find that Hove is also provided with a central station, it is not difficult to realise that the householders are real patrons and not pretenders. But Brighton has a further claim to our consideration, in that here Mr. Volk, in 1883, laid down the first electric tramway, which has continued running except during periods of repair or relaying the line. Further, one of the coming attractions is another electric tramway to run between Paston-place groyne and Rottingdean, a distance of nearly three miles. This line is somewhat unique, in that the rails will usually be below the surface of the sea—in some places at high tide the rail level will be fifteen feet below water-level. In our issue of November 8 last we gave some details, with illustrations, of this line. To-day the engineer of the line, Mr. R. St. George Moore, M.I.C.E., will read a paper on the subject of "Electric Traction" to the Municipal Engineers, and in this paper he gives a brief description of the line. There are two or three points in this short paper which may be deemed important. One from an economical point of view may be taken first. At the end of the nineteenth century this country is thickly populated and dependent upon foreign lands for most of its foodstuffs. According to Mr. Moore, "the horses in London would alone consume more than the produce of a million acres of ground." Suppose, then, some form of mechanical motor took the place of the horses, the produce of this million acres might otherwise be utilised. Possibly, instead of feeding horses, it might feed cattle or sheep, and so reduce the importation of meat stuff from other countries. The problem is a big one, but it has another side. This is pleasant to look upon, and may be deemed satisfactory; the other is less satisfactory. If we are to replace horseflesh by means of steam, gas, or electric motors, we shall increase the demand upon our coal supplies. Five-and-twenty years ago alarmists prophesied that the end of the century might possibly see the inhabitants of these islands at their wits' ends for coal.

Digitized by Google

Well, the population has grown, the manufacturing industries have grown, steam locomotion has grown, and the coal supply is not deemed near exhaustion. Certainly the demand has not increased in the ratio of the steam power used, because engines are far more economical than they were, and a horse-power hour is produced with a far less destruction of coal than was thought possible in years gone by. Still, to replace the energy of millions of acres of land is a big request. This side of the question, then, will have to be considered, but we do not think designers and inventors should stop work because of it. Babylon is a howling waste just now, and England may become merely an agricultural and residential property in years to come, but that is no reason why we of the present time should stop the wheels of progress. If the coal stores are exhausted, and we cannot replace that coal nor find any substitute, why then the surplus population must emigrate. Someone might well ask if the million acres are not enough to more than obtain the mechanical motors required to replace the horses. If this question could be correctly answered in the affirmative, then the coal problem might be shelved or solved. Thus Mr. Moore brings us face to face with the question, Will a piece of land of sufficient size to keep a horse produce something else which, if turned into mechanical energy, will replace or more than replace the energy obtainable from the horse? Lastly, for the present some means may be found to obtain more nearly the theoretic energy of the coal than is at present obtainable by means of a steam-engine. Various towns are considering the question of traction, and no doubt will carefully consider the points brought out in Mr. Moore's paper. The London County Council is just considering a memorandum (given elsewhere) of one of its members upon the subject; and though progress may be slow, it seems pretty sure.

ELECTRIC TRACTION FOR TRAMWAYS.

Mr. J. Allen Baker, L.C.C., who is a member of the Highways Committee of that body and of a well-known firm of London engineers, circulated amongst his colleagues a few days ago the following important memorandum detailing the growth, cost, and necessity of electric traction for tramways. An amendment based upon this memorandum was passed by the Council on Tuesday last in preference to the report of the committee:

As a member of the Highways Committee, and taking a deep interest in the subject of the London tramways, I venture under a sense of duty (but not without some hesitation, as a new member of the Council) to present a few facts before my fellow-councillors for their consideration.

Ever since the proposals of the syndicate and of the North Metropolitan Tramway Company have been before the Highways Committee, I have felt how entirely inadequate was either offer to compensate the London ratepayer for his valuable tramway property, and as a natural consequence have consistently opposed in committee the proposals now submitted to the Council.

I urged my committee, before sending forward their report, to make an exhaustive investigation of all the improved systems of electrical and other methods of tramway traction in use on the Continent of Europe and in America, so that we might form an estimate of what our tramways would be likely to produce in the next 14 years if the most suitable of these improvements were adopted, and also what advantages would be given to the public who used the tramway system.

I have felt that our duty is twofold: (1) to obtain the best possible profit for the ratepayers; (2) to obtain the system that will give the greatest satisfaction to the travelling public.

Having visited the principal cities in Canada and the United States during the past few years (including the Pacific coast), and observing the great advance that has been made in the tramway service there, as well as on the Continent of Europe, I have felt that I should not be clear of my own personal duty and responsibility if I did not place before you some of the latest information upon the subject, which I have been able during the past few weeks to obtain.

I append the following figures, which will give the total mileage of electric and other mechanical traction on the Continent of Europe and under construction on January 1, 1896.

	Running January 1.	Under construction January 1.	Total mileage probably now running.
	Miles.	Miles.	Miles.
Germany	245 30	201 73	447·03
France	78·37	38 00	116·37
Italy	24·61	57 00	81·61
England	36·38	13·53	49·91
Austria	44·04	—	44·04
Switzerland	25·24	4·80	30·04
Spain	17·99	11·18	29·17
Algiers	—	22 00	22 00
Belgium	15·45	—	15·45
Norway	4·66	3·10	7·76
Russia	6 20	—	6·20
Servia	6·21	—	6·21
Bosnia	3·47	—	3·47
Roumania	3·37	—	3 37
Holland	1 98	—	1 98
Portugal	1 73	—	1·73
	515 00	351·34	866·34

By the foregoing it will be seen that England is far behind Germany, France, and Italy in the adoption of the recent improvements in tramway traction, and London, which has greater need, and probably greater chances of success than any other city in the world, does not possess a single mile.

Of the 866 miles of electric tramway in Europe, over half is in Germany alone, and it is in this country, after thorough trial and proof of economy, that the most rapid extension is going on.

The example of the United States and Canada is still more striking. Eight or nine months ago it was stated that there were 10,000 miles of electric tramway in operation in North America. It is now estimated at upwards of 15,000 miles.

Hanover has a greater mileage of tramways in proportion to its population than any other city on the Continent. The present tramway company bought up the original three years ago—then paying 1½ per cent.—and now, with 15 miles of electric lines, started 18 months ago, and 34 miles of horse traction, is paying 4 per cent.; and so successful has the electric installation been that all the remaining horse lines are to be converted to the electric system next year.

Hamburg is the first city in Europe to have the whole of its tramways converted to electric traction. It formerly employed 2,600 horses. Many of the streets where the trams run are narrower than those in London and quite as busy. This is the largest installation in Europe, and has been a marked success.

Berlin.—Two test lines are being converted and equipped for electric traction, and it is fully expected that very soon electric traction will supersede horses over the whole 125 miles of the tramway system. The system to be adopted is the overhead and conduit combined.

Milan has a very successfully-combined electric light and electric tramway system. The Corporation decides what routes are to be run and how many cars, also fixing the fares. The charge is 1d. all the way out from the centre, and the company are bound to run special cars one hour each morning and one hour each evening at a fare of ½d.

Paris.—Several systems of mechanical traction are in use in Paris on certain routes, but seeing that the com-

Digitized by Google

pany's leases do not expire till 1907, desirable improvements are not likely to be brought about for some time.

Rouen.—The tramways of Rouen have just been transformed from horse to electric traction, the opening of the latest line being on March 22, 1896. The frequency of the service in 1895 with horse traction was such that two round trips per hour per car were made; whereas in 1896 with electric traction three round trips per hour per car were accomplished. From February 8, 1895, to March 19, 1895, the receipts from horse-car service, *with* 30 *cars* in operation, *amounted to* £2,000; and for the same period in 1896, *with* 32 *electric cars*, the receipts amounted to £3,800. During the period dealt with in these comparisons no change in the fares had been made, the first-class fare being 1½d., and the second-class fare 1d.

These figures show in a striking manner that traffic increases with the adoption of electric traction, on account of it being so much quicker and more attractive and popular.

It is not surprising therefore that a deputation of the Glasgow Corporation, which has recently visited the principal cities on the Continent to inspect their tramway systems, should say: "Our general observation is to the effect that a practically universal move in the direction of substituting electric power for horses is in progress all over the Continent," and should recommend their own Corporation to adopt the most approved electrical system, and this, notwithstanding the fact that it is but a little more than a year since the same Corporation completely installed their own tramway system with new cars and horses.

Nor is it surprising that the enterprising Corporation of Birmingham, after making trial of two other modes of mechanical traction, should decide upon an electric system for their city, the contract for which, I believe, has now been entered into.

Mr. W. H. Preece, C.B., F.R.S., vice-president of the Society of Arts, in speaking of the development of the electrical traction in the United States (see *Journal* of the Society of Arts, March 20, 1896) states: "If the tramway company worked its system by electricity instead of horses, the result would be that *it would cost them about* 1½*d. per mile, instead of* 4*d. for horsepower* . . . He heard that the growth of traffic in Bristol since the introduction of electricity had been very satisfactory, and the same thing had been noticed in America. On the same roads, with the same cars, what was called the factor of public satisfaction, arising from the quicker rate of travelling and other improvements, had increased the amount of traffic by some 30 per cent."

Mr. W. M. Murphy, of Dublin, also states in the same "issue of the above *Journal*, that according to his experience Great Britain was behind the whole world in the matter of electric traction, which could not be better illustrated than by saying that the city of Glasgow, having acquired the tramways a little more than a year ago, bought a new horse plant to work them instead of an electric plant."

The city of Dublin has now a very successful electric tramway system, and the above shortcoming on the part of Glasgow will shortly be remedied.

But it is to the United States and Canada, where electric traction has been longer in vogue than on this side of the Atlantic, that we must look for the greatest advance and the most economical working; and whereas in Europe installations have been so recently installed that comparative figures of the cost of animal and mechanical traction are difficult to obtain, in the United States and Canada definite figures and a basis for estimates is easily arrived at.

I have received from Mr. John Nuveen, a Chicago correspondent, in whom I have the greatest confidence, the following figures as obtained by him from an expert in electrical traction: "The expense of running a 100-car line with horse power per car per mile is usually estimated at 32 cents."

The following is the expense of running electric lines: "Chicago General Railway Company (Twenty-second-street line), 11 cars. Expense per car per mile, 9·7 cents. Expense of running the Cleveland Electric Railway Company, 275 cars, per car per mile, 8·2 cents." I venture to give the following extracts from the *Scientific American*, May 23, 1896: "Operating expenses and cost of equipment: The old horse-car road in large cities operated at a total cost of from 18 to 25 cents per car-mile. One car mile is taken as the standard for operating expenses in our tramways service. The heaviest item in this operating expense was the question of power—that is, the care and maintenance of the horses, their feeding, and the depreciation of same. The average life of a horse on a well-operated tramway road is five to six years, and the number of horses required per car from eight to eleven, according to conditions and requirements. The cost of this power service *was from* 8 *to* 11 *cents per car mile.* This is where the electric road has made its heaviest gains in the reduction of operating expenses. *This item is reduced in* (*electric*) *power service* to-day to a cost, under general conditions, *ranging from* 1 *to* 1½ *cents* per car mile. Is this not a marvellous gain in a few years, and does it not indicate and show the possibilities of the introduction of this power on this service? The relative proportion of operating expenses to earnings in the horse railway service was from 70 *to* 80 *per cent. operating expenses to gross earnings.* In electric service we have a considerable increase in our gross earnings over our old horse line, *which increase runs from* 25 *to* 50 *and even* 100 *per cent.*, in some cases, and the operating expenses being 40 *to* 60 *per cent.* of the gross earnings."

I also give an extract from the report (dated January 14, 1896) of the Metropolitan Traction Company operating the New York tramways: "Mileage operated by cable and conduit underground electric systems, 32·12; still operated by horses, 131·38; total mileage of the company, 163·50. Of the net earnings, more than 73 per cent. came from the mileage now operated by mechanical traction. That is, with four-fifths of the mileage of the system still operated by horses, and therefore undeveloped, the net earnings of the one-fifth thus far improved have been so large as to carry the entire investment. It is not only through an increase of business that this is brought about, but also through economy in operation. When the entire traction system was operated with horses, the cost of the operation was 70 per cent. of the gross receipts. The substitution of mechanical traction upon 20 miles of 122 reduced the cost of operation of the entire system to 54·39 per cent. by the substitution of mechanical traction for horses. These figures indicate very plainly what may be expected of this system when it shall be supplied with mechanical traction throughout, and be in other respects fully developed."

The New York City Corporation has refused the company the privilege of having an overhead system, but New York has been amongst the first to successfully instal the underground or conduit system. Many improvements have been made in this system since the experimental line was started in Budapest a few years ago; and from enquiries made from reliable sources, both in New York City and Canada, I am assured that there is not the least doubt as to the successful and economical working of this system, not only in New York but in other important American cities, and it is stated to be even more economical in working than the overhead trolley system, although more expensive in the cost of installation.

I have no doubt that further improvements will shortly be made in this system of electric traction.

I have also had particulars and description of another system which has just been placed on the market—the "Johnson-Lundell"—which requires no underground conduit at all. It is now working on a short experimental line in New York City. The Westinghouse Electric Company, 32, Victoria-street, S.W., have also introduced a *closed*-conduit system on somewhat the same principle.

The figures given as to the working of the electric system in Toronto, Canada, are very instructive. The company pay to the city a fixed sum per mile and a movable percentage of the gross takings according to the total annual receipts.

Since the establishment of the electric system, the cost of working has been reduced by 30 per cent., and the gross takings or increase of business has increased a like amount of 30 per cent.

The Corporation received last year as its payment from the company the sum of 138,196dol., a sum equal to, say, £28,500.

Toronto has a population of 175,000, and if a like pro-

Digitized by Google

portionate success were obtained in the county of London, which has a population more than 25 times greater, the annual income would be over £712,000 per annum.

The same report (just issued) states that it is estimated that the citizens save by the system of transfer, without extra fare, as much as 100,000dol.—say £20,618—per annum, and although this sum does not go into the city treasury, the citizens get the benefit of it.

The Montreal Street Railway Company shows an equally satisfactory increase in traffic and profits since the conversion to the electric system, as the following extract from the company's published report for 1895 will show: "The cost of operating during the entire year averaged 59·20 per cent. of the receipts, as compared with 82·68 per cent. for 1892 (under horse traction). It is satisfactory in referring to the statistical statement to draw attention to the good result obtained by the conversion of the system to electricity. While the receipts for 1895, as compared with 1892, have grown from 564,406dol. (say, £116,372) to 1,102,777dol. (say, £227,377), the operating expenses have only increased 186,166dol. (£38,384), and the net earnings have increased from 97,761dol. (say, £20,156) to 449,965dol. (say, £92,776). The number of passengers carried has grown from 11,631,386 to 25,877,758. No other company your directors can truthfully say has experienced more gratifying results than these in the conversion of its system to electricity."

I think it will be seen from the foregoing that the earning power of a tramway under usual conditions may soon be doubled by the adoption of the improved systems of tramway traction now in the market, as well as immensely augmenting the satisfaction given to the public, and I believe that the possibilities of London in this direction are equal to those of any city in the world.

The clauses in the proposed agreement with the North Metropolitan Tramways Company—and the fact that the company has a comparatively short lease, and will naturally be desirous of continuing to use their present plant and continue their present system—are not in my opinion at all likely to ensure the improvements that London needs, nor the profit to the ratepayers that this valuable property should yield. I therefore trust that a true estimate of our tramways may be arrived at before we commit ourselves to the entirely inadequate figures that are proposed.

In submitting the foregoing considerations, I would urge that the fullest possible enquiry and examination of the various systems in use on both sides of the Atlantic be made and their value for London ascertained.

I am of opinion that by thus holding our hands until these investigations are made, the value of our property, whether worked by a company or by the Council itself, will not depreciate, but quite the reverse; and it must be acknowledged by all that for the greatest city in the world, whose streets present an ever-increasing difficulty through the congestion of traffic, too much thought and care cannot possibly be given to secure for it the best and most advantageous system that can be obtained.

ELECTRIC AND MAGNETIC RESEARCH AT LOW TEMPERATURES.*

BY J. A. FLEMING, M.A., D.SC., F.R.S., M.R.I.

(Concluded from page 694.)

The chart (Fig. 8) before you shows how the electrical resistance varies between the limits of −200deg. C. and 100deg. C. when the alloy is taken through a cycle of temperature beginning at 100deg. C. in its non-magnetic state. The 29 per cent. nickel steel exhibits the same characteristics in a less marked degree. A close study of this interesting material shows that there is room for much valuable work upon it yet. A manganese steel brought to notice by Mr. R. A. Hadfield, having about 12 per cent. of manganese in it, is also capable of existing in two states—a magnetic and a practically non-magnetic variety. The magnetic variety, which is much more brittle, is, however, in this case, formed by the prolonged slow heating of the non-magnetic variety out of contact with air. In the non-magnetic condition the material has a very high specific resistance at 0deg. C.—about 65,700 C.G.S. units per cubic centimetre; but the magnetic variety has a much lower specific resistance—viz., about 51,400 C.G.S. units at 0deg. C. In all these cases it is interesting to note that the change of the alloy into the magnetic variety is accompanied by a decrease in resistivity or increase in conductivity; in an increase in brittleness. We have tried cooling this non-magnetic variety of manganese steel in liquid air, but have not been able in that way to make any change in its condition as regards magnetic susceptibility. There is a particular alloy of copper 84 per cent., manganese 12 per cent., and nickel 4 per cent., called manganin, which at ordinary temperature exhibits but little change of resistance with change of temperature. On taking the curve of its resistance over wide ranges of temperature, we find that its curve is very concave downwards, and the vertex of the curve lies at about 16deg. C. Hence at ordinary temperatures small changes of temperature make no change in its resistance, but above this point its temperature coefficient is negative, and below it it is positive. All alloys in which a negative temperature coefficient has been observed are probably instances of the same mode of variation of resistance. It may be noted, in passing, that the element manganese when present in an alloy seems to have a great tendency to produce high resistivity and small temperature coefficiency. Returning, then, to the pure metals, we may ask, What is the meaning of the fact that in their case the resistance lines all converge so as to indicate that the electrical resistance would vanish at the absolute zero of temperature? We know that the passage, as we call it, of an electric current through a conductor heats it, and that by Joule's law the rate of production of heat in the conductor

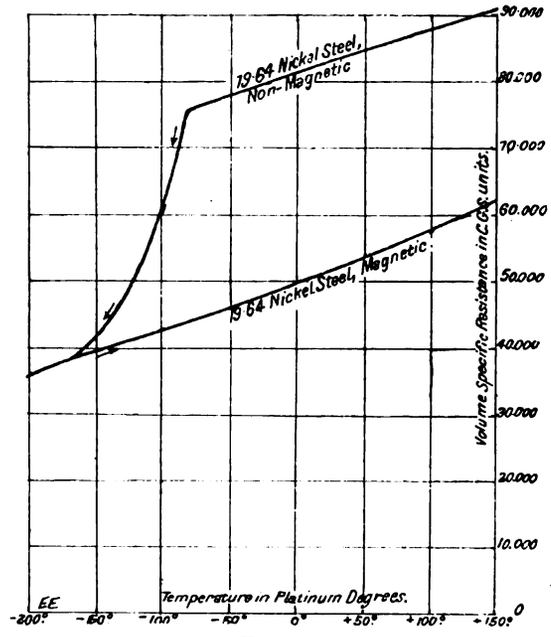

FIG. 8.

is proportional to the square of the current strength and to the total resistance of the conductor. Suppose we take two wires, say, of iron and a certain copper-nickel aluminium alloy, of the same size and length. These wires will, at +100deg. C., have the same resistance. A unit current flowing through them will therefore generate heat in them both at the same rate. Cool them both down, however, to the temperature of liquid air. In the case of iron the resistance is reduced to one-fifteenth of its value at -200deg. C.; in the other case it is only reduced by only 10 per cent. Hence, at the low temperature the alloy dissipates energy for the same current nearly 13½ times as rapidly as the nickel.

It is a logical deduction from all we know to conclude that if we could reach the absolute zero of temperature, the pure metal would not dissipate the energy of the current at all. Imagine two iron wires, then, stretched through space, say, from the earth to the moon, and kept everywhere at the absolute zero of temperature. We could transmit any amount of electrical energy along them without dissipating any of it as heat in the wires. As a consequence of this, any pure metal cooled to the absolute zero of temperature would become a perfect screen for electromagnetic radiation, and would be perfectly impenetrable to electromagnetic induction. We can show this increase in the power of electromagnetic screening by metals when cooled in the following way: A suitable coil of wire is placed between the poles of an alternating-current magnet and a small incandescent lamp connected with the coil. When the magnet is excited it induces currents in the coil, and the lamp glows up. A cap of aluminium is made of such a size as to drop easily over the coil. This aluminium is not of sufficient thickness or conductivity to screen off the induction when it is warm. If, however, we cool the aluminium cap in liquid air and then

* A Friday evening discourse delivered at the Royal Institution, June 5, 1896. Lord Kelvin in the chair.

Digitized by Google

drop it over the coil, the lamp for one instant goes out, but it comes in again as the metal cap instantly warms up. This shows us, however, that if the cap were at the absolute zero of temperature it would be a complete screen for the induction. In fact, these experiments furnish us with a new definition of what we mean by the absolute zero of temperature. It is the temperature at which perfectly pure metals cease to have any electrical resistance.

In the conduction of currents at ordinary temperatures, as we generally know it, two effects are inseparably connected with the conveyance of energy by this process. One is the dissipation of some of the energy as heat in the conductor, the other is loss of potential or fall of electric pressure, and which is one of the factors in the equivalent of the energy so dissipated. If, however, the conductor is at the absolute zero of temperature, there is no dissipation of energy in it, and neither of these consequences would be present. There would be no heat produced in the conductor and no fall of potential along it either for large or small currents. What, then, under these conditions is the function of the conductor? The answer is that it becomes a mere boundary, serving to limit the electromagnetic field and determine the direction in which the energy transmission is taking place. These experiments, therefore, may be regarded as forging one more important link in that chain of evidence which compels us to look for the processes concerned in the conveyance of energy by an electric current, not inside the conductor,

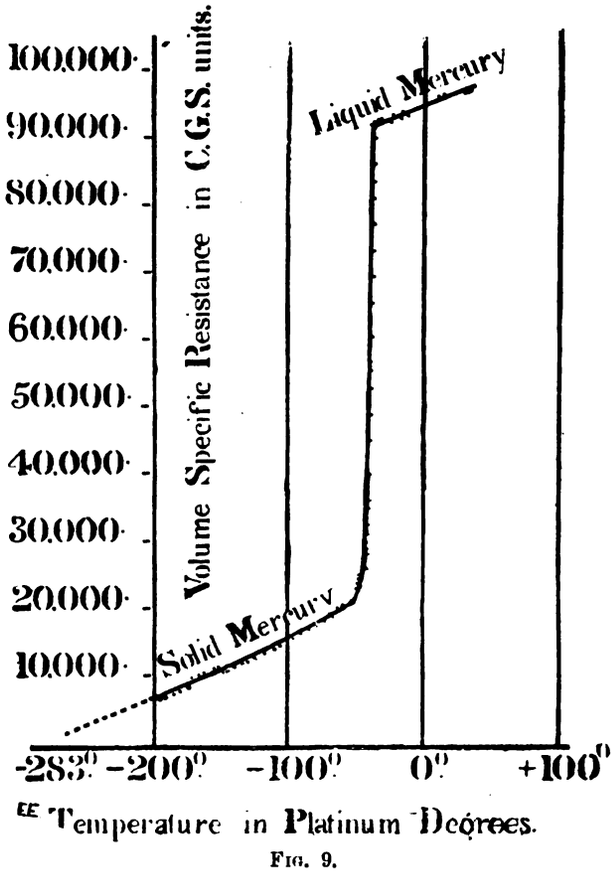

FIG. 9.

as we call it, but in the dielectric, or medium outside. We may, then, ask how is it that different bodies have such various dissipative powers when acting in this way as the boundary of an electromagnetic field? The only suggestion on this point I venture to make here is as follows: Materials of high specific resistance have all probably a very complex molecular structure. The alloys of high resistivity are not probably merely solidified mechanical mixtures of metals, but chemical compounds; and even in the case of elementary bodies like carbon and sulphur they may have, owing to their high valency, and tendency of their atoms to auto-combination, a complex molecular structure. This structure may bestow upon them the power of taking up energy from the electromagnetic medium, just as gases with a highly complex molecular structure are very absorbent of radiant heat, which, if the electromagnetic theory of light is true, is only another form of electromagnetic energy. All we know at present about the processes at work during the time a conductor is traversed by an electric current is that there is a magnetic field outside the conductor and also within the mass of the conductor, and that some mechanism is at work absorbing energy through the surface of the conductor and dissipating this as heat in the interior. The resistance of a conductor is best defined as the number expressing the rate at which it dissipates electromagnetic energy per unit of current. For the same current—that is, for the same external magnetic field—conductors dissipate this energy at very different rates. Some, like silver and copper, which have the lowest rates, are elements of low valency and molecular volume, and have probably a simple molecular structure. Others, like alloys of high resistivity, have in all probability a more complex molecular structure. Both this last, as well as the molecular mobility characteristic of the liquid state, are conditions which bestow the power of taking up rapidly and dissipating the energy of the electromagnetic field, and this has to be kept supplied from energy-transforming sources. We cannot, however, at present construct profitably further mechanical hypotheses to account for this difference in the presence of our great ignorance about ether, molecules, and energy.

In passing from the liquid to the solid state there is generally an immense increase in the conducting power of metals. This is well shown in the case of mercury. A glass tube a metre in length was formed into a spiral coil and fitted with pure mercury, suitable connections being provided at the ends. This coil was embedded in a mass of paraffin wax, and a platinum-wire thermometer placed in contact with it. The whole mass was then reduced to the temperature of liquid air, and observations taken of the resistance of the mercury as it heated slowly up after being removed from the liquid air. The curve in Fig. 9 shows the manner in which the resistance increases with great suddenness between 41deg. and 36deg. as the metal passes into the liquid condition. The resistance becomes four times greater between −50deg. and −36deg. in the course of 14deg. rise of temperature, and whilst in the act of passing through the melting point of the mercury at −38·8deg. C. This chart shows that the resistance of the mercury in the solid state tends downwards, so as to indicate that its resistivity would completely vanish exactly at the absolute zero of temperature. It is interesting to note also that the portion of the resistance curve belonging to mercury in the solid state is sensibly parallel to that portion of it in the liquid state.

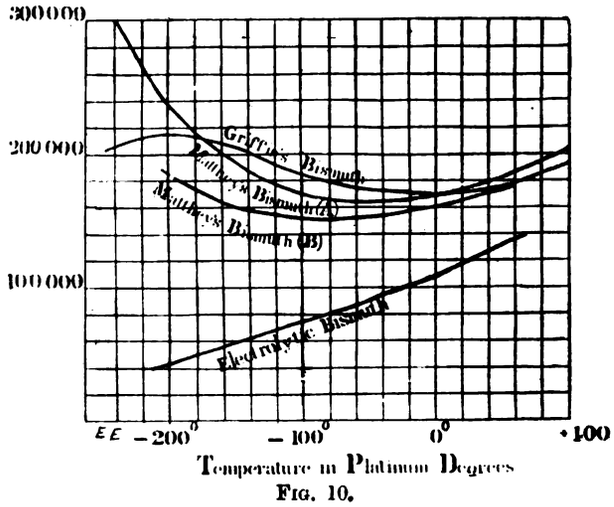

FIG. 10.

We carried on a long struggle with bismuth in the endeavour to unravel some of the electrical peculiarities of that metal at low temperatures. Chemists are aware of the extreme difficulty of preparing bismuth in a state of perfect chemical purity by purely chemical means. From several different sources we procured bismuth which had been carefully prepared by the reduction of the oxychloride, or nitrate, after careful reprecipitations. This bismuth was then pressed into wire, and its resistance curves taken down to the lowest attainable temperatures. We found some very extraordinary results. Although sensibly agreeing in resistivity at ordinary temperatures, in two cases the resistance curves had a minimum point, and after reaching this at about − 80deg. tended upwards again, showing that the resistance was increasing as the metal was further cooled. These curves could be repeated as often as necessary with these samples. Another specimen gave a curve with a double bend (see Fig. 10). These results convinced us that it would be necessary to prepare bismuth electrolytically, and with the assistance of Messrs. Hartmann and Braun, of Frankfort, who have made a special study of the preparation of electrolytic bismuth, we were provided with a quantity of the metal, which examination showed to be chemically pure. On taking the resistance curve of a sample of the electrolytic bismuth when pressed into uniform wire under great pressure, we found that its behaviour was perfectly normal, and that the resistance line tended downwards, as in the case of all other pure metals, to the absolute zero. Also we found that the specific resistance of this last very much less than that of the chemically-prepared samples, and less even than that employed by Matthiessen. Hence, *pure* bismuth is no exception to the law enunciated above. Bismuth is characterised especially by many peculiarities. It has been known for some time that the resistance of a bismuth wire is increased

Digitized by Google

when it is placed in a magnetic field so that the lines of the field are perpendicular to the direction of the current flow. This is easily shown by means of one of Hartmann and Braun's spirals, manufactured now purposely for measuring magnetic fields.

We have, however, discovered that if bismuth is cooled to the temperature of liquid air, the effect of any given magnetic field in changing its resistance is increased many times. Thus, for example, a certain bismuth wire we used had a resistance of 1·690 ohms at 20deg. C. Placed in a magnetic field of strength 2,750 C.G.S. units, its resistance was increased to 1·792 ohms, or by 6 per cent. The wire was then cooled in liquid air, and its resistance lowered to 0·572 ohm. On putting it then into the magnetic field of strength 2,750 C.G.S. units, its resistance became 2·68 ohms. Hence, it had increased 368 per cent. This magnetic field can then actually reverse the effect of the cooling and cause the bismuth, when cooled and magnetised, to have a greater resistance than when at ordinary temperatures and unmagnetised. We are at present engaged in further unravelling the problems presented by this new discovery with regard to bismuth. It is certainly very startling to find that a magnetic field which increases the resistance only 5 per cent. at ordinary temperatures increases it five times at - 186deg. C. It will be seen that this process of taking the resistance of a conductor in liquid air is one which affords us a very critical means of discrimination as to the chemical purity of a metal. It ranks almost with the spectroscope as an analytical method.

Time will only permit one brief reference to the behaviour of carbon in regard to electrical conductivity when cooled to low temperatures. We have found that carbon in the form of carbon filaments taken from various incandescent lamps continued to increase in resistance as it was lowered in temperature. The resistivity at various temperatures of the carbon from an Edison-Swan lamp at various temperatures is as follows:

C.G.S. units.	Temperature.
$3{,}835 \times 10^3$ at	99° C.
$3{,}911 \times 10^3$,,	18°·9 C.
$3{,}953 \times 10^3$,,	1° C.
$4{,}054 \times 10^3$,,	- 78° C.
$4{,}079 \times 10^3$,,	- 100° C.
$4{,}180 \times 10^3$,,	- 182° C.

These values when represented on a chart give almost a straight line, and show that the resistivity of carbon continually increases as it is cooled, but at a very slow rate. The temperature coefficient is therefore negative, and of about the same absolute magnitude as many alloys of high sensitivity. The resistivity of this form of carbon is about three thousand times that of silver. Adamantine carbon taken from a Woodhouse and Rawson lamp had a resistivity 50 per cent. greater.

All the so-called insulators—*e.g.*, glass, guttapercha, ebonite, paraffin—have resistivities enormously greater than that of carbon, but, like it, their resistance increases as the temperature is lowered. For the sake of comparison we have placed upon this chart of lines of metallic resistivity the resistance line of carbon, with ordinates drawn to a scale of one-hundredth part of those of the metals. To properly represent to the full scale the line of carbon, this chart, which is 15ft. long, would have to be made one-third of a mile long. If we desired to represent on the same scale the resistivity of guttapercha, the length of the chart would have to be billions of miles; in fact, so long that light would take 5,000 years to traverse it from one end to the other. Even then, to represent to the same scale the resistance lines of paraffin and ebonite, it would have to be 30 or 40 times longer.*

We must next pass on to consider some problems in thermo-electricity which have engaged our attention. If we construct a thermo-electric couple of two metals in the form shown in the diagram (see Fig. 11), and connect this with a galvanometer, and if one junction is kept at a constant temperature—say 0deg. C.—whilst the other junction is heated or cooled to various temperatures, we shall in general, but not always, find an E.M.F. acting on this circuit when the junctions are at different temperatures. This E.M.F. depends on three things—the nature of the metals, the temperatures of the junctions, and on a certain temperature called the neutral temperature of the metals. An important matter in the experimental theory study of thermo-electric action is to discover the position of these neutral temperatures when different metals are tested with lead as the standard of comparison, and when one junction is kept at 0deg. C. Elaborate experiments made by Prof. Tait many years ago furnished full information on this matter for temperatures lying above 0deg. C., and we especially desired to extend this knowledge to ranges of temperature between 0deg. C. and -200deg. C. Accordingly a number of thermo-electric junctions were prepared of various pure metals and alloys, the comparison metal being always pure lead. These couples were grouped together, and one set of junctions always kept at 0deg. C. in melting ice. The other sets were cooled to various low temperatures by means of liquid air. The experimental process then consisted in measuring the E.M.F. set up in each length respectively, and at the same instant measuring the temperature of the low-temperature junction. After various failures a device was adopted for making this double measurement with great accuracy and expedition. The arrangement consisted of a combined potentiometer and resistance balance. A long uniform wire, stretched over a scale, had a battery connected to its two ends so as to make a fall of potential down the wire, which could be regulated by appropriate resistances. It will be easily seen that we can combine a galvanometer and resistance coil with this arrangement in such a manner as to form it into a Wheatstone's bridge or a potentiometer. In this latter form of instrument an unknown E.M.F. is balanced against the known fall of potential down a certain length of a graduated wire, and a galvanometer employed to ascertain the point on the slide wire at which this is the case. Omitting details, it may be stated that we succeeded in devising an arrangement of circuits in which this change from a potentiometer to a resistance bridge was effected by moving two brass plugs from one pair of holes to another. This instrument formed a combined resistance and E.M.F. measurer which enabled us to do two things: first, to measure the E.M.F. in any thermo couple; secondly, to measure the temperature of the low-temperature junction by measuring the resistance of a platinum wire wound round that junction and acting as a thermometer. In actual practice the platinum thermometer consisted of a small hollow copper cylinder. In the interior of this cylinder were inserted a number of the thermo junctions, and round the outside was wound the platinum thermometer wire. Aided by this device we were able to measure temperatures with an accuracy of 1-25th of a degree at a temperature of -200deg. C., and to ascertain at the same instant the exact E.M.F. acting in the couple. When these arrangements had been perfected, the method adopted was to put one set of the junctions in melting ice. The other set, enclosed in the copper cylinder, were embedded in a mass of paraffin wax, which was then cooled down to the temperature of liquid air. The mass was then removed and inserted in a vacuum vessel and allowed to heat up very slowly. At frequent intervals during the heating the E.M.F. of the couple was taken, and also the temperature of the junction.* The events which under some conditions

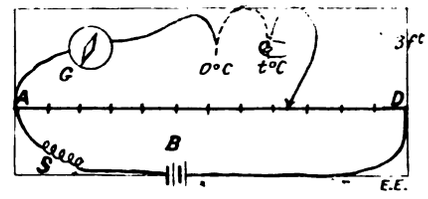

FIG. 11.

happen in the case of a platinum-lead junction can easily be shown, and are very interesting. At the first immersion of one junction in liquid air whilst the other is in melting ice, we get a current, as shown by the galvanometer, in one direction. On lifting one junction out of the liquid air it begins to warm up. The first effect of this heating is to reduce the thermo current in the circuit. At about - 111deg. on our platinum scale—some distance, therefore, above that of liquid air—the current in the circuit falls to zero. As the junction continues to heat up, the current increases again in the opposite direction. At about -60deg. the low-temperature junction reaches the temperature called the neutral temperature, and the current is a maximum in one direction. It then begins to fall off once more, and it finally becomes zero again when the two junctions are both at the temperature of melting ice, and it, lastly, increases in the opposite direction as this variable junction continues to warm up from 0deg. C. to higher temperatures.

Having carried out the observations described with all our thermo couples, the results were represented in a chart† as follows: A horizontal line was taken on which were marked off divisions representing platinum temperatures; vertical ordinates were then drawn at various temperatures for each couple representing the E.M.F. on the couple when the cold junction was at the temperature denoted by the abscissa of that ordinate. In this way a series of curves were delineated which all passed through the point representing 0deg. C. These curves are the curves of thermo-electromotive force. In Prof. Tait's researches on this subject he adopted a method of representing the facts which has many advantages. Suppose the couple to have one junction at a constant temperature and the other to be varying. At any instant the E.M.F. of the couple is varying at a certain rate with the changing temperature of the non-

* The resistivities of platinoid, carbon, and guttapercha at 0deg. C. are nearly in the ratio of the numbers 4×10^4, 4×10^6, and 4×10^{23}.

† This was given in error in our last number as Fig. 7.

Digitized by Google

constant junction. This rate measures what is called the thermo-electric power of the metals with respect to each other at that temperature. If we measure the slope of the E.M.F. curve at any point, it can easily be shown that the numerical value of this slope gives us the rate of change of E.M.F. with temperature. If we plot these slopes in terms of the corresponding temperature, we obtain another set of curves called curves of thermo-electric power. Lead is always taken as the standard metal for comparison because the Thomson effect in lead is zero. From our chart of thermo-electromotive forces we have constructed another one of thermo-electric powers. The lines of thermo-electric powers cut the lead-line in various places, and the temperature at which they do this is called the neutral temperature of that metal with respect to lead. Prof. Tait deduced from his experiments that these thermo-electric lines were straight lines for temperatures above zero Centigrade, and he made, in addition, the important discovery that for certain metals, such as iron and nickel, the thermo-electric lines have sudden changes of direction at high temperatures.

The general result of our investigations at low temperatures is to show that whilst in some cases the thermo-electric lines are approximately straight lnes for temperatures down to the lowest reached, they are not all by any means straight lines. In some cases, such as iron and bismuth, we find sudden changes of direction of the thermo-electric lines similar to those found by Prof. Tait at higher temperatures, and this indicates a change in sign in the Thomson effect at that point. Moreover, in many cases there is a decided tendency of the lines of many metals to bend round in a manner which indicates that their thermo-electric power probably would become zero at the absolute zero of temperature.

The temperature at which the thermo-electric line of any metal crosses the line of lead gives us the neutral temperature of that metal with respect to lead, and at that temperature the metal is thermo-electrically identical with lead. If one junction of a couple is at a temperature as far above the neutral temperature of the metals as the other is below it the couple will give no E.M.F. This provides us with an experimental method of determining the position of certain neutral points. Thus, for instance, if one junction of a platinum-zinc couple is placed in liquid air and the other is raised to about 30deg., we get no E.M.F. from that couple. This indicates that the neutral temperature of platinum and zinc is about −85deg., and this is shown to be the case from the chart. Two general conclusions are arrived at from a study of the thermo-electric lines as laid down in our chart. The first of these is that the thermo-electric lines of many metals are by no means straight lines over extreme ranges of temperature. Hence the thermo-electric power is not simply a linear function of the absolute temperature. The second important fact is that in the thermo-electric lines of certain metals at low temperatures there are sudden changes of direction, which indicate a change in the sign of the Thomson effect in that metal, and probably, therefore, some important molecular change at the corresponding temperature.

Leaving the further elaboration of these points, we must next notice some of the facts with respect to the magnetisation of iron at low temperatures. Prof. Dewar mentioned in a discourse on the scientific uses of liquid air some results obtained on cooling small steel magnets. These effects we have since again explored by us at greater length. Let me show you in the first place the effect of cooling a small steel permanent magnet to the temperature of liquid air. We will first take a magnet made of knitting-needle or ordinary carbon steel, and examine the effect of low temperature upon it. Placing the magnets behind the small suspended magnetic needle of a magnetometer, we obtain a deflection of the magnetometer needle which is a measure of the magnetisation of the magnet causing the deflection. On bringing up a small vessel of liquid air and immersing in it the magnet under test, we notice at once a sudden decrease in the deflection of the magnetometer needle. This indicates that a notable percentage of the magnetisation of the magnet has been removed. On taking away the air bath and allowing the magnet to heat up again, we find that there is a still further decrease in magnetisation. On cooling it again with liquid air the magnetisation increases, and from and after that time the effect of the cooling is always to increase the moment of the magnet, and the effect of heating it up again always to decrease the moment of the magnet. Hence we see that the effect of the first immersion in liquid air was to give a shock to the magnet which deprives it permanently of a considerable percentage of its magnetism, but when once it has survived this treatment, then cooling it strengthens the magnet and warming it weakens it. This is not by any means always the case. If we take a magnet made of the 19 per cent. nickel steel, the peculiar characters of which were explained a few moments ago, we shall find a very different state of affairs. Here we see the first effect is, as before, to remove a very considerable percentage of the initial magnetisation, but after that stage is passed, then cooling this nickel-steel magnet always weakens it still more and warming it up again strengthens it. The subsequent effect of cooling is therefore in the opposite direction in the carbon steel and in this nickel steel.

We have in this way examined the behaviour of magnets made of a very large number of steels—chromium steels, aluminium steels, tungsten steels, silica steels, and nickel steels in various states of temper hard and soft. We find that in some cases there is no initial decrease of magnetism at all, and that the steady state begins at once. Broadly, however, the results amount to this: a steel magnet when plunged into liquid air generally loses some fraction of its magnetisation, but that after a few such immersions it arrives at a fixed condition, in which the effect of cooling it is in most cases to produce an increase of magnetic moment, but in a few exceptional cases to produce a decrease of magnetic moment.

In the technical use of magnets for instrumental purposes they have to go through a process called *ageing* to get rid of the sub-permanent magnetism. One of the best ways of ageing a magnet is to plunge it several times into liquid air. We have given a large amount of attention to a study of the changes taking place in the magnetic qualities of soft or annealed and also hard iron when cooled to very low temperatures. In the first place, we have examined the change in the permeability of iron at the temperature of liquid air. If a ring of iron is wound over with a coil of wire and subjected to gradually increasing magnetising forces, this produces magnetisation in the iron, but the magnetisation does not increase proportionately with the force.

FIG. 12.

It tends to a limit, and the curve which shows this variation is called a magnetisation curve. The number which expresses the ratio of the magnetisation to the magnetising force is called the susceptibility of the iron. Instead of considering the magnetisation of the iron as one of the variables, it is often convenient to consider the induction in the iron, and the induction is defined as a quantity the rate of change of which with time measures the E.M.F. set up in a secondary circuit wound round the iron ring.

The ratio between the induction and the magnetising force at any instant is called the permeability of the iron. By tedious experiments with the ballistic galvanometer, it is possible to draw out a complete magnetisation curve of the iron, starting from the lowest induction up to the point at which the iron becomes practically saturated. Assisted by Mr. J. E. Petavel, who has given us most valuable help in these very tedious magnetic observations, as well as the subsequent reductions of them, we have made a large number of observations on the permeability of a carefully annealed iron ring made of very fine

Digitized by Google

Swedish iron of the highest quality* (Fig. 12). The result is to show, as seen from the curve (Fig. 13), that cooling the iron to −200deg. slightly diminishes the permeability. In other words, it requires a greater magnetic force to produce a given amount of magnetisation when the iron is at −200deg. than when it is at the ordinary temperature. When, however, we began to study the behaviour of hardened iron in this respect, we found ourselves in the presence of very curious effects. If pure iron which has been carefully annealed is twisted, knocked, bent, stretched, or compressed, it passes into a state known as hard iron; and hard iron has very different magnetic qualities from soft iron. A very extended series of experiments with rings of hard iron have shown that hard iron, at least in certain cases, has its permeability greatly increased by cooling; and this change takes place with great suddenness. We can show you by a simple experiment that this is the case. If we take this hard iron ring, which has two coils of wire wound round it, and connect one of these circuits to a battery, we shall send a current

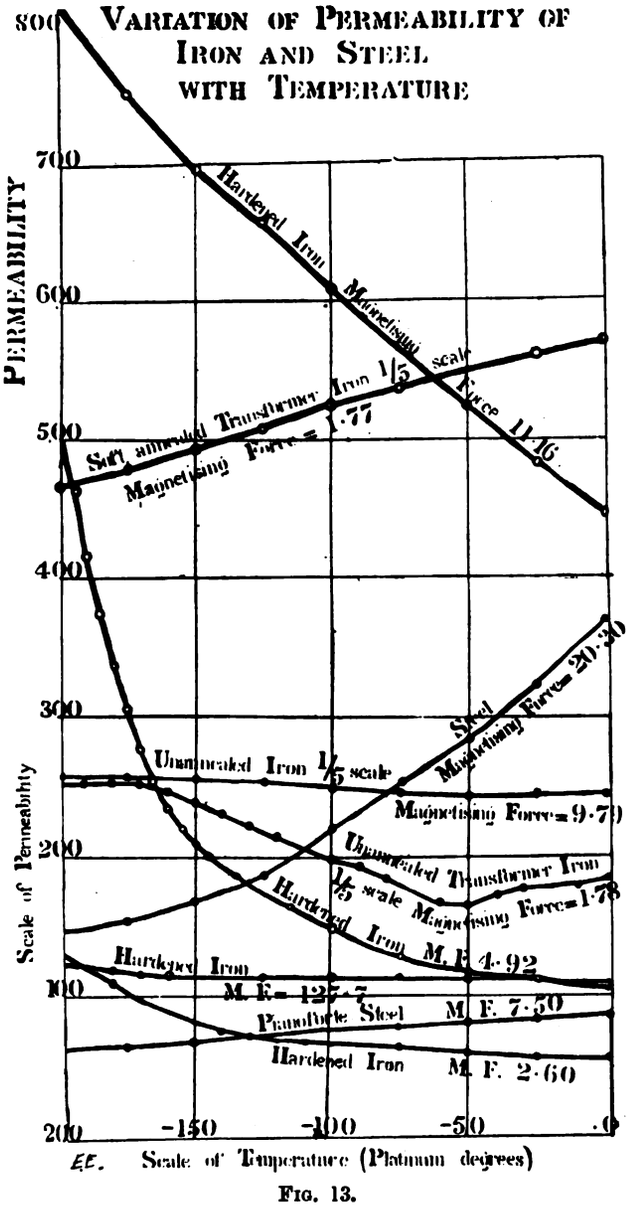

FIG. 13.

through this primary coil and magnetise the iron ring. If the other or secondary circuit is connected to a galvanometer, then at the instant of starting the primary current there is a transitory induced current produced in this secondary circuit. As long as the induction in the iron remains constant, no electric change will take place in this secondary circuit. If, however, we plunge the iron ring into liquid air, we find again a secondary current produced at the moment of cooling the iron. This indicates a sudden increase of permeability at the instant of cooling. If we bring the ring out of the liquid air we find it retains some of the increased permeability acquired on cooling, but loses a portion of it more slowly if it is heated up again to ordinary temperatures by plunging it into a bottle of alcohol. Owing to these changes we found it impossible to repeat again exactly any required magnetisation curve in the case of the hard iron. The sudden cooling alters the magnetic qualities of the iron to such an extent that it is not possible to get it twice in exactly the same state.

By subjecting a hard iron ring to frequent reversals of the same magnetising force whilst it is cooled up slowly from the temperature of liquid air up to ordinary temperatures, we have been able to trace the gradual decrease of the permeability at any constant force throughout this range of temperature.

We have found, on the other hand, that unhardened steel pianoforte wire behaves like soft annealed iron.

We have, then, examined the hysteresis of iron at low temperatures (Fig 14). As the meaning of that term was very fully explained by the inventor of it in a discourse given quite recently, no time need be spent in an elaborate explanation of it. It is sufficient to say that when iron is magnetised and demagnetised or carried round a cycle of magnetisation in which its direction of magnetisation is first in one direction and then in the other, this process involves the expenditure of energy, and such dissipation of energy is spoken of as the hysteresis loss in iron. It would occupy too much time to attempt to explain in full detail the manner in which this dissipated energy can be measured. As a matter of fact, the method we adopted was the laborious but exact one of delineating a complete magnetisation curve of the iron, by means of observations taken with the ballistic galvanometer for various maximum values of the magnetising force. In this way we were able, finally, to arrive at a curve which represented by its ordinates the value of the hysteresis loss in the iron in ergs per cubic centimetre per cycle, and the abscissæ the maximum value of the corresponding magnetic induction.

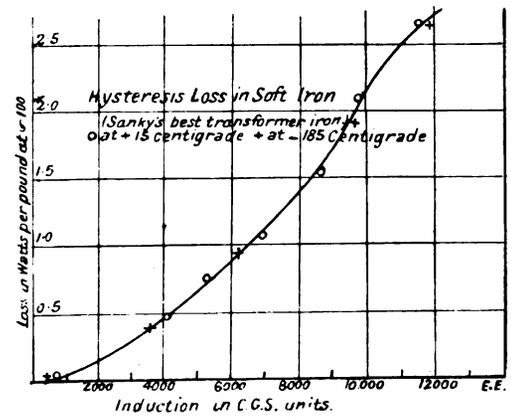

FIG. 14.

When curves had been drawn out from all the many hundreds of observations for the case of the same soft-iron ring at ordinary temperatures and at the temperatures of liquid air, we found little or no sensible difference between them. The result is, then, that there is no appreciable change in the magnetic hysteresis loss of very carefully annealed soft Swedish iron when cooled to these low temperatures. With regard to the hard iron, although the permeability is increased, it is most difficult to say yet whether the hysteresis is increased or not, as every fresh reduction in temperature of the iron alters its physical state, and makes it almost impossible to obtain similar repeated measurements.

It is natural to enquire how far accepted theories of magnetic action are able to reconcile the above-mentioned results. Some of them undoubtedly are in accord with deductions from received hypotheses.

It is generally considered that the facts connected with the magnetisation of iron indicate that each molecule—or, perhaps, small groups of molecules—of the iron are complete micro-magnets, and that in the unmagnetised condition of the iron these molecular magnets arrange themselves in groups or in closed circuits; so that for each little group the external magnetic action or magnetic moment is approximately zero. Magnetisation consists in arranging the members of some or all of those groups so as to collineate the direction of more or less of the molecular magnets and produce an external resultant magnetic moment.

Let us, then, consider one such little group by the aid of a model made of small magnets (Fig. 15), such as Ewing has suggested and used. Suppose the members of this group to be at a certain distance from each other, and we apply a given magnetising force which is just sufficient to open out the group and co-lineate the magnetic axes of the several members of it. Next, suppose we cool this iron; this would result in bringing the members of the group into closer contiguity. The result of this will be an increase of the interpolar magnetic forces of the different members of the group, and as we can see from the behaviour of the model, it would require a greater magnetic force to effect the same amount of collineation of the molecular magnets. This, however, corresponds with what we find to be

* It is only right to add that in other portions of this work we have been much indebted for persevering assistance to Messrs. J. and D. Morris, and in lesser degree to Messrs. Jakeman and Tilney for help in observations requiring several simultaneous observers.

Digitized by Google

the case on cooling soft iron to very low temperatures. Prof. Dewar's experiments have shown that the tensile strength of iron and steel is increased to about double on cooling to – 182deg. C., and it is quite reasonable to suppose that this is the result is in part at least due to an approximation of the molecules.

As regards the behaviour of magnets when cooled, it is highly likely that when the groups of molecular magnets have been opened out more or less that some of these are in a condition of instability, in which bringing the members of the group nearer together will have the effect of making them close up again into magnetic circuits of no external action. Hence, if this is the case, the first effect of the sudden cooling will be to effect the change. These half-hearted groups of molecular magnets constitute the sub-permanent magnetism which it is our desire to get rid of in ageing a magnet. Then, as regards the effect of temperature changes on the magnet when the stable condition of affairs is reached. In order to explain this, I think we must consider the action of the molecular groups upon each other. The approximation of molecular groups will in general, after the magnet is aged, have the effect of collineating more completely the different members of the groups, and hence increase the magnetic moment of the magnet, whilst the separation of the molecular groups and the reverse effects ensue on heating.

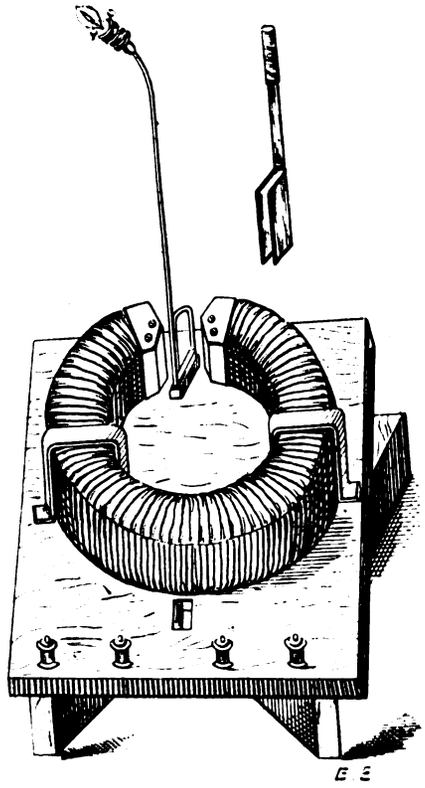

FIG. 15.

The action of the low temperatures upon soft iron and upon magnetised steel would be explicable if we may legitimately make the assumption that lowering the temperature approximates the molecular groups and also the members of each group. The result of this in the case of existing permanent magnetisation is to close up more or less those groups which are in an unstable condition, but it increase the collineation in those groups in which the magnetic moment exceeds a certain value. Hence, in the case of the permanent magnet the first effect of sudden cooling is a compound effect; it consists in a great reduction of the magnetic moment of certain unstable groups, but in an increase of moment of others. After this initial stage is past the normal effect is an increase of magnetic moment of the groups by bringing them closer together and a diminution by increase of distance.

There remains, then, to be explained the anomalous behaviour of nickel steel and hardened iron, but the attempt to throw an inner light upon the results attained with these substances cannot possibly be successful until we have explored far more thoroughly at low temperatures the changes in their mechanical as well as magnetic qualities. However much we may be tempted to speculate upon the causes of these various changes in the properties of matter at very low temperatures, a much more important duty at the present time is the collection of facts and the completion of accurate quantitative measurements. The experimental difficulties of this low-temperature research are very great, but both Prof. Dewar and I have been chiefly anxious in this particular work to prosecute preliminary explorations into as many regions of it as possible, those pioneering experiments enabling us to ascertain in what direction further enquiry will be profitable. Every step forward opens up fresh suggestions for investigation and, I may add, fresh difficulties. In the light of the results, however, thus ascertained we shall have additional means of testing and judging existing electrical theories, and the facts themselves when built into the fabric of scientific knowledge will serve to broaden those foundations on which we may profitably erect new hypotheses of electric and magnetic phenomena, which, even if they cannot dissipate entirely that mystery which enshrouds even the most familiar facts, will serve as a continual stimulus to thought and work in days and years that are yet to come.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ecija (Spain).—The Municipal Authorities of Ecija want tenders by July 2 for a system of electric lighting for the town.

Bucharest.—The Municipality want tenders by July 1 for the electric lighting of a portion of the Boulevard Coltzea. The estimate is about £3,680.

Utrera (Spain).—Tenders are wanted by the Municipal Authority of Utrera for the installation of electric lighting. The last date for receipt of tenders is July 1.

Prestwich.—Tenders for putting into thorough repair the existing telephone system and electric bells at the county asylum, Prestwich, are invited. Full particulars on application at the asylum.

Bucharest.—Tenders will be received up to August 8 by the Roumanian Government (Department of Posts and Telegraphs) for the electric lighting of the new Posts and Telegraph building at Bucharest.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31.

Spandau.—Tenders are wanted at the Royal Small-Arms Factory for 900 incandescent electric lamps by July 17. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21), Spandau.

Cazeres-sur-Garonne (France).—Tenders will be received up to June 28 for electric lighting and water supply work and buildings. The estimate is about £2,043. Applications should be made to the Mairie, Cazères-sur-Garonne, Haute-Garonne.

Brussels.—Tenders will be received shortly (the exact date is not yet announced) at the Brussels Bourse for the material and work necessary to start an electric lighting installation at the fifth section of the central locomotive construction works at Malines.

Karlsruhe.—The management of the Baden State Railways at Karlsruhe are prepared to receive tenders up to July 25 for an installation of the electric light at Bretten Station. Particulars are obtainable for 8 marks (8s.) from the Centralbureau der Generaldirektion, Grossh. Badische Staatseisenbahn, Karlsruhe, Germany.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality Tenders must be submitted by September 1 next Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Battersea (London).—The St. Mary's Vestry will receive tenders up to July 14 for a complete installation of the electric light for the town hall and municipal buildings. Specifications and conditions can be obtained from Mr. R. Hammond, Ormond House, Great Trinity-lane, E.C., after a deposit of two guineas has been made with the Vestry Clerk, at the Vestry Offices, Lavender-hill, S.W. Clauses for the payment of trades union wages will be embodied in the contract.

Huddersfield.—Messrs. Learoyd Bros. and Co invite tenders for the wiring of the Trafalgar Mills. Copies of the specifications and general conditions can be obtained from Messrs. Shepherd and Watney, 71, Albion-street, Leeds, on payment of a cheque for £1. 1s, which will be returned on receipt of a bonâ fide tender. Tenders, endorsed "Electric Lighting," must be addressed and delivered to Messrs. Learoyd Bros and Co., Milnsbridge, Huddersfield, by 12 noon on July 7.

San Juan (Puerto Rico).—H.M. Secretary of State for Foreign Affairs has received from H.M. ambassador at Madrid a copy of a Spanish Royal Order which has appeared in the *Gazette* inviting tenders for the construction and working of a telephone system in San Juan de Puerto Rico. A deposit of 800dol. must accompany each tender which will be considered on August 10. The copy of the Royal Order may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Ealing.—The Urban District Council invite tenders for works in connection with the extension of their electric lighting station at

Digitized by Google

South Ealing. Drawings and specifications can be inspected, and bills of quantities and form of tender obtained, on application at the office of Mr. Chas. Jones, C.E., surveyor to the Council, between 10 and 4, and upon payment of £2. 2s., which will be returned on receipt of a bona fide tender. Sealed tenders, endorsed "Tender for Extension of Electric Station," to be delivered at the office of Mr. Wm. Ruston, clerk, Public Buildings, Ealing, W., by 4 p.m. on July 1.

Rochdale.—Tenders are required by the Free Library Committee for the electric lighting plant required at the free public library, consisting of gas engine, dynamo, wiring, and fittings. Plans may be seen and specification and form of tender obtained at the office of Mr. S. S. Platt. A.M.I.C.E., borough surveyor, on payment of a deposit of £1, which will be refunded on the return of the documents and the receipt of a bona fide tender. Tenders, under cover, endorsed "Free Library—Electric Lighting," must be delivered at the office of Mr. James Leach, deputy town clerk, Town Hall, Rochdale, by 12 noon on 30th inst.

Wallasey.—For condensing apparatus and steam and exhaust pipes in connection with their electric light installation, tenders are invited by the Wallasey Urban District Council. Drawings may be seen, and copy of the specification obtained, on application to the engineer, Mr. J. H. Crowther, at the Gas and Water-works, Great Float, near Birkenhead, on payment of £2. 2s., to be returned on receipt of a bona fide tender. Sealed tenders, on the form provided, addressed to the chairman of the Gas and Water Committee, and endorsed "Tender for Condensing Apparatus, etc.," to be delivered at the office of Mr. W. Danger, clerk to the Council, Public Offices, Egremont, Cheshire, by 4 p.m. on July 16 The contractor will be required to enter into a bond, with approved sureties, for the due performance of the contract.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following: (*a*) the amount of capital which the applicants are prepared to subscribe; (*b*) the system which it is proposed to establish; (*c*) the mileage of lines to be laid; (*d*) the fares to be charged; (*e*) the frequency of the service; (*f*) the length of the license required by applicants; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about 12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

RESULTS OF TENDERS.

Paris.—The contract for the supply of a dynamo at the Buttes-Chaumont generating station has been awarded to the Société Gramme, of Paris, at 4,480fr.

London, S.E.—For engineering work and electric lighting at new public baths and wash-houses, Manor-place, Walworth-road, London, S.E., for the Vestry of St. Mary, Newington, the tender of Messrs. J. F. Clarke and Sons, 49. Moorgate street, E.C., and 41, Featherstone-street, E C., at £6,579, has been accepted.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,900.

Forfar.—The National Telephone Company have begun the work of erecting the alarms for firemen in the burgh.

Aberdeen.—An application from the Harbour Commissioners for the electric lighting of the harbour has been referred to the Electric Lighting Sub-Committee.

Glasgow.—The electric lighting rents of the Corporation were, at the 31st of May, £23 033. 15s. 10d., or an increase of £5,240 on the corresponding period last year.

West India and Panama Telegraph Company.—For the two weeks ended June 15 the receipts were £2,448, as against £2,121 for the corresponding period of 1895.

Windsor.—At a meeting of the Town Council, plans were passed for the conversion of the Albert Brewery into an electric light station for the electric light company.

Worcester.—The report of Mr. Firkins and Mr. Millington on the electric fittings was read at the meeting of the Library Committee, and it was decided to invite tenders for the work.

Rand Central Electric —At a Board meeting, held on Tuesday, the directors of the Rand Central Electric Works decided to make a final call of 5s. per share on all shareholders now registered.

Highgate Hill Tramways, Limited —This Company has been registered, with a capital of £10,000 in £1 shares, to acquire the undertaking of the Highgate and Hampstead Cable Tramways, Limited.

Brush Electrical Engineering Company, Limited. — The transfer-books of the 4½ per cent. second debenture stock of this Company, in view of interest payable on July 1, 1896, are closed until July 2.

Bournemouth.—The Town Council have decided to ask the electric supply company to submit a scheme and estimate for the ordinary lighting of the pier and the illumination of the pier on special occasions

London Extension.—The only notice to come before the County Council last week was one from the House to-House Company to construct a transformer-box in Collingham-place. This was passed by the committee.

The London Tramways Question.—The London County Council discussed at some length at the last meeting the proposals of the tramways syndicate and of the combined companies, and eventually referred the report back.

National Telephone Company.—The transfer-books of the 3½ per cent. debenture stock of this Company are closed until the 30th inst. inclusive for the preparation of the warrants for the half-year's interest due July 1.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending June 21 amounted to £1,221, as compared with £1,245 in the corresponding week of the previous year, being a decrease of £24.

Bangalore.—Five municipal commissioners of the city visited Madras recently with a view to inspect the working of the Madras Electric Tramway prior to making arrangements for a similar tramway service in Bangalore.

Dublin.—The *Belfast News Letter* says it has been announced that the Southern District Tramway Company's electric line from Haddington-road to Dalkey has been purchased by the Dublin United Tramway Company for £273,500

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending June 19 were £2,312. 15s. 9d., compared with £1,860. 12s. 10d. for the corresponding period of last year, being an increase of £452. 2s. 11d.

Barcelona Tramways Company, Limited.—This Company announces the second drawing of its 5 per cent. debentures to take place at the Company's office on July 1; also the closing of the transfer-books of the 5 per cent. cumulative preference shares until July 1 for the preparation of the first half-yearly dividend.

Llandrindod Wells.—Under the title of the Llandrindod Wells Electric Light and Power Company, Limited, a company has been registered, with a capital of £5,000 in £5 shares, to carry on the business of electric lighting in all its branches in the urban district of Llandrindod Wells, Radnorshire.

Wells.—There is some probability of the electric lighting question being brought prominently forward shortly. The Town Council have informed the gas company that the negotiations for the purchase and sale of the gasworks are at an end. This, therefore, leaves the question of lighting open to the advocates of the electric light.

City and South London Railway.—The returns for the week ended June 21 were £836, compared with £794 for the corresponding period of last year, being an increase of £42 The total receipts for the half-year terminating as above were £23,178, compared with £23,093 in the same period of the preceding year, being an increase of £85.

Eastern Extension, Australasia, and China Telegraph Company.—The coupon on this Company's 5 per cent. Australian Government subsidy debentures due July 1 will be paid on and after that date at Messrs. Barclay, Bevan and Co.'s bank, 54, Lombard-street, London, E C. Coupons must be left three clear days for examination.

Dublin.—The Select Committee of the House of Commons which is presided over by Sir Stafford Northcote, is still hearing evidence on the Bill promoted by the Dublin Southern District Tramway Company. A lecture on the past, present, and future of electricity, and its application to Ireland, was delivered recently at Wellington Quay by Captain O'Connor.

Salford.—Some 460 employés of W. T. Glover and Co., electrical cable makers, Springfield-lane, were entertained at a tea and dance on Friday, June 12, to celebrate the completion of the new building at the Springfield-lane works. Mr. Henry Edmunds and Mr. Godfrey B. Samuelson, the principals of the firm, presided at the tables, accompanied by Mrs. Edmunds and Mrs. Samuelson.

Erratum.—In our last issue, page 682, in Mr. Lobley's paper on "The Electric Lighting of Hanley," it is mentioned that Mr. Lobley had "devised a method for lighting incandescent lamps in parallel without sending round the lamplighter." In some inscrutable manner the word "gas" inserted itself between "incandescent" and "lamp," though, of course, the context shows that electric lamps were meant.

Blackwall Tunnel.—The committee of the London County Council have passed the application of the National Telephone Company for permission to lay a 50 twin-wire cable through the subways of the Blackwall Tunnel and erect posts on each side of the river for distributing purposes. The rent to be charged is £5, a free exchange wire from the Council's offices on Northumberland Wharf and free wires between the ends of the tunnel.

Sunderland.—Mr. William Mills, the inventor and maker of patent gear for ships' boats, has commenced an aluminium foundry at the Atlas Works, Bonner's Field, Monkwearmouth, and a number of invited visitors have inspected the novel operation of casting bed-plates for electrical machinery in an aluminium alloy, one set of bed-plates, dynamo-plate, and upper case to support the cylinder though of ample strength, only weighing 1½cwt. in all.

Digitized by Google

East Hanningfield.—The rectory has been fitted by Mr. G. W. Clarke with the electric light. The plant is fixed in the adjacent roller mills, which are also lighted by electricity, and consists of a Crompton dynamo, driven by a pair of high-speed compound engines, by Davey, Paxman, and Co., of Colchester. The current, which is at 100 volts pressure, is conveyed to the rectory by means of a pair of copper cables 600 yards in length, and supported on poles.

New Pinos Altos Company.—In their report the directors of this Company state that the Pelton wheel, by the use of which it was hoped to run the mill during last rainy season, was found defective. The manager however, advised that the installation, as now altered is in such a condition that the Company may rely upon obtaining the full advantage from the present season's rains. The Board are considering the feasibility of putting up a plant for running the mill by electricity all the year round.

Shoreditch.—The Vestry have appointed Mr. R. F. Ferguson construction engineer at the Bankside station, to be resident electrical engineer. Mr. Ferguson was previously engineer at a station under the Brighton Corporation. A proposal has been made to utilise the present gas standards in the side streets for incandescent electric lights of 32 c.p. The tenders for insulated conduit cables, switch and fuse boards, and other fittings and materials, have been referred to the Electric Lighting Committee.

Chelmsford.—The annual sports in connection with the Chelmsford Arc Works took place on the Wood-street Ground on Saturday afternoon. There was an unusually large attendance. The boys of the Essex Industrial School and the workhouse inmates had special free invitations. The band of the former institution, together with that belonging to the town, provided the music, whilst the youngsters also went through a very interesting and smartly executed musical drill. The course was in splendid condition.

Bath.—At the meeting of the Urban Sanitary Authority, Alderman Sturges, referring to the question of the proposed introduction of gas to the statutory hospital, stated that he had heard the people on Combe Down were determined to have the electric light. They were going to employ the late surveyor's son, Mr. Parfitt, who had introduced it in Kingswood and Keynsham. The Council should let the matter rest until they know what the residents on Combe Down would do. In one sense he thought the electric light would be better than gas for the hospital.

Rontgen Photography Tube.—In a note in our issue of June 5 mention was made, under its English equivalent, of the name of the Allgemeine Elektricitäts-Gesellschaft of Berlin as being about to bring out a new form of Röntgen photography tube with which results not before obtained could be produced. We have received a communication from the Electrical Company, Limited, of 122, Charing Cross-road, who are the agents for the German firm in this country, to the effect that the improved vacuum tube is now in regular manufacture by the Berlin firm, and, we presume, can be obtained from the Electrical Company, Limited, in the usual course.

Cardiff.—At the meeting of the Property and Markets Committee Councillor Evans made the sensible suggestion that the borough engineer (Mr. Harpur) should be relieved of the electric lighting supervision arrangements, but the suggestion was not taken up. Because Mr. Harpur is one of the ablest of men, that is no reason why he should be saddled with more work than he can possibly get through with any amount of expedition. At a meeting of the Lighting Committee a letter from Mr. J. H Hallett in reference to his charge for reporting on the plant of the electric lighting station was read. Mr. Hallett reduced his charge from £81. 5s. to £60, which the committee agreed to pay.

St. Pancras.—The second annual outing of the Regent's Park central-station staff took place on Saturday, 20th inst. About 30 of the employés journeyed in brilliant weather to Hastings, where they spent a most enjoyable day. At one o'clock an excellent dinner was served at the Manor Hotel, Mr. T. Cooper, M.A., distributing engineer to the Vestry, being in the chair. At the conclusion of the dinner, before the customary toasts, the chairman read letters of regret from Mr. S. W. Baynes, chief electrical engineer, and Mr. E. Cox, chairman of the Electricity Committee, that they were unable to be present. The party afterwards indulged in various excursions on sea and land, and returned to London in the evening.

West Ham.—The Corporation held a special meeting in committee recently when a scheme for the lighting of the borough by electricity was adopted, only five members voting against it. It was also decided to apply for a loan of £67,000 for the purpose of the installation. Mr. G. H. C. Risch is the engineer for the scheme, and, in the course of the discussion, pointed out that arc lighting for public street-lighting was considerably dearer than gas, but they got a greatly improved illumination. The difference in the cost would be £1,045. The gaslight costs £715, the electric light will cost £1,760; but they would get about 50 times the light. The number of the gas lamps displaced will be 177 single-light burners and five three-light burners.

Swansea.—In reference to the electric lighting of the market it was reported to the Town Council that Mr. John Legg and Mr. John S. Brown had been approached with a view to obtaining estimates. Alderman Tutton, in moving the adoption of the report, said there would be a definite report upon the matter in a short time from Mr. Manville. There was a consensus of opinion in favour of the electric light, which would make the market the finest property of its kind in the country. Two excellent schemes had been submitted to Mr. Manville from Mr. J. S. Brown and Mr. John Legge, and Mr. Manville had complimented the men who had drawn up the reports, and nothing further was required. After some discussion the report was adopted.

Metropolitan Electric Supply.—In reference to the terms of the new issue the *Financial Times* says: "The discontent of a considerable number of the shareholders in regard to the methods suggested by the directors of the Metropolitan Electric Supply Company for the issue of the new capital found a vent in the stock markets. The jobbers interested in the shares on Wednesday took a strong line in favour of the views of certain shareholders propounded at the meeting, and quoted prices with a two-point margin instead of the close prices that have prevailed hitherto." The *Financial News*, on the other hand, points out "that by issuing shares at a premium the amount of the necessary issue is lessened, and the shareholders get a direct advantage from the smaller capital on which dividends have to be paid." The position of the founders' shares is not referred to.

Bury St. Edmunds.—At a meeting convened by the Ratepayers' Association to consider the electric lighting scheme of the Town Council, Mr. W. G. King moved, "That this meeting is of opinion that the present is a most inopportune time for the introduction of electric light into the borough, and protests against the proposed expenditure of £20,000 by the Town Council for the same." It was a hobby taken up by certain gentlemen with the best intentions, but the townspeople did not want to be landed in heavy debt. The financial success of the electric lighting scheme was doubtful. Mr. J. Webb seconded. Mr. H. Bankes Ashton considered that before rushing into so large an outlay as was contemplated relative to the electric light, the emphatic opinion of the ratepayers should be ascertained. He knew of eight towns where there had been a surplus, and 17 where there was a deficit during the last year. For size and importance Bury St. Edmunds was not to be compared with the eight towns where electric lighting had been financially successful. The resolution was declared to be unanimously adopted.

Dover.—The question of the tramways was under discussion at the last meeting of the Town Council. The Town Clerk said that with reference to the petition of the London, Chatham, and Dover Railway Company he had applied to know what they required with a view to meeting them and he found that they required the whole of tramway No. 1 beyond the Crosswall crossing to be abandoned. He declined to accede to that, and he also sought the support of the South-Eastern Railway in the matter. On Friday last he received notice that the London, Chatham, and Dover Company had withdrawn their opposition. He had received a communication from the Board of Trade calling attention to the suspension of the standing order by which corporations were prohibited from working their own tramways, and asking if the Corporation of Dover would wish to work their own tramways. He thought it would be best for the Corporation to reserve the powers to work their own tramways. The town clerk was instructed to reply to the effect that the Council would like to retain the power to work the tramways themselves.

Bedford.—At the meeting of the Urban Sanitary Authority, the Electric Light Committee recommended that the Bedford Gaslight Company be informed that on January 1 next the authority will discontinue to use the gas lamps in the following streets—viz: Kimbolton-road, Glebe-road, Pemberley-crescent, Pemberley-road, (southern end), St. Andrew's-road (except northern part), St. Michael's-road, St. Augustine's-road, Park-avenue (eastern end), the whole of St. Mary's and St. John's parishes lying north-east of the Hitchin branch line, and Cauldwell road. Alderman Richards, chairman of the committee, in proposing the adoption of the report, said there were several streets in the town not mentioned in the list where gas lamps had never been erected, but where they proposed to put electric lamps. Mr. Burridge seconded, and it was carried. The committee further reported that they had obtained the balance of the loan (£17,000) at 3 per cent. interest, the principal being repayable in accordance with the terms sanctioned by the Local Government Board, and recommended that the common seal be affixed to a mortgage for £10,000 part thereof. This was carried.

Hull.—At a meeting of the Electric Lighting Committee the members considered a report by a special sub-committee as to the extension of the electric lighting system. The sub-committee recommend the construction of a new generating station at Sculcoates-lane with plant of 760 h.p., and two sub-stations at Monument Bridge and Park-street. The mains to be laid in accordance with this scheme would be along Sculcoates lane, Queen's-road, Prince's-avenue, Springback. Here they would branch off down Derringham street and Park-street, along the Anlaby-road, through the Boulevard, and then up the Hessle road, Walker street, and Porter-street, from thence continuing the circuit through Paragon Station and Brook-street to the Beverley-road. The committee also recommended a main to be laid down Fountain-road and along Waterloo-street and Charles-street. This, it was estimated, would cost £40,679. With the addition of another system down Bankside, over the River Hull at Sculcoates Bridge, through Chapman-street, and so into Holderness-road, Williamson-street, Hedon-road, Great Union-street, and Witham, the cost would be £50,241. The recommendation of the scheme, minus the East Hull extension, was unanimously approved.

Appointments Vacant.—The Metropolitan Asylums Board require at the Brook Fever Hospital, Shooter's Hill, Kent, S.E., a thoroughly experienced working engineer. Wages 42s per week, with board, lodging, washing, and uniform. Candidates must be able to produce certificates as to their qualifications as practical engineers, and be competent to take charge of and do all

Digitized by Google

ordinary repairs to the boilers, engines, fittings, electric light apparatus, and the lamps and connections thereto, hot-water apparatus, laundry, and other machinery connected with a large and complete hospital. Forms of application can be obtained at the chief offices of the Metropolitan Asylums Board, Norfolk House, Norfolk-street, W.C., where such forms duly filled up, and accompanied by copies (not originals) of three testimonials of recent date must be delivered by 2 p.m. on July 1 —Applications are invited for the following positions to be held under the scheme for intermediate and technical education in the borough of Swansea: (1) lecturer in metallurgy and chemistry; (2) lecturer in physics; (3) lecturer in engineering. The salary offered in each case is £200, rising, by annual increments of £10, to £250 per annum. Particulars as to the duties, which commence in September next, can be obtained from Dr. G. S. Turpin, the principal, to whom all applications should be sent not later than July 4.

Bury (Lancs.). — The buildings at the central station at Whitehead Bridge are practically finished, and are ready for the machinery, which will shortly be fitted. The buildings include a general office, engine-house, accumulator-house, manager's office, showrooms, fitting-shop, and timekeeper's office. In the boiler-house there is accommodation for two boilers, one of which has already been fixed and the other will be fixed in the course of a week or so. There will be four engines in the engine-room, two of which will be of 240 i h.p. each and the others of 38 h.p. each. Four dynamos will be coupled direct to the engines, and there will be an accumulator to take the light load. The laying of the mains is being pushed forward as rapidly as possible. The compulsory supply area is bounded by Moss-lane, Silver-street, Fleet-street, Rock-street, Clough-street, Rochdale-road, King-street, and Princess-street, but it is intended, before long, to extend the supply to Manchester-road, Bolton-street, and Walmersley-road. It is anticipated that the Corporation will be in a position to supply electricity by next winter. The buildings have been constructed by Messrs Storrs and Sons, Stalybridge; Messrs. Siemens Bros, of London, have the contract for the complete installation and lighting; Mr. W. Lord, of Lord-street, has supplied the boilers; and the whole of the work is being carried out under the supervision of Mr. J. Cartwright, the borough engineer.

Leeds. A special meeting of the Tramway Sub-Committee of the Corporation has been held for the purpose of considering the tenders sent in for the supply of the plant required for the proposed Roundhay and Kirkstall electrical tramway. Altogether about 70 tenders were received. A couple of firms sent in estimates to do the whole work. All the other tenders, however, were for one or more of the following—viz., poles and brackets, underground conduits and conductors, trolley wires and attachments, electric motorcars, accumulators and switches, steam engines, dynamos, switchboards and accessories, boilers, and for the building of a generating station. When the full Highways Committee met an hour after the sub-committee had been called together, the latter were not in a position to make any definite recommendations, not having been able to go through all the tenders. So varied were the forms in which the estimates were sent in, that it was impossible for the committee to make reliable comparisons at the moment. They therefore instructed the officials to work out the figures on a similar basis, and to have them ready for a special meeting of the Highways Committee. Should it be found an advantage to let the work in sections, the committee have practically agreed as to what firms should supply the steam-engines, dynamos, boilers, and build the generating station. The tenders which the committee regard with favour for these items of the undertaking amount to about £25,000. The whole of the work is likely to cost between £70,000 to £100,000.

Bingley. — The question of providing additional lighting accommodation cropped up at the last meeting of the District Council. One suggestion, brought forward by Mr. Gatecliff was to increase the storage capacity at the gasworks, and the other alternative was the electric light. Just at the moment they might say it was not wanted in Bingley, and some might ask, How could it be obtained? He had been in communication with the directors of the Leeds and Liverpool Canal Company, and they were perfectly willing to erect storage-rooms at the bottom of the Five Rise and the Three Rise locks, coupled together, and were prepared to make and sell electricity to the Council, the latter undertaking the distribution. There were many points they would have to think about in considering this. The directors believed they could produce an equivalent to 20,000,000 cubic feet of gas, and he had found that this was the amount consumed at the mills and railway station and hotels in the town during the year. Therefore, if those places would take the electric light, the increase of the gasworks would be avoided. It might be urged as an objection, that to adopt this proposal would be making a dual ownership in a public matter, and this was a point for consideration. They wanted now an expression of opinion from the large consumers he had named whether they wished to have the light, and if the Council received any encouragement at all the canal company would send an expert to report and give them particulars how the light could be sold and distributed at a profit. He did not think there was any doubt that the canal company could furnish electricity cheaper than the Council could itself, but whether the suggestion was one which it would be wise to adopt was for the Council and the town to consider. He could not tell them the price it could be retailed at per unit, but certainly it would not have to be more than the price in Bradford, or the idea could not be entertained for a moment.

Belfast.—The *Belfast News Letter* describes the electric light station erected by Messrs. George Combe and Co., of Castle-lane-place, Belfast, to supply current to the Empire Theatre of Varieties. The station, which is fireproof throughout, contains two 45 b h.p. gas-engines supplied by Tangyes, Limited, of Birmingham, which are coupled with 8in. double leather dynamo belting to two 500-light dynamos, constructed by the firm of J. H. Holmes and Co., of Newcastle-on-Tyne Either of these pair of engines and dynamos is capable of supplying all the lights required in the theatre. A large battery of secondary cells by the Epstein Company, of London, supply the day load and any such current as may be required after the performance is over at night. They are charged during the hours of performance, thus enabling the engines to be kept at their most efficient load. The station switchboard is made of polished slate, with heavy teak frame, and carries all the measuring and recording instruments, as well as such switches as are necessary for charging and discharging the cells and the supply of current to the large distributing switchboard on the stage The whole installation, including the wiring and fitting of the theatre itself, has been designed and executed by Messrs. Combe and Co. Besides this installation they have now in hand for Messrs. Wm. Barbour and Sons, Limited, Lisburn, a central station for the supply of some 3,000 16-c.p. lamps, requiring about 300 h.p. Mr. George Combe, the senior member of the firm, acts as consulting electrical engineer to the Harbour Board, and has just secured a similar appointment in connection with the hotel which the County Down Railway are putting up at County Down. Mr. Combe also has a similar engagement with the Belfast Ropework Company, Limited, who are going into electric lighting on an extensive scale. The specification for the lighting of Messrs. Dunville's new premises in Arthur-street was also drawn up by Mr. Combe The firm employs a large staff of workmen, under the superintendence of Mr. John Woodside.

Edinburgh.—The second annual meeting of the Association of County Councils in Scotland was held recently, when the following letter was read from the Postmaster-General on the subject of the use of telephones for police purposes at nominal rates: "The question is one that has already been before me, and I have been in communica ion with the County Council for Fifeshire about it. As the general question of the use of telephonic communication by police authorities is raised both in your letter and in that of Mr. Hope, I may perhaps explain that county councils are at liberty, as hitherto, to arrange with the National Telephone Company for the provision, on such terms as may be agreed either at an annual rental or otherwise, of such services as the Telephone Company under their license from the Post Office are empowered to furnish. Broadly speaking, the operations of the company are now confined to certain districts known as exchange areas, but the company are still at liberty to connect police stations either with exchanges by means of 'exchange' wires, or with other police stations by means of special direct wires. The Post Office is also itself in a position to provide direct wires to connect police stations It is only when the trunk wires connecting separate areas, and provided for the use of the general public, have to be used, that the usual trunk fees have to be charged; and the practical question raised in your letter, so far as it concerns my Department, is whether, when these trunk wires have to be used, special terms can be granted for the use of them. It has been explained in a letter to the Fife County Council that the principle which debars this Department from conceding to any person, or body of persons, special terms in regard to the transmission of ordinary telegrams, applies also to communications over the Department's trunk telephone lines; and the decision that the charge should take the shape of a separate payment for each conversation was arrived at by the Government after very careful consideration of all the circumstances. These circumstances have not altered since the decision was arrived at, and, due regard being had to the analogy of postal and telegraphic services, I fear that I can hold out no hope that her Majesty's Government will be able to entertain proposals for a departure from the principle of uniformity of charge to all users. I much regret that I am not in a position to send a favourable reply to the representations of the county councils of Scotland in this matter. At the same time I may perhaps be allowed to observe that, whilst the taking over of the trunk lines of communication by the State may be productive of some inconvenience in a few directions, the public as a whole will undoubtedly benefit largely by the measure." The association decided to memorialise the Government on the matter, and a small committee was appointed to wait on the Postmaster-General and urge a reconsideration of his decision, with the view of being placed on at least as favourable terms as were enjoyed under the Telephone Company.

PROVISIONAL PATENTS, 1896.

JUNE 15.

13145. Improvements in the construction of ammeters and voltmeters. Thomas James Baker, The Municipal Technical School, Suffolk-street, Birmingham.

13151. Improvements in making and duplicating phonographic records. Henry Rheinlander, 15, Albion-grove, Barnsbury, London.

13195. Improvements in or connected with automatic switches for controlling electric lamps. William James Davy, 40, Chancery-lane, London.

13200. Improvements in or applicable to the charging of accumulators. Axel Gottfried Strömberg, 6, Lord-street, Liverpool.

JUNE 16.

13250. Improvements in telephonic apparatus. Charles Adams-Randall, 93, Chancery-lane, London. (Complete specification.)

13263. A frictional grip for sliding-rods, applicable to holders of electric lamps, carbons, and the like. William Llewellyn Preece, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13264. Improvements in regulating induction electric motors. The British Thomson-Houston Company, Limited, 70, Chancery-lane, London. (Albert H. Armstrong, United States). (Complete specification.)

13267. Improvements in electric switches for street railways and the like. William Ranison Daggett and William Henry Heinz, 18, Buckingham-street, Strand, London. (Complete specification.)

13271. Improvements in electric switches. John Benjamin Verity, 47, Lincoln's-inn-fields, London.

13295. Improvements in or relating to electrically-controlled railway signals. William Phillips Thompson, 6, Lord-street, Liverpool. (Frank McBrien, James Wayland, and James H. Fleming, United States.) (Complete specification.)

13297. Improvements in and relating to electric furnaces. Riccards Pignotti, Ferdinando Lori, Scipione Regnoli, Maffeo Pandaleoni, and Marco Besso, 322, High Holborn, London. (Complete specification.)

JUNE 17.

13339. An improved controlling and feeding mechanism for electric arc lamps. Harold Sisson Jacques, Municipal Offices, Cheltenham.

13405. Improvements in dynamo-electric machines. William Morris Mordey, 46, Lincoln's-inn-fields, London.

13407. Improvements in electrolytic apparatus. Carl Kellner, 46, Lincoln's-inn-fields, London.

JUNE 18.

13449. Improved blasting apparatus for mining and other purposes fired by pressure heat or electricity. Charles Mackintosh, 159, Euston-road, London.

13485. Improvements in telephone switchboards. Isaac Anderson, Robert Wilson Hutchison, and Charlotte Ellen Van Curen, 111, Hatton-garden, London. (Complete specification.)

13488. Improvements in electric incandescent lamps. Godfrey Bamberg, 33, Barcombe-avenue, Streatham-hill, London.

13496. Improvements in incandescent electric lamps. Edgar Julius Sander and Arthur Clifford, 22, Southampton-buildings, Chancery-lane, London.

13520. Improvements in plates for accumulators or secondary batteries. Charles Pollak, 4, South-street, Finsbury, London. (Complete specification.)

13521. Improvements in the manufacture of carbon anodes for electrolytical processes. Peter Jensen, 77, Chancery-lane, London. (Hans Cappelen and Diderik Cappelen, Norway.) (Complete specification.)

13522. Means or apparatus for use in measuring power in alternating-current circuits. Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

JUNE 19.

13542. The electric typewriter. Michael McGowan, 163, Great Brunswick-street, Dublin.

13553. A hygienic ear-piece for telephone receivers and such like. Gustav Dubbert, 70, Wellington-street, Glasgow. (Complete specification.)

13604. Improvements in traction engines for towing vessels. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (La Société de Traction electrique sur les voies navigables, France).

JUNE 20.

13644. Improvements in electrical accumulators. Francis William Greengrass and Stanley Reynolds Docking, 70, Chancery-lane, London

13646. Improvements relating to electric accumulators or storage batteries and to the manufacture of plates or electrodes therefor. William Henry Smith and William Willis, 11, Southampton-buildings, Chancery-lane, London

13647. Improvements in mechanical telegraphs for ships and the like purposes. Albert Edward Seaton and William Henry Willatt, 15, St James's-row, Sheffield. (Complete specification.)

13688. Improved electrical apparatus for the treatment of air, gases, and vapours. Auguste Eugène Bonna, Alexandre Le Royer, and Paul van Berchem, 45, Southampton buildings Chancery-lane, London.

13689. Improved electrical apparatus for the treatment of air, gases, and vapours. Auguste Eugène Bonna, Alexandre Le Royer, and Paul van Berchem, 45, Southampton-buildings, Chancery-lane, London.

13691. Improvements in propelling and steering apparatus for vessels. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Société de Traction electrique sur les voies navigables, France.)

13645. Improvements in electric wiring and in apparatus for making connection therewith. Joseph Devonport Finney Andrews, 45, Fulham-park-gardens, London.

13690. Improvements in electrolytic apparatus. Alexandre Le Royer, Auguste Eugène Bonna, and Paul van Berchem, 45, Southampton buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1892.

4248. Arc lamps. Brockie. (Second edition.)

15120.* Electric accumulators. Headland. (Amended specification.)

1895.

10930. Electrolysing chloride solutions. Hermite and others. (Second edition.)

10360. Electric switches. Lancaster.

10418. Time-recording apparatus for consumption of electric currents. Wende.

10647. Electric propulsion of boats, etc. New and Mayne.

12404. Electricity meters. Hookham.

12546. Electricity meters. Chamberlain and Hookham and Holden.

12614. Electric railways. Lorrain. (Esmond.)

15664. Electric railway signals. Siemens Bros. and Co. (Siemens and Halske.)

1896.

4845. Arc lamps. Adams.

6625. Telephone receivers. Fippard.

7854. Regulating electric motors. Otis Elevator Company. (Otis Bros. and Co.)

7885. Incandescent electric lamp bases. Devonshire. (Henry and another.)

8228. Electric generators. Siemens Bros. and Co. and Lauckert.

8483. Joints for electric cables. Siemens Bros. and Co. and Dieselhorst.

8659. Electric accumulators. Schneider.

8660. Electric accumulators. Schneider.

8695. Electrodes for accumulators. Majert.
